TRAUMATISMS AND MALFORMATIONS OF THE FEMALE GENITAL APPARATUS, AND THEIR RELATION TO INSANITY.*

GEORGE HENRY NOBLE, M.D.

ATLANTA, GA.

In writing this paper it occurred to me that instead of using the small amount of evidence in my possession to emphasize facts already adduced, an expression of opinion by the alienists and gynecologists of this country and an analysis of their views might aid in reaching a true consensus of medical opinion upon the subject. Accordingly I addressed a number of letters to the superintendents of insane asylums in the United States, and the members of two of the most prominent gyneco- gical societies, in which I requested replies to the llowing questions:

1. Do you regard malformations and traumatisms of the female genital apparatus as causes of insanity?

2. If so, in what per cent. of this class of cases, in whom physical examinations of the genitals have been made with the view of ascertaining the facts, can insan- y be ascribed to these causes?

3. Please state character of malformations and traumatisms, and if any operations were done for their ief..

4. Please state the form of insanity, including hys- eromania and nymphomania.

5. Please state if there were any hereditary tendencies to insanity.

6. *Please state results of operations done for relief* of malformations and traumatisms.

7. Please give the impressions you have received along this line.

These letters were so framed as to offer a free opportunity for the alienists to make negative replies. Much to *my surprise, however,* they have replied in a much larger percentage than the gynecologists, and their answers have been more uniformly affirmative. A few years ago they stood in solid phalanx, bidding defiance to the surgeons and as vehemently denouncing them as in the days of 1864, when Storer, a man many years ahead of his brethren, was denounced with the extreme bitterness *known only to members of a sect who feel that in* their hopeless and helpless condition, they are being driven to newer things by outsiders who possess no knowledge of their art. Storer made his observations from the standpoint of a far-seeing surgeon; he believed that woman's disease in such circumstances was like a mill-stone around the neck of a drowning person; that it keeps them down, and is a barrier which prevents them from rising above the stigma of a diseased mind. He was right, but the alienists opposed his advanced views and held the insane woman in bondage for thirty long years, until, thanks to Milton, Rohé, Hobbs, and others, the constant lashing with facts, scientifically applied, *whipped them into line so* that now they are about to take the subject-matter from the gynecologist's hands. In this way they may have a right, for their opportunities for observing the insane are many times greater than those of the latter, who occasionally meet with cases.

To *the letters sent out there were twelve negative* replies; one alienist simply and emphatically says "No." Another adds that he has never seen an insane woman operated on who has recovered. A rectal surgeon replies, "I do not," but perhaps he never sees the female genital organs except through the rectum.

Drs. McMurtry, Pratt, Fry, Cumston, and Hill are discouraging, the first-named thinks that entirely too much prominence is given to the subject. Dr. Maury, of Memphis, is more decided in his views. He has operated a number of times, but can not recall a case of mental recovery, and stated that his cases of surgical traumatism showed evidence of previous insanity. *Wishing to get at the facts of the subject, I requested* him to write more fully of his cases, which he did, and the letter appears in the tabulated report.

Dr. Cartledge replies: "Briefly, I should say that, except the curable mania frequently accompanying interstitial fibroids of the uterus and which are so often manifest near the menopause, I do not regard diseases in this locality directly a cause of insanity."

From the above statement he evidently does regard these tumors as direct causes, and in this he differs from most opinions. They seem to act in an indirect manner, impairing the general health. This class of tumors is more often associated with insanity, but it is not due to the particular variety of tumor. It is the effect produced upon the uterus, by exciting increased growth of that organ, by keeping it in a state of chronic irritation, engorgement, etc., thus intensifying the nervous phenomena usually arising from the womb. Any other tumor that could develop in the wall of the uterus would *be followed by the same results; for instance,* myomata are not infrequently found to act in the same way.

All but one of the asylum reports are favorable. Some superintendents answer very positively "yes" to the first question, others consider that malformations and traumatisms occasionally are direct or sole causes in a small percentage of cases, but all seem to believe they are exciting or contributing causes, which affect the general health.

---

*Presented in a Symposium on the Relation of Pelvic and Intra-Abdominal Diseases to Nervous Diseases, before the Section in Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, June 5-8, 1900.

A few gynecologists do not hesitate to state they regard them as causes. Among these are W. L. Robinson, Geo. F. Hulbert, Joseph Price, E. F. Fish, E. H. Hyde, G. M. Hughes, J. F. Baldwin, Edward French and others. Some of these consider them to be causes in a small percentage of cases, but the most of them make no qualifications.

Among those who believe them to be exciting and contributing causes or an aid in development of insanity, are R. T. Morris, Walter B. Chase, Bovée, H. M. Hunter, I. S. Stone, Manton, Rohé (recent writings), Hobbs, Humiston, Sherwood-Dunn, F. Blume, Carstens, Moses J. White, Edward Walker and others. This last class is composed of men who do not believe that malformations and traumatisms act as causes, except indirectly, by depressing the general health.

These letters show the views of an array of thinking men whose opinions should demand the confidence of the people. Such a number coming with common consent tells us that no longer can traumatisms and diseases of the female genital apparatus be ignored in the treatment of the insane. Indeed it has been shown that these women do suffer these misfortunes, that they impair the health and indirectly influence the mind in a certain percentage of cases. Then why should they be denied the means of relief? On what grounds can it be prevented? Certainly not on that of injury, for we are told that chronic insanity is not made worse by operation, but upon the other hand, that the patients all gain bodily relief, and 23.52 per cent. recover their minds, and 17.64 per cent. are improved. Hobbs' percentages are higher than this.

The reason why the alienists now support these views and accept gynecology as an indispensable aid in their work is that they have had their eyes opened to the fact that the gynecologist does not operate for insanity, but in pleading for attention to bodily discomforts. On these grounds they meet their fellow-men in suffering and pain. According to the reports received, the percentage of cases to which insanity is ascribed is small. Price, on the contrary, states that it is very large. He is supported by insane-asylum reports, which give from 11 to 20 per cent. I wish to point out as a notable exception, the Buffalo State Hospital for the Insane. Dr. Frederick states that he is informed by the female resident physician that she has never found any malformations nor traumatisms in patients admitted to that institution. The East Michigan Hospital for the Insane has found 81 per cent. suffering from some pathological condition calling for attention; but perhaps in the latter institution a more thorough and methodical system of examination has been in vogue as the subject has been well in hand for several years.

In answer to the third question, relative to the form of malformations, diseases and injuries to the female genital canal, accidents incident to childbearing seemed to occur most often, next infection and preputial adhesions; masturbation and puerperal insanity are recorded as commonly found. The remarkably large proportion of good results from operations is a striking feature even in cases of chronic mania. A few instances are given with no results, but such may be expected when the best success does not exceed 40 per cent. of cures and 26 to 30 per cent. of improvement. One is likely to meet with all failures when he does only a limited number of operations. It is not denied, however, that patients are relieved of physical suffering and distress. Absence of vagina, uterus and ovaries is mentioned several times. I have noticed in my own work that palpable external deformities are more frequently associated with insanity than deformities of the internal genitalia. One woman became melancholic and required institutional treatment on account of absence of the vagina. Before she was mentally affected, she claimed that it was not on her account she wanted a vagina established, as she enjoyed the orgasm sufficiently, but on account of her husband. He was opposed to the operation on the grounds of the danger, but she suspected him of regarding it as a sort of free license for making visits to other women. This seemed to wear on her mind until she became melancholic. Another woman came to me from South Carolina, who had had an occluded vagina for twenty-six years, and eventually became unbalanced. The form of insanity was first confusional delusions and then melancholia. She was completely relieved in a few weeks after the vagina had been re-established by a flap operation, and as soon as she could understand that it was a success, her mind improved with remarkable rapidity. A young woman with a partially developed vagina sought relief, hoping thereby to bring her husband back to her. She was melancholic but recovered after operation on the vagina.

Obstetric lacerations are very potent factors for evil and should not be neglected. The general practitioner and obstetrician should make careful search for injuries of this character, especially in women bearing the stigmata of degeneration or a hereditary tendency to insanity.

Simple displacements of the uterus play a considerable rôle as a contributing factor; this is due perhaps to the fact that many women are subjects of these accidents and therefore that more with hereditary tendencies must necessarily be encountered. Often it is hard to realize that a simple displacement can have such an effect, but when immediate recovery follows replacement, as I have seen, we are constrained to ascribe it to some contributing influence.

While I have never observed any mental derangement in cases of uterus bicornis, uterus didelphys, uterus duplex, etc., Clarke, of Cambridge, mentions these malformations in his letter. My patients with multiplicity of pelvic organs regard themselves as freaks of nature, and express satisfaction thereat, while those with defective development, prohibiting intercourse, are caused domestic trouble and much unhappiness. With one exception those of the latter class became insane.

Gynecologists are divided on the question of heredity. No less an authority than Price says: "Heredity is rare." Gresham H. Hill, D. S. Moon, and George L. Kirby, of insane institutions, put the heredity at a high figure, ranging from 20 to 23 per cent. Hill says that one-third of the women admitted to the hospital have some hereditary tendency, and nearly all who are suffering with disease of the reproductive organs are so affected. T. O. Powell, of Georgia, and others, say it is about as much one way as the other, while other alienists claim that some bad heredity, either insanity, alcoholism, or some kindred condition, must exist, hysteria excepted.

The alienists perhaps are entitled to first credit as being men of a habit calculated to draw out these points, as they see far more cases than gynecologists. So it seems that a bad heredity, degeneracy, or a ne rotic family history, is common to many of these patients.

No particular form of insanity follows these lesions. Simple mania, delusions, kleptomania, confusional delusions, nymphomania, hysteromania and melancholia have all been met with; the last three, increasing in the order named, are the most frequent. I have believed nymphomania a comparatively rare disease, but these letters show a surprisingly large number of cases. Preputial adhesions are regarded as the exciting cause, and cures are reported after separation of the adhesions. However, it is not invariably successful, as a few become hopelessly insane. The largest number of cases seem to come from melancholiacs and nymphomaniacs, and here too the best results are found. Carstens does not operate for hysteria pure and simple. Hystero-epilepsy is mentioned by a few writers, but no particular lesion is given. I have found it more often associated with displacements of the uterus, and rarely attributable to disease of the appendages. This perhaps is a digression, but as it pertains to the nervous demonstration of uterine diseases, it is mentioned.

Manton says: "If disease of the reproductive organs is included, I have seen and operated on quite a number of cases of hysteromania and nymphomania, which were cured or greatly relieved by the removal of diseased ovaries. I cannot say that I have ever seen a case of insanity, mania, melancholia, etc., cured by such operative treatment, but relief has often followed. Hysterical conditions have generally been cured."

Here he strikes the key-note and it is hoped that it will have its influence on the needles, and unscientific removal of the uterine appendages except for the relief of local disease with exhaustion psychosis. Patients who retain normal ovaries suffer less nervous perturbation and psychical symptoms. Hysterical conditions are more often found in traumatisms and diseases affecting the uterus. They may seriously hamper the treatment of the diseased mind and demand attention.

With very few exceptions the writers give glowing accounts of their results. R. T. Morris says: "In properly selected cases apparently due to peripheral irritation in patients without marked hereditary tendencies, and without family-acquired neurotic habits, the results of operations have often been striking."

Doubtless following these precepts will result in brilliant achievements as far as mental recoveries are concerned, and if it were right to operate only for the effect upon the mind, it might be well to select the cases, but it will work hardships upon the mentally incurable to condemn them to continual suffering of physical pain. We operate upon bodily disease in the mentally sound and promise them nothing but bodily relief, why, therefore, should we promise more to the insane when identically the same things are done? We should observe the marked conservatism displayed by Manton and Hobbs, and operate only for local disease and somatic pain; then if mental relief is afforded, as it surely is in a large percentage of cases, more will have been achieved than was promised.

All operators, with three exceptions, no matter what forms or stages of insanity exist, say that the results upon the mind are good, very good, satisfactory, very satisfactory, beautiful, improvement in all, improvement in about half the cases, none made worse, etc., while three, notably Dr. Maury, of Memphis, report no benefit in any of their cases. These gentlemen were unfortunate in having to deal with a few incurables, and doubtless will fare better in the future, as the percentage of cures is estimated at about 38 per cent., improvement 33 per cent., mortality 2.5 per cent. (Hobbs). They should therefore get good results in two out of three cases. Though there was no mental improvement in the cases reported by these gentlemen, they do not deny the relief of pelvic pain; their work was successful from the standpoint of cures of local troubles.

Thus there is a brilliancy in the work unlooked for, and a natural tendency to promise too much to family and friends. One should therefore ever keep before him the remarks of a distinguished surgeon[1]: "Indeed, so frequently have the mental manifestations undergone a decided change for the better that I have now come to look for this almost as certainly as for recovery from the operation," and then adds, "I have never yet seen a patient entirely relieved of her mental disorder as the result of operative treatment."

While a few think that little is to be accomplished by surgical treatment beyond the relief of somatic pain, the great majority believe that it is the physician's duty to examine every insane woman for disease of the pelvic organs and to remedy traumatisms, malformations, and treat inflammatory troubles; that while only one-third, or a little more, receive mental cures, another third gain some relief; as a rule all are benefited locally.

Price says that it has been necessary to remove patients from insane institutions in order to cure them, intimating that the surroundings have a bad effect mentally. He further states that many cases should never have been sent to such places. It is believed that pelvic disease acts indirectly upon the mind, that there are also other powerful factors at work which have great influence, notably heredity, yet in a very large percentage of the letters it is claimed that heredity does not necessarily take part in the causation of insanity. Peripheral irritations and depression of the general health are the ideas as to causation held by the larger number. In inflammatory diseases the percentage of insanity is greater, and this is due, in all probability, to absorption of toxins, not necessarily to pus or pus-producing agents.

Continued elevation of temperature, even of slight degree—one-half to one degree—for months is an active factor, especially when associated with large fibroid tumors. I have observed this when there was nothing to account for the fever but the presence of and the irritation caused by the tumors. In such cases the temperature will occasionally drop to normal on removal of the tumors, and if it again reappear will persist for a day or so only; the insanity disappears with the normal, and reappears with the abnormal temperature, and finally cure results when the fever is ended.

Removal of the normal ovaries in the insane as well as in the sane woman is condemned as not only unproductive of good, but as a factor for serious evil. Dr. David T. Gilliam, however, believes "in removing the essential organs of generation from an insane woman during the child-bearing period, upon the broad principle that the world should not be peopled by the progeny of such, both for the sake of the offspring and the world at large." I presume that as the word "insane" is used without modification he intends it to be applied only to the incurable. Robert T. Morris says: "In insane asylums and institutions for the cure of drug habitués there is regularly a percentage of cases that are completely curable by operation. My impression, amounting to a conviction, based upon careful observation, is that patients curable by operation are not apt to be comprehended, are often never examined, and further, that a vista of enlightenment is just beginning to open for men who should be, for the best interests of their patients, in insane asylums and institutions for the cure of drug habitués."

---

[1] Manton.

Dr. Van de Veer said, when asked his impression: "Try some operation in every case." He does not believe that traumatisms and malformations contribute to insanity, but the good effects of operations have not escaped his eye. A few others who are not prepared to acknowledge any connection as etiological factors, do not deny the benefits that have been accomplished by surgery. It is a mistake to carry the principle announced by Dr. Van de Veer too far, for fear of encroaching upon the grounds of empiricism, by removal of normal organs. The latter, as stated, is to be deplored. He surely did not intend that his statement should be spread as a blanket alike over ills, real and imaginary.

Very little is said in reference to post-operative insanity. It is mentioned, under the head of surgical traumatisms, but the impression is that they are more often temporary melancholia or hysteria, and that they usually occur in predisposed subjects or in the puerperal state; the latter being influenced in many cases by septic infection. In one case I operated on, in the second week of the puerperium, for complete tear of the perineum, the insanity did not appear until after she had fully recovered from the operation and attempted to take bodily exercise. I was informed that she lost an excessive amount of blood at her confinement, which must have been true, as she was almost exsanguinated when I saw her. In this case there was no sepsis, but extreme anemia, which did not show its bad effect upon the brain until she assumed the upright position. Her recovery was prompt and kept pace with the increase in red blood-corpuscles and hemoglobin. In this case the operation had nothing whatever to do with the cause of the insanity, but if it had not been done, I believe the bad effect of the complete laceration and involuntary evacuation from the rectum would have produced, in connection with the anemia, a very pronounced mental disturbance.

I have noticed that the violent post-operative nervous changes following hysterectomy are more apt to occur in women whose wombs have grown to a large size. Patients with pedunculated fibroids and small wombs are not apt to suffer in this way. The nearest to an exception to this proposition in my experience was a case of carcinoma of the fundus uteri, in which the womb was about six times its normal size. Although of a very neurotic family, the patient made a good recovery, but succeeded in nearly worrying the life out of her physician and family for eighteen months before showing any signs of improvement. Another strange feature is that insanity existing before the removal of these tumors is often instantly relieved, while, on the other hand, insanity following the operation may be weeks or months developing.

Dr. J. F. Baldwin says: "Occasionally insane cases are made worse by operative interference." Manton claims they are not: and others speak as though operations are not to be feared in these subjects.

Hobbs' impressions are: "Organic lesions of the inflammatory type are the most prominent factors among pelvic diseases in exciting mental alienation, and displaced organs rank next in importance, and tumors last in the order of causation." . . . "that neglect of gynecic surgery in any institution for the treatment of the insane is a serious omission, as where so many women are congregated together there must exist many cases of unsuspected, and, if not investigated, untreated, forms of pelvic disease."

The gynecologist is to-day curing cases of nerve exhaustion or neurasthenia in which the neurologists have failed, by correcting pelvic lesions in addition to the general treatment. We know that the gynecologist repairs injuries, replaces organs, removes septic centers, and couples with them rest and seclusion, with the best results. In many of these cases the neurologist, from prejudice or lack of skill, fails to recognize the disease in the pelvis. I have in mind a patient with grave hysteria and neurasthenia who suffered many things of many men and at last fell into the hands of a neurologist, who declared, after a most careful examination, that she had no pelvic disease. He failed utterly, but fortunately her uterine displacement was recognized by another man, and immediate relief followed his treatment.

We know that cure of disease of the female genital organs is a most valuable and essential aid in the treatment of many nervous troubles in the sane woman; why therefore, have we the right to deny insane women the privilege her more fortunate sister receives?

THE CAUSAL RELATION INTRA-ABDOMINAL DISEASES BEAR TO NERVOUS DISTURBANCES RECOGNIZED BY GYNECOLOGISTS, IGNORED BY NEUROLOGISTS.

HENRY O. MARCY, M.D.
BOSTON.

Perhaps the most difficult of subjects for the master to teach or the student to master are the reflexes of the nervous system and their influence upon the functions of the various organs. In a certain sense are we not yet students?

That all-pervading, ever-acting force that from infancy to old age should hold in stable equilibrium the harmonic rhythm of the individual, for want of a better term we may designate "vital." This life power we know has its definite limitations, although, as one forecasts the future of the individual, he is aware that it must be expressed in the unknown terms of the algebraic formula "x+y" or "x—y." If in health it is so difficult to graduate and measure the possibilities of the individual or determine his daily perturbations within the limit of normal function, how much more abstruse is the problem to detect and to judge aright the pathologic, which it is a part of the daily duty of the conscientious physician to take into careful consideration!

These problems are as old as the mental development of man, and have been coincident with history. F generation views them with new interest, and it is ve probable that certain of their most abstruse factors will remain unsettled as long as modifying conditions and influences produce such infinite kaleidoscopic variatio

*Presented in a Symposium on the Relation of Pelvic Intra-Abdominal Diseases to Nervous Diseases, before the [illegible] on Obstetrics and Diseases of Women, at the Fifty-first Annu Meeting of the American Medical Association, held at Atlantic C N. J., June 5-8, 1900.

in man's development. Science brings about marvelous changes, and we speedily learn to look with equanimity on the acceptance of a new truth, although at variance with our earlier teaching. At a not remote period, heat, light and electricity were looked on as independent and non-convertible forces. He who gave us the key to the transmutation at will of one force into three different forms of physical energy opened the gate into a highway leading to new development; energies coexistent with the life of the planet, but harnessed anew for a higher civilization, the possibilities of which no man may yet estimate.

This individual, vital energy which we call life, has an existence in kind throughout the entire animal kingdom. To man is given, although not exclusively, but in a much greater degree, the power of transmutation of physical force into mentality and that higher efflorescence of its stable equilibrium—mortality—the soul life, the most intangible, the least understood, but in general acceptation, the one enduring factor of existence.

If the physiologic conditions which attend normal development are kept in proper equilibrium, the life machine which we call the body has extraordinary possibilities of energy, and one of the secrets of the largest outcome in its usefulness is the symmetry and correlation of its developing powers. Unduly stimulated, in a certain direction, we look on the brilliancy of this force in the exhibition of its powers as phenomenal and say this is genius. But encouraged too much in this direction we soon find that it may develop into an eccentricity, even an excrescence of character out of equilibrium, and become a positive, individual weakness. This may easily become pathologic, and our state prisons and asylums for the insane are filled with individuals who are sad illustrations of a force unbalanced, primarily due to deviations in mental acquirement.

If the basic, physical conditions become changed, it necessarily follows that greater or less perturbations will be manifested in the mental product. Here, fortunately, we have the guardianship and control incident to the earlier individual development, which project upon the lines of activity, certain influences which we call habits—in other words, doing an act because we have been trained to do it. An illustration: co-ordination of muscular movements, forms of thought, expressions of speech, etc., pertain, in large measure to, and are under the control of, the cerebral functions. These, again, must operate through certain avenues, the spinal nerves, their centers and ramifications, the sensory and other subordinate organs.

An individual in normal health may be defined as one in stable equilibrium between waste and repair, the organism as perfect as the day previous less the age of the machine, plus the product of possible mental and moral increment. Viewed from this standpoint, a defect in the equilibrium of physical forces lessens normally the life product. The reparative processes interfered with from even a temporary defective digestion and nutrition may so change the normal judicial equilibrium as to lessen the value of the opinion of the physician or the clerical adviser, as to influence the verdict of him who holds the life of the criminal in decision, or as to lose the battle to the general. If simple transitory perturbations of nervous or mental force are thus easily affected, what may we not expect when some one of these avenues of life force becomes permanently distorted? These are the wrecks that daily come under the supervision and care of some of us here gathered.

In the subdivision of our various labors, it is but natural that we view the objects through the media to which we are most accustomed. Thus the ophthalmologist, having so often traced the persistent headaches and mental discomfort incident to astigmatism, is likely to think that some visual error is the cause, and will perhaps demonstrate the truth of his opinion by the relief which follows the wearing of properly adjusted glasses.

The physician will weigh carefully the equilibrium between waste and repair, examine with care the digestive and assimilative organs and attribute, with much wisdom, certain defects to lack of nutrition, and to improper and irregular work of the various functions.

The careful student of mental diseases, who should be first a good physician and something more, may view with hopeless equanimity, conditions which he ascribes less to perverted than to ruined forces, and may condemn the individual to a passive restraint.

The surgeon, ever on the alert for some new interposing factor which may have disarranged the machine, seeks to find and remove, often with surprising results, the foreign element which is the cause of the perturbation.

The wise gynecologist should be the physician and something more, the surgeon and something more, since he has under careful consideration another set of organs in addition to those already under discussion, designed for the reproduction and perpetuity of the race. Here enters that subtle factor which has been called, "a normal and constant contribution of specific material by the reproductive glands to the blood or lymph and thus to the whole body." This recent physiologic theory, of so-called internal secretion is an abstruse subject indeed, but one that has been long recognized in one form or another.

The physiologic effects of healthy ovaries and the force which they exert through their correlated organs of reproduction dominate in large degree the individual during the greater period of life. At the recent meeting of the Maternal Congress of Mothers, Dr. Oscar Christman, professor in the State Normal School of Kansas, portrayed certain phases of their effects, although his topic was, "Science of Child Study." He attempts a sexual differentiation, but evidently from the study of effects, rather than of causes.

In the joint discussion which was held two years ago before this Section of the AMERICAN MEDICAL ASSOCIATION, much of importance and value was advanced. It was demonstrated that the leading neurologists were not forgetful that in woman they had a special subject of study in reference to their observations of nervous phenomena quite unlike those of men. Several gentlemen who took part in the debate were generous enough to accredit the gynecologist a service of the highest value which he has rendered by his contributions, demonstrating the relationship of sexual disease to nervous and mental phenomena.

For many years I have advocated the necessity of the study of pelvic and abdominal diseases among the insane and have urged the superintendents of different asylums to institute a careful methodical examination of every patient. Although this special phase of the subject is to be prominently brought before you by Dr. Carpenter, I can hardly do less than refer to one of the most valuable contributions yet offered upon this subject, by Dr. R. M. Bucke,[1] superintendent of the Asylum for the Insane at London, Ontario. It may be women eat for two. It is a matter of common observation that the healthy pregnant woman eats a great deal more than at any other time. While she is saved the elaboration of part of the food by the fetus, still her excretory organs are called on for double duty. If the fetus does not consume the extra amount that she has put into her blood, she has to dispose of it herself as best she can. In the vast majority of cases the first danger-signal which Nature gives us is trouble with the kidneys, but there are many cases of eclampsia in which the kidneys themselves are perfectly normal. These are exactly like the case of the horse that falls in the street. There has been more food put into the circulation than the mother and child combined can possibly dispose of. In those cases where kidney trouble appears, the kidneys have resented this extra amount of work, and in their weakened condition have allowed the germs to lodge. This most awful disease is very simple and easily understood when we think of it simply as a reproduction of what has occurred to the horse just mentioned.

---

[1] President's Address before the American Medico-Psychological Association at St. Louis, May 10, 1898.

Why is it an impossibility for some women, no matter how they are fed or how they are taken care of, to have puerperal eclampsia? My answer is that all such people have a fine eliminative apparatus, and that no matter how much work is thrown on them, they are equal to the emergency. But we all know that the class of people called "gouty" have very poor excretory organs, and consequently allow these poisons to accumulate in their bodies, just as the horse does when standing in his stall.

Haig was on the right track in his analysis of the human family, and has proved beyond a doubt that these defective excretory organs are transmitted from father to son. This rule I have used in the analysis of my cases for years, and from the family history of patients, I can always tell you those who are likely to have nervous troubles from either delayed menstruation or the menopause. Time and again I have been struck with the similarity of symptoms presented by a young girl with delayed menstruation and a woman naturally passing through the change of life. In both cases it is the retention in the blood of material which Nature has stored up to feed the fetus, and no matter what prevents this material from being passed off in the natural way, the patient has a greater or less dose of poison.

As to what these poisons are, I can not yet tell you, for there certainly are a great many different ones. Dr. Rachford, of Cincinnati, has demonstrated that the xanthin bodies produce a great many violent symptoms, and that in menstrual epilepsy they are the specific poisons which produce it. It was very interesting to watch the toxic effect, on mice and guinea-pigs, of this poison obtained from the most severe case of menstrual epilepsy I ever treated. The symptoms were identically the same as those in the patient. Dr. Rachford is still working on the subject, and I hope that we will not only find exactly what these poisons are, but that with this knowledge, we may find a quick way of getting rid of them. His work has been confined to the nitrogenous group, and clinically, I think that is principally at fault. In addition to the presence of paraxanthin, I believe there are a number of the other xanthin bodies which have a great deal to do with it. We now know that xanthin has a great deal to do with rheumatism, and I have cured one case of rheumatism by trachelorrhaphy. The patient had had rheumatism ever since the birth of her youngest child, then two years old. Her joints were crippled, and one knee was especially enlarged and tender. Since the accident she had had intervals of five and six weeks between menstruations. I performed trachelorrhaphy without thinking that it might have any effect on the rheumatism, but, to my great surprise, when she got out of bed, all of her joints were well, and have remained so up to this time, four years after the operation. She was of a markedly gouty diathesis. The injury to the uterus had not only disturbed its time-lock, so that menstruations were delayed and not more than ten a year, when there should have been thirteen, but the inflammation of the organ was so great that menstruation could not be full and free. Not only the thickening of the tissues themselves caused by the invasion of germs, but the chemical action of the ptomains produced by these germs, so changed the blood that the proper amount of elimination was interfered with, thus leaving in the blood many of the nitrogenous bodies which should have been eliminated.

I have had many other cases along the same lines. The repair of an injury or the cure of an inflammation of the pelvis does a great deal to regulate menstruation, and with this regulation comes the relief of headache, migrain, neuralgia, and all the other nervous symptoms. This relief is often assisted by the removal of scar tissue at the time of the operation, but this scar tissue could not cause the general systemic disturbances which most of these patients have. The relief comes gradually in most of these cases, and while each successive menstruation is better and better, still perfect relief does not come for from six months to a year after the operation. This proves to me, in the light of our present knowledge, that the relief is due to the draining of the system of accumulated poisons by perfect menstruation. An ordinary catarrhal endometritis causes many of these systemic symptoms, and, relief does not come immediately after the curetting necessary to cure it, but follows the same rule as the operations I have just mentioned.

I am sure that the majority of nervous symptoms of gynecologic subjects are due to the retained excretions which defective menstruation has failed to eliminate. Another great cause of retention of secretion is the intestinal infection which accompanies nearly all these cases. Given a pelvic lesion which interferes with the menstruation, the reflex wave of the blood-pressure necessary to produce menstruation takes out its force on the intestinal canal, the solar plexus and the other nervous apparatus of the abdomen. This results in a congestion of the whole portal system. Congestion once established, even though it be for only a few days, allows the omnipresent colon bacillus to lodge in the lining membrane of the intestines, both large and small, so that by the time the next menstruation comes on there has been precedent congestion of a part, or the whole of the alimentary tract. The next period is still interfered with by the same lesion, and the blood has not only the ordinary fetal food to get rid of, but also the ptomains which it has taken up from this irritated intestine. The temporary paralysis comes on again, the liver is called on for double duty, and with this vicious circle once established, it is no wonder that by-and-by the liver stops work. This accounts for the indigestion, constipation and general intestinal disturbances that always go with these cases. It also explains why it is that many women who are habitually constipated have a slight diarrhea during the menstrual week. For some reason the uterus has failed to eliminate as it should, and the liver takes up the compensatory work. The older gynecologists found out clinically that these cases did better under free purgation, but now we know the reason for it, and the man who watches the digestive organs carefully will always get the best results.

So far I have been dealing with the nitrogenous compounds, but the starchy foods are also capable of a great deal of mischief. When they are not burned up and converted into carbonic acid and eliminated as they should be, there results the most toxic of their products, oxalate of lime. This substance is troublesome; the symptoms which it produces when left in the circulation are manifold. It is not a trifling symptom, and should always receive due attention from gynecologists.

Nature has one other method of dealing with the starchy foods which has not received its full amount of attention, namely, storing it up in the tissues in the shape of fat. The "hotel anemia" that we are now hearing so much about has as one of its elements this very point of the storing up of fat in the tissues. These lazy, wealthy women, who are not willing to take their share of the troubles of life, and want freedom from care, and all the luxuries without any exertion, either physical or mental, are the ones about whom I speak. Like the goose in preparation for *paté de fois gras,* they are content to do absolutely nothing. In this way not only do their muscles run down, but their hearts become so extremely weak that they are no longer capable of getting up a good menstrual wave. Consequently there is little or no elimination of any kind. They are not only poisoning themselves all the time by the nitrogenous group which we have just been talking about—whence come their neuralgias—but they are not taking exercise enough to burn up the fats. Nature does the best she can under bad circumstances, and stores this up in the form of the obesity which is so commonly seen. This accumulation of flesh is sometimes seen in active women, but they are generally the patients with infantile uteri who have never had a proper menstrual wave, so that the surplus which should have been eliminated by the menstrual wave is left in their tissues in the shape of fat. This also explains the transient fat deposited at the menopause. The hardening endometrium at the age of 45 is incapable of getting rid of all that should be eliminated, and a portion of it is stored up in the tissues; but after Nature has re-adjusted itself and the digestive organs have stopped elaborating the infant's food, this fat is re-absorbed, and the patients are restored to about the same appearance they had before the menopause.

It would be useless before this body to discuss therapeutics. When the main causes of the difficulties have been pointed out, their treatment can be easily indicated. The majority of the bad cases belong to gouty families, and for their management I must refer you to Haig and Dr. Rachford, on the leucomain poisons. Elimination is the key-note of their work. Exercise is only another form of elimination, as it forces a complete oxidation.

In closing let me say, though, that if I have impressed on you the fact that the child-bearing woman always carries a superabundance of food which, if not properly handled, becomes a violent poison in some cases, these few minutes have been well spent.

Study of Leprosy.—Drs. E. Ehlers, of Copenhagen, and Cahnheim, of Dresden, have completed their study of leprosy in Crete, undertaken at the request of Prince George, of Greece. They find the disease a mild type, with a tendency to recovery, favored by the climate, and not spreading. They personally examined nearly 300 cases and estimate the total number on the island at about 700. The authorities are planning a leprosorium on an island off the coast for rigorous isolation of all cases.

TUBO-OVARIAN ADHESIONS—THEIR REFLEXES.*

A. L. BEAHAN, M.D.
CANANDAIGUA, N. Y.

The literature of inflammation of ovaries and Fallopian tubes and the resulting adhesions is copious. Wherever effusion is thrown out, organization of lymph may be expected and the binding of parts together results. The cause is usually complex, and recurring attacks may be anticipated. Each outbreak leaves similar exudates, which develop analagous formations, until the parts may be buried beneath the new-formed tissue. If this process is modified by only one attack of inflammation of moderate intensity, or several recurrences of slight severity, adhesions form of simpler nature, and peristalsis, muscular movements and postural influences will form bands, narrow or broad, between contiguous parts, according to the time elapsing after an attack. Hence pelvic adhesions involving the tubes and ovaries may be divided into two classes, the massive, intensely adherent form, whose removal requires great delicacy and strenuous effort, caused usually by severe chronic suppurative or intense inflammatory tubo-ovarian diseases, and another kind, where structural changes are less manifest, and the diseased organs more easily removed. The first class is readily diagnosed, the latter often requires careful elimination of all other possible causes of disease.

One form always causes a concentration of distress in the pelvis at the original seat of the disease; the other causes vague indefinite local manifestations, and by reflex effects causes insidious, but far-reaching, disturbances at foci removed from the first point at which inflammation was engendered. The first form is ordinarily of gonorrheal origin, the second results with equal certainty from old exanthematic adhesions of the appendages, caused by acute inflammations occurring during adolescence. The former threatens to destroy life suddenly; the latter renders life miserable from puberty to the menopause. Reflex manifestations are most prominently associated with the latter form of tubo-ovarian adhesions, and to this form this paper is especially directed. The literature of tubal and ovarian inflammation of this type is sparse and the diagnosis is difficult.

The pathology of tubo-ovarian adhesions, like that of other pelvic diseases, must follow, and not lead, in our conception of the truth relative to conditions and their direct and indirect sequences. Microscopically, the mucous surfaces of the fimbriæ are agglutinated upon themselves in a club-like mass, or, as is more common, the infundibulum of the tube is fastened to the ovary, as the boy's disc of wet leather is attached to the stone he wishes to raise by a string, and in this position the fimbriæ adhere, yielding only in places, so that the adhesions become of band or string-like character. As temporary adhesions occur normally at menstrual periods, it requires only slight inflammatory exudate to fasten the parts together inseparably. The rupture of small cysts may induce sufficient inflammation to give this effect, and the gross appearance of the disease under consideration is that of a cystic, cirrhotic ovary, with calcareous, sometimes marble-like concretions, the tubes not swollen, as is usually the case, and the uterus undergoing retrograde metamorphosis, if it be not infantile as a result of an exanthema. The guy-line adhesions of tubes to ovaries and the plastering of the fimbriated extremities of the tube to the ovary, or the formation of hematomatous club-shaped masses at the end of the tube, and still a coexistence of string-like adhesions from the ovary to the tube, or from either, to adjacent parts, make a formidable amount of mischief. But such tubes and ovaries are easily raised from their beds, and no such quarrying effort is required to deliver the diseased masses as is usually the case in chronic tubal and ovarian diseases.

*Presented in a Symposium on the Relation of Pelvic and Intra-Abdominal Diseases to Nervous Diseases, before the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

One important aspect of this subject is that the development of tubo-ovarian adhesions is never ushered in by severe symptoms. The pain borne by women at the menstrual periods is not so much increased, when small cysts rupture, as to give rise to suspicions of any serious trouble. The attack of mumps, measles or scarlet fever induces of itself such febrile disturbances and indiscriminate pains that in such cases it is not to be anticipated that the patient will ever after voluntarily allude to this period of her life, with any probability of giving a clear, consecutive history of cause and effect.

It seems probable that when tubercles form on the ovary and tube, the peritoneal attacks resulting therefrom leave a like result. The first indications of disease will be in the remote effects of these underlying causes, which effects act through the sympathetic system on distant organs, which we call "reflex." As it is hardly probable that the history of the case or the local symptoms will indicate the existence of the disease, and as the manifestations are the vague, uncertain expressions of nerve-exhaustion and disturbances of the vasomotor and sympathetic nerve-centers, as well as the higher nerve-centers, it is not strange that effects are considered to be causes and that patients are treated for hysteria, neurasthenia, nerve-strain, dyspepsia and various other lesser forms of enervation. But there is not a loss of will-power in this nerve expression. The outbreaks of nerve-storms at first center about the menstrual epochs, and only when these impressions have been long continued, do the attacks occur at other times.

These patients of nervous organization are never very strong, are subject to fainting-spells, have attacks in which they are motionless, can not talk, and still are conscious. They grow ill and are confined to the bed at intervals, even for weeks at a time. The reflex may involve the head, the stomach and the bowels, giving headache, nausea, constipation, alternating with diarrhea, or the surface of the body may be hyperesthetic, and various pains of neuralgic character may be suffered. Vaginismus and rectal spasms are often present, while eye-strain and nasal obstruction need to be eliminated, that the picture may be clear and distinct. From this description it is evident that great care must be exercised to discriminate between this form of disease and other psychic developments. Given this group of conditions, a careful examination under an anesthetic becomes necessary, and when local disease, such as enlargement of the ovary, with perhaps an infantile uterus, is discovered, and a diagnosis by exclusion reached, it is inferentially clear that radical measures must be used. It parallels the comparatively few cases where complete removal of ovarian disease cures certain mental disturbances, and if we have made a clear case, it proves that certain conditions in women simulating hysteria are due to gross ovarian disease. With enlarged ovaries filled with cysts, hematomata, calcareous masses, or olivary bodies, with small tubes united by string-like adhesions and an infantile uterus, chronic inflammation of the appendages, by inducing harmful adhesions, and a degeneration of ovarian stroma, and atrophy result, in all the reproductive organs. The ovary and tube become useless irritants, capable of much harm, either in inflammatory or reflex effects. If an ovum is thrown off, it must drop into the abdominal cavity, and at the very onset, the whole chain of the menstrual function is demoralized. But so long as the Fallopian tubes remain, the menstrual flow must be provoked, and the profound effects of this half-conceived function be perpetuated.

The adhesions are peculiar to this form of ovarian disease, being of the already described guy-line or band form, so that the rule of removal only when adhesions are pronounced, does not here hold good. But as this form of adhesion may be called reflex, and each hyperemic effect of the menstrual act congests and weights the tube, causing the lines fastening to the ovary to grow taut, or, at intervals, to pull on the adhesions with a jerky hitch, it is easily conceived how, in erectile tissue, such movements without difficulty excite, and finally disturb, nerve-centers. In neurasthenia, or hysteria, in women, chronic invalidism should make the physician carefully weigh the possibility of a concealed cause, and if gross ovarian disease exists with the symptoms recited, the disease is surgical, not medical.

This is a border-line condition, but it does exist, and its cure returns to usefulness an individual who can not engage in any vocation or social function, and who may vainly spend time and means seeking health. Structural disease of the uterine appendages causes insanity. Complete early removal of the diseased organ cures. It is no argument that the cases are considered rare, and that operation has failed to relieve. The exceptions again prove the rule and demand early interference. For the form of diseased appendages, where the reflex is so active and profound, and which is not sufficiently well emphasized and discussed in the available medical literature, but which occurs, and probably more frequently than appreciated, the only sure relief is early operation, ridding the system of diseased ovaries, adhesions and attenuated tubes. The nervous system will then quickly right itself and complete health be restored.

These cases are not so isolated as to be rare, but their pathology needs to be written and their histories to be taken at the bedside, that we may know their bearings.

It is well to emphasize the fact that tubo-ovarian adhesions occurring in the early years of a woman's life may, by reflex, as well as by direct, effects, give through insidious ways obscure nervous symptoms, and a great error will be made if from a lack of a discriminating diagnosis this disturbance is characterized as one where systemic forces alone, instead of local, are at fault. A clean removal of both appendages cures the patient, and a nervous wreck becomes a healthy, happy, useful being.

Yellow Fever at Pinar del Rio, Cuba.—A special order issued from the headquarters, Division of Cuba, July 27, 1900, directed a board of medical officers, consisting of Major William C. Gorgas, Medical Department, U. S. A.; Major Damaso T. Laine, Surgeon, U. S. Volunteers, and Major Marlborough C. Wyeth, Medical Department, U. S. A., to be convened in the office of the chief surgeon of the division at 10 a. m., Saturday, July 28, 1900, or as soon thereafter as practical, for the purpose of examining into the present outbreak of yellow fever among the troops stationed at Pinar del Rio barracks, determining why it was not properly diagnosed and proper measures taken to avoid the spread of the contagion, and to what extent, if any, the post-surgeon should be held responsible therefor, and to submit such recommendations as it may deem pertinent.

GALL-STONES AND DISEASES OF THE GALL-BLADDER AND NERVOUS SYMPTOMS RESULTING THEREFROM.*

EDWIN RICKETTS, M.D.
CINCINNATI, OHIO.

Gall-stones have been found in the bile-duct; in the intrahepatic cells; in adventitious sacs; situated between the hepatic ducts; beneath the ampullæ, and in different portions of the intestinal tract. In subjects of 50 years of age and over they are not infrequently the exciting cause of cancer of the liver and its ducts. Almost as frequently do they cause intestinal obstruction after having ulcerated through and into the duodenum. They are foreign bodies from the intrahepatic cells to the rectal pouch, and are the only foreign bodies in the human economy concerning which many physicians and fewer surgeons persist in teaching the very dangerous doctrine of "hands off" until the resulting death-rate becomes a reflection on our art, worthy of our most serious consideration. Infection coming from the intestinal tract, through the duodenal door opening into the liver by way of the common duct, along with the entering of the bacterium coli commune or pyogenic streptococcus, through the walls of the portal vein, with the shedding of the epithelium from the inner walls of the biliary ducts furnishing a nidus for calculi, are given as causes for the formation of gall-stones.

Gall-stones have passed per rectum during the administration of remedies, from the sugar pellet of one "pathy" to the large doses of olive-oil of another, which proves that its passage was purely coincident, nothing more. With gall-stones recognized early, surgical intervention is to be accomplished by a simple procedure seldom followed by any serious complications; while delayed operations bring complications that oftentimes cause the surgeon almost to wish that he had not been born. Under such circumstances he shoulders grave responsibilities that justly belong to others. If every subject suffering with gall-stones could have the severe attacks of biliary colic with his physician ten miles away, and with a hypodermic syringe working poorly, we should have more timely operations for gall-stones. The graver cases do not always have the acute attacks of colic of the severe jaundice, and yet they lose flesh and strength from the lack of bile that is so necessary to general nutrition and the continual disinfecting of the great body sewer.

Of the forty-six operations on the gall-bladder in private practice, the subjects suffered from peculiar nervous manifestations—peculiar for the reason that they did not know how best to describe them. The following selected case will illustrate fully:

Mrs. C., aged 36, widow, very intelligent, professional nurse, consulted the writer two years ago for a dull pain over the region of the gall-bladder. There were occasionally stools of color and consistency of putty. No morphia has ever been required for pain. She weighed 165 pounds. On examination I found tenderness over the region of the gall-bladder and, on account of a thick abdominal wall, the gall-bladder could be mapped out only with difficulty. Diagnosis: gall-stones. Operation refused. Last March she returned, having lost more than fifty pounds in weight during the previous six months. The skin and sclerotics were jaundiced, and the urine was rather highly colored. During the past two years she had followed her occupation with difficulty; suffered from loss of sleep, and her appetite was poor. There was periodic escape of bile into the intestines, as the stools would show. She was "nervous," as she expressed it, for the reason that she did not have sufficient strength, although until two years ago her health apparently had been perfect.

A cholecystotomy was made and fifty-three small calculi weighing 70 grs. were removed from the gall-bladder and the common duct, together with a dram of pus. The ducts were syringed out with warm water, after which the walls of the gall-bladder and distended upper end of the common duct were curetted gently and then washed out with warm water. A drainage-tube was left in for four days, when bile was flowing into the intestine. The recovery of this patient was most satisfactory. Bile has disappeared from the urine; the wound closed; her appetite is good, and she is rapidly gaining in flesh, while the long-continued nervous manifestations have disappeared.

That there are peculiar nervous manifestations, arising from the action of bile on the nervous system, in all cases in which the flow of bile is obstructed for a longer or shorter time, clinically I am well convinced. I am at a loss to explain the modus operandi, but it is probably nothing more nor less than exhaustion.

PREVALENCE OF GALL-STONES IN INSANE PATIENTS.

Brockbank says: "They occur very commonly in inmates of lunatic asylums, but their presence during life is not usually suspected." He also says that "lunatics are prone to catarrh of the bile-ducts," but offers no explanation. Beadles found in 18 post-mortems on female lunatics gall-stones in 50 per cent.; Snell in 500 females, 19.4 per cent; Warnock in 8 females, 50 per cent., and Goodal in 141 females, 20 per cent. The experiments of Brockbank dispose of the supposition that the so-called saline cholagogues have any solvent action on the gall-stones. Mayo Robson says, "When gall-stones have once formed, no medicine, so far as we know, can dissolve them or produce any material benefit except by way of palliation." Such is the opinion of Hans Kehr of Halberstadt, Germany, who has done more surgery of the liver and its ducts than any other operator.

The literature of the subject is very meager, but the field for future exploration is large. Cushny says in his book on the action of drugs: "Bile when given by the mouth does not cause any symptoms except those from the intestine and liver. When it is injected into the blood, however, it depresses the central nervous system and the heart-muscle, from its direct action on these organs, and decomposes the red cells of the blood. Muscles and nerves suspended in a solution of bile salts rapidly lose their irritability, and some unicellular organisms are also killed and dissolved by them. The poisonous constituent of the bile seems to be the salts of the bile acids, but several authors have stated that the pigment is also active."

"As a cholagogue it is without a rival, but no condition is known in which an increase of the bile secretion is indicated, for although it has been proposed to expel gall-stones by raising the pressure in the gall-ducts by cholagogues, it is found that when the pressure is only slightly increased, the secretion is arrested." He says further, "It is inconceivable that the small rise in pressure could force out an impacted gall-stone." Bile pressure is very low. In Warnock's 44 post-mortems, 43 had marked heart disease. This bears out Cushny in his statement: "When bile is injected into the blood, however, it depresses the central nervous system and the heart muscle from its direct action on these organs, and decomposes the red cells of the blood."

Following the cholecystotomies done by the writer, he, with Brooks F. Beebe, gave a clinical demonstration of calomel in 1/10 gr. doses by the mouth. In every instance the flow of bile was very materially increased; it poured out through the abdominal incision, saturating the dressings and a portion of the bed. A week or ten days later we would repeat the experiment, which was followed by the same results. Our conclusions were that calomel very materially increases the flow of bile after each administration. The results of these experiments were given to the Cincinnati Academy of Medicine soon after.

*Presented in a Symposium on the Relation of Pelvic and Intra-Abdominal Diseases to Nervous Diseases, before the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Before closing, I wish to make a brief report of the following case handed me by Dr. David Riesman, of Philadelphia:

The patient is a professional man, about 30 years of age, whom I saw with Dr. L. W. Steinbach. For a number of years he has suffered from what might be called a chronic bilious state—impaired appetite, coated tongue, heavy breath, sluggish bowels, lack of energy and ambition, and symptoms of mental depression. On several occasions he has had severe pains in the right hypochondrium suggestive of gall-stones, and occasionally he had been jaundiced. A brief cure at Carlsbad, half-heartedly undertaken, did not benefit him. Lately he has become pronouncedly jaundiced, the bowels have been constipated and offensive, the tongue heavily furred, the lips dry, the breath foul, and the appetite in complete abeyance. At the height of this attack he became melancholy, with fear of the future, which seemed to him inexpressibly dark, although from a financial point of view he was very prosperous, and his social position was assured. He became extremely depressed and even began to talk of suicide. Fever developed, which at first was thought to be typhoidal in character, but subsided after ten days. The Widal test and diazo-reaction were negative. He had had an attack of typhoid fever eleven years ago. Before that he had had no trouble with his liver or gall-bladder. The jaundice has now disappeared, the tongue is clean, the conjunctivæ clear; and while his mental attitude is not yet one of unreasonable happiness, it is much better than it was, and he no longer harbors any melancholy thoughts. Both Dr. Steinbach and myself looked upon this case as one of autointoxication. There was no doubt a bacterial agency, resident perhaps in the gall-bladder and to the toxin production of the bacteria were added the effects of retention of bile.

PELVIC AND NERVOUS DISEASES.

THE THIRD ELEMENT IN THE EQUATION BETWEEN PELVIC AND ABDOMINAL DISEASE IN WOMEN AND DISTURBANCE IN THE NERVOUS SYSTEM.*

H. A. TOMLINSON, M.D.
SUPERINTENDENT ST. PETER STATE HOSPITAL.
ST. PETER, MINN.

While getting together the material for the study of this subject last year, I was particularly impressed by the fact that epileptic women who were insane and those primary degenerates who were markedly defective and lapsed into dementia during the period of adolescence were practically free from either history or evidence of any menstrual disturbance; also that there were a great many women coming to the hospital, as well as a certain number among those who had been in residence for some time, who were suffering from apparently grave pelvic lesions which had not been recognized before coming to the hospital and of which the patients themselves were not conscious. Further, among those women who complained most of the symptoms of pelvic disease and in whom there was the most intimate association apparent between the pelvic and mental disturbance, the most trivial lesions were present and the slightest departure from the normal in the physical manifestations of the menstrual molimen. Again, almost all of the women who came into the hospital with a history of pelvic disease giving rise to symptoms had received special treatment, generally surgical, but without benefit to their mental condition, as was evidenced by the persistence of insanity and their commitment to the hospital.

As I stated in a former paper,[1] during the past five years in the hospital at St. Peter, these women have been carefully examined and placed on appropriate treatment as soon as admitted; but with no more result, as regards direct influence on their mental condition, than was attained before they came into the hospital. These facts confirmed to my mind a conclusion, before reached from other data, concerning the relation of somatic conditions in general to disturbances in the nervous system; namely, that there must be another factor which determines the association of the different neuroses with pelvic disease in women. This I have designated the third element in the equation; and it may be defined as the nervous potentiality of the woman. I quote from the paper before referred to as follows: "We have not found that there is any particular form of insanity associated with pelvic disease, nor that there is any relation between the intensity of the mental disturbance and the severity of the pelvic disease, and the same holds true in the relation between menstrual disorders and insanity. In those cases where there was a distinct exacerbation of the mental disturbance in connection with the menstrual molimen, the patient was either free from menstrual disturbance or it was very slight. But in all of the cases where there was well-defined menstrual disorder, there was more or less severe physical disturbance. There were 18 cases of infantile uterus among the young unmarried women, and in most of these cases the ovaries were small and hard. These women were, however, primary degenerates[2] and more or less completely demented before coming to the hospital. Among the epileptics there is usually an increase of mental disturbance, and in the number of convulsions during the menstrual period, but those under our care are free from pelvic disease or menstrual disorder. In studying the histories of the 231 women we found that in 10 cases the insanity was attributed to the influence of the change of life, in 19 cases to menstrual disorder and in 15 to pelvic disease. In all of these there was the same want of relation between the severity of the pelvic disease and the intensity of the mental disturbance. In fact, most of the cases, after careful examination and study in the hospital, failed to disclose any evidence of severe pelvic disease or any connection between the insanity and the disease of the generative organs. At the same time, it was quite evident in other cases that if the existing pelvic disease had been recognized and carefully treated in time, the mental breakdown of the woman might have been averted. During the past five years there have been committed to the hospital five women on whom laparotomy has been performed, and some one or all of the generative organs removed for the purpose of curing the existing insanity. In one case the patient was sent to the hospital soon after the operation, as she had torn open the abdominal wound during an outbreak of violence. Her recovery from this accident was uneventful and she got well enough mentally to go home. The other four are still with us and always will be, and during the past ten years there have been twelve other women committed to the hospital on whom laparotomy had been performed for the cure of insanity. They, too, had not been benefited mentally and have since died or are still with us."

---

*Presented in a Symposium on the Relation of Pelvic and Intra-Abdominal Diseases to Nervous Diseases, before the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Tomlinson: Association of Pelvic Diseases and Insanity in Women, and the Influence of Treatment of the Local Diseases upon the Mental Condition, The Journal, Sept. 30, 1899.

[2] I mean by primary degenerate, a defective individual who becomes insane during the period of adolescence and lapses into dementia.

The diseases of the nervous system associated with pelvic lesions and said to be due to them are always functional, and I can not find that the claim has ever been made that gross degenerations in the central nervous system have resulted from disease or lesion in the generative organs of women. While a considerable number of women who come to the hospital suffer from pelvic disease or menstrual disorder, these conditions and their influence on the mental state of the woman seldom form a part of the clinical history of the case before admission. But when we consider the intimate association between the nervous system and the functional activity of the generative organs in women, and the further fact of the association of arrested development in the generative organs with instability or defect in the nervous system, it is easy to understand why these disease-conditions should stand in apparent causative relation with each other. This associated defect is frequently so marked in primary degenerates, that the uterus and ovaries present all the characteristics of senility, while menstruation is either scanty, delayed, or sometimes absent for long periods. In two cases in this hospital, both primary degenerates, admitted during the period of adolescence, there was a history of infrequent and scanty menstruation from the advent of puberty, and with the outbreak of mental disturbance, menstruation ceased entirely. In one case this amenorrhea has lasted three, in the other, two years, and there has been neither physical nor mental evidence of the recurrence of the menstrual molimen. Again, in this class of cases, it is the rule for the advent of puberty to be delayed, the average being 17 years; and yet no one at all familiar with insanity would think of attributing the mental disturbance accompanying the progressive degenerative changes in the nervous system in these cases to menstrual disorder. However, it is not uncommon to see young women with unstable nervous systems, whose uteri have been curetted or their ovaries removed with the object of curing a condition dependent upon progressive degeneration in the nervous system; because the physician, while recognizing the intimate relation between the nervous system and the generative organs, failed to see that the pelvic symptoms were dependent upon the degenerative process in the nervous system, and that both were due to defective development.

The study of the life history of animals shows that in the lowest types, the life of the female is constituted in the generation of offspring and that all the activities of the adult organism are directed to that purpose. In the higher animals and man, while this absorption of the somatic activities in the reproduction of the species is apparently not so complete, yet it really is so, but presents a different aspect, because of the alterations in the nature and capacity of the organism resulting from changes in environment and the increased complexity of the activities involved. In the human species the largest share of the energy of the mother is devoted to the preservation of her offspring until they become self-sustaining, and we know from the history of civilization that this period of helplessness has grown progressively longer in proportion to the increasingly complex environment of the human being. Along with these changes in the way the female of the human species has been conditioned, corresponding changes have occurred in her organism and especially in those activities involved in the process of maternity. Conspicuous among these changed and increased activities have been the growing influence of the nervous system upon the cycle of maternity and the converse of this influence in the untoward effect of the stress and accidents of maternity upon the nervous system. The resistance of the organism has been lessened in every direction, so that along with greater capacity to feel has come the tendency toward exaggeration of those sensations and activities which were pleasurable or negative, until they become painful.

While the greater development of the nervous system has increased the capacity of the organism to respond to the incident forces in its environment, it has also made active in consciousness those sensations which result from visceral functioning and which under more primitive conditions were not evident, but now respond excessively to slight stimuli and become conspicuous because defect in their structure interferes with the proper performance of their function, or disease makes their activity strenuous and distressing. Analogous proof of this change is found in the life history of the higher domestic animals, which are placed under artificial conditions as the result of in-breeding and unnatural surroundings. What horses and cattle gain in beauty of form or special capacity they lose in hardihood; because those characteristics which depend upon the greater activity of the nervous system are developed at the expense of the rest of the organism.

The function of maternity in the female of the human species has, as a result of civilization, grown from a simple physiologic to a complex and largely pathologic process, and conspicuous among the changes which have resulted are disturbances of the function of the nervous system, manifested by pain, excessive emotional mobility, and aberration from the normal plane of mental activity. If the conditions of modern civilization have brought about this result in the average woman, it is not surprising that we should find an exaggeration of these manifestations in the unstable and defective. These women have for a common characteristic, excessive cerebral mobility, either resulting from inherited imperfections of structure, or acquired causes of instability; they are constantly affected to an extreme degree by disturbances, which although trivial in their nature, have an exaggerated effect on their unstable, mental equilibrium, making the everyday trials and disappointments of life, which are borne by the average woman with equanimity, insupportable calamities and the resultant excessive emotional activity produces extreme mental irritation and physical exhaustion. Should one of these outbreaks occur during a menstrual period, it would be quite natural that some physical disturbance should occur, either in the form of headache, dysmenorrhea or amenorrhea. The recurrence of these conditions with any degree of frequency would of course soon establish a typical neurosis associated with the menstrual molimen. Again, should this association occur in connection with the cycle of maternity or in the presence of chronic pelvic disease, a neurosis or psychosis might easily be established, the permanence of which would be determined by
of defect in the nervous system of the woma

he, with Brooks F. Beebe, gave a clinical demonstration of calomel in 1/10 gr. doses by the mouth. In every instance the flow of bile was very materially increased; it poured out through the abdominal incision, saturating the dressings and a portion of the bed. A week or ten days later we would repeat the experiment, which was followed by the same results. Our conclusions were that calomel very materially increases the flow of bile after each administration. The results of these experiments were given to the Cincinnati Academy of Medicine soon after.

Before closing, I wish to make a brief report of the following case handed me by Dr. David Riesman, of Philadelphia:

The patient is a professional man, about 30 years of age, whom I saw with Dr. L. W. Steinbach. For a number of years he has suffered from what might be called a chronic bilious state—impaired appetite, coated tongue, heavy breath, sluggish bowels, lack of energy and ambition, and symptoms of mental depression. On several occasions he has had severe pains in the right hypochondrium suggestive of gall-stones, and occasionally he had been jaundiced. A brief cure at Carlsbad, half-heartedly undertaken, did not benefit him. Lately he has become pronouncedly jaundiced, the bowels have been constipated and offensive, the tongue heavily furred, the lips dry, the breath foul, and the appetite in complete abeyance. At the height of this attack he became melancholy, with fear of the future, which seemed to him inexpressibly dark, although from a financial point of view he was very prosperous, and his social position was assured. He became extremely depressed and even began to talk of suicide. Fever developed, which at first was thought to be typhoidal in character, but subsided after ten days. The Widal test and diazo-reaction were negative. He had had an attack of typhoid fever eleven years ago. Before that he had had no trouble with his liver or gall-bladder. The jaundice has now disappeared, the tongue is clean, the conjunctivæ clear; and while his mental attitude is not yet one of unreasonable happiness, it is much better than it was, and he no longer harbors any melancholy thoughts. Both Dr. Steinbach and myself looked upon this case as one of autointoxication. There was no doubt a bacterial agency, resident perhaps in the gall-bladder and to the toxin production of the bacteria were added the effects of retention of bile.

PELVIC AND NERVOUS DISEASES.

THE THIRD ELEMENT IN THE EQUATION BETWEEN PELVIC AND ABDOMINAL DISEASE IN WOMEN AND DISTURBANCE IN THE NERVOUS SYSTEM.*

H. A. TOMLINSON, M.D.
SUPERINTENDENT ST. PETER STATE HOSPITAL.
ST. PETER, MINN.

While getting together the material for the study of this subject last year, I was particularly impressed by the fact that epileptic women who were insane and those primary degenerates who were markedly defective and lapsed into dementia during the period of adolescence were practically free from either history or evidence of any menstrual disturbance; also that there were a great many women coming to the hospital, as well as a certain number among those who had been in residence for some time, who were suffering from apparently grave pelvic lesions which had not been recognized before coming to the hospital and of which the patients themselves were not conscious. Further, among those women who complained most of the symptoms of pelvic disease and in whom there was the most intimate association apparent between the pelvic and mental disturbance, the most trivial lesions were present and the slightest departure from the normal in the physical manifestations of the menstrual molimen. Again, almost all of the women who came into the hospital with a history of pelvic disease giving rise to symptoms had received special treatment, generally surgical, but without benefit to their mental condition, as was evidenced by the persistence of insanity and their commitment to the hospital.

As I stated in a former paper,[1] during the past five years in the hospital at St. Peter, these women have been carefully examined and placed on appropriate treatment as soon as admitted; but with no more result, as regards direct influence on their mental condition, than was attained before they came into the hospital. These facts confirmed to my mind a conclusion, before reached from other data, concerning the relation of somatic conditions in general to disturbances in the nervous system; namely, that there must be another factor which determines the association of the different neuroses with pelvic disease in women. This I have designated the third element in the equation; and it may be defined as the nervous potentiality of the woman. I quote from the paper before referred to as follows: "We have not found that there is any particular form of insanity associated with pelvic disease, nor that there is any relation between the intensity of the mental disturbance and the severity of the pelvic disease, and the same holds true in the relation between menstrual disorders and insanity. In those cases where there was a distinct exacerbation of the mental disturbance in connection with the menstrual molimen, the patient was either free from menstrual disturbance or it was very slight. But in all of the cases where there was well-defined menstrual disorder, there was more or less severe physical disturbance. There were 18 cases of infantile uterus among the young unmarried women, and in most of these cases the ovaries were small and hard. These women were, however, primary degenerates[2] and more or less completely demented before coming to the hospital. Among the epileptics there is usually an increase of mental disturbance, and in the number of convulsions during the menstrual period, but those under our care are free from pelvic disease or menstrual disorder. In studying the histories of the 231 women we found that in 10 cases the insanity was attributed to the influence of the change of life, in 19 cases to menstrual disorder and in 15 to pelvic disease. In all of these there was the same want of relation between the severity of the pelvic disease and the intensity of the mental disturbance. In fact, most of the cases, after careful examination and study in the hospital, failed to disclose any evidence of severe pelvic disease or any connection between the insanity and the disease of the generative organs. At the same time, it was quite evident in other cases that if the existing pelvic disease had been recognized and carefully treated in time, the mental breakdown of the woman might have been averted. During the past five years there have been committed to the hospital five women on whom laparotomy has been performed, and some one or all of the generative organs removed for the purpose of curing the existing insanity. In one case the patient was sent to the hospital soon after the operation, as she had torn open the abdominal wound during an outbreak of violence. Her recovery from this accident was uneventful and she got well enough mentally to go home. The other four are still with us and always will be, and during the past ten years there have been twelve other women committed to the hospital on whom laparotomy had been performed for the cure of insanity. They, too, had not been benefited mentally and have since died or are still with us."

*Presented in a Symposium on the Relation of Pelvic and Intra-Abdominal Diseases to Nervous Diseases, before the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, -8, 1900.

[1] Tomlinson: Association of Pelvic Diseases and Insanity in Women, and the Influence of Treatment of the Local Diseases upon the Mental Condition, The Journal, Sept. 30, 1899.

[2] I mean by primary degenerate, a defective individual who becomes insane during the period of adolescence and lapses into dementia.

The diseases of the nervous system associated with pelvic lesions and said to be due to them are always functional, and I can not find that the claim has ever been made that gross degenerations in the central nervous system have resulted from disease or lesion in the generative organs of women. While a considerable number of women who come to the hospital suffer from pelvic disease or menstrual disorder, these conditions and their influence on the mental state of the woman seldom form a part of the clinical history of the case before admission. But when we consider the intimate association between the nervous system and the functional activity of the generative organs in women, and the further fact of the association of arrested development in the generative organs with instability or defect in the nervous system, it is easy to understand why these disease-conditions should stand in apparent causative relation with each other. This associated defect is frequently so marked in primary degenerates, that the uterus and ovaries present all the characteristics of senility, while menstruation is either scanty, delayed, or sometimes absent for long periods. In two cases in this hospital, both primary degenerates, admitted during the period of adolescence, there was a history of infrequent and scanty menstruation from the advent of puberty, and with the outbreak of mental disturbance, menstruation ceased entirely. In one case this amenorrhea has lasted three, in the other, two years, and there has been neither physical nor mental evidence of the recurrence of the menstrual molimen. Again, in this class of cases, it is the rule for the advent of puberty to be delayed, the average being 17 years; and yet no one at all familiar with insanity would think of attributing the mental disturbance accompanying the progressive degenerative changes in the nervous system in these cases to menstrual disorder. However, it is not uncommon to see young women with unstable nervous systems, whose uteri have been curetted or their ovaries removed with the object of curing a condition dependent upon progressive degeneration in the nervous system; because the physician, while recognizing the intimate relation between the nervous system and the generative organs, failed to see that the pelvic symptoms were dependent upon the degenerative process in the nervous system, and that both were due to defective development.

The study of the life history of animals shows that in the lowest types, the life of the female is constituted in the generation of offspring and that all the activities of the adult organism are directed to that purpose. In the higher animals and man, while this absorption of the somatic activities in the reproduction of the species is apparently not so complete, yet it really is so, but presents a different aspect, because of the alterations in the nature and capacity of the organism resulting from changes in environment and the increased complexity of the activities involved. In the human species the largest share of the energy of the mother is devoted to the preservation of her offspring until they become self-sustaining, and we know from the history of civilization that this period of helplessness has grown progressively longer in proportion to the increasingly complex environment of the human being. Along with these changes in the way the female of the human species has been conditioned, corresponding changes have occurred in her organism and especially in those activities involved in the process of maternity. Conspicuous among these changed and increased activities have been the growing influence of the nervous system upon the cycle of maternity and the converse of this influence in the untoward effect of the stress and accidents of maternity upon the nervous system. The resistance of the organism has been lessened in every direction, so that along with greater capacity to feel has come the tendency toward exaggeration of those sensations and activities which were pleasurable or negative, until they become painful.

While the greater development of the nervous system has increased the capacity of the organism to respond to the incident forces in its environment, it has also made active in consciousness those sensations which result from visceral functioning and which under more primitive conditions were not evident, but now respond excessively to slight stimuli and become conspicuous because defect in their structure interferes with the proper performance of their function, or disease makes their activity strenuous and distressing. Analogous proof of this change is found in the life history of the higher domestic animals, which are placed under artificial conditions as the result of in-breeding and unnatural surroundings. What horses and cattle gain in beauty of form or special capacity they lose in hardihood; because those characteristics which depend upon the greater activity of the nervous system are developed at the expense of the rest of the organism.

The function of maternity in the female of the human species has, as a result of civilization, grown from a simple physiologic to a complex and largely pathologic process, and conspicuous among the changes which have resulted are disturbances of the function of the nervous system, manifested by pain, excessive emotional mobility, and aberration from the normal plane of mental activity. If the conditions of modern civilization have brought about this result in the average woman, it is not surprising that we should find an exaggeration of these manifestations in the unstable and defective. These women have for a common characteristic, excessive cerebral mobility, either resulting from inherited imperfections of structure, or acquired causes of instability; they are constantly affected to an extreme degree by disturbances, which although trivial in their nature, have an exaggerated effect on their unstable, mental equilibrium, making the everyday trials and disappointments of life, which are borne by the average woman with equanimity, insupportable calamities and the resultant excessive emotional activity produces extreme mental irritation and physical exhaustion. Should one of these outbreaks occur during a menstrual period, it would be quite natural that some physical disturbance should occur, either in the form of headache, dysmenorrhea or amenorrhea. The recurrence of these conditions with any degree of frequency would of course soon establish a typical neurosis associated with the menstrual molimen. Again, should this association occur in connection with the cycle of maternity or in the presence of chronic pelvic disease, a neurosis or psychosis might easily be established, the permanence of which would be determined by the degree of defect in the nervous system of the woman.

The effect of pregnancy upon the nervous system of the mother and the peculiar susceptibility of women to causes of mental disturbance during the puerperium are so well known, even among the laity, as to have resulted in a definite tradition, with conventional rules for the conduct of the pregnant woman and her environment during the puerperium; because experience has shown that the woman is more susceptible to external sources of irritation at this time and is liable to serious disturbance of physical health, by untoward conditions in her environment, which at other times would be innocuous and especially those which affect the nervous system. These ill effects seem to increase with civilization and its requirements. In other words, along with the increased capacity to enjoy there goes a proportionate tendency to suffer; so that while frequent child-bearing, overcrowding and bad surroundings in the tenement districts of the city, and exposure and overwork in the country among the poor, bring a train of physical ills to complicate maternity, high-pressure intellectual life and social competition have an equally disastrous effect upon the well-to-do. Thus, whatever weakness or defect may exist in the mother is exaggerated by her condition, and what was originally a physiologic becomes a pathologic process, out of which develops a host of conditions, most of which are temporary but that often destroy the physical or mental health of the woman.

When we come to the analysis of case records, however, we can not help being struck by the relatively small number of women who have borne children and in whom pelvic disease has resulted, who become the victims of any one of the different chronic neuroses or psychoses. When we consider further how common it is to find profound neurasthenia or hysteria associated with a slight perineal tear, increased mobility of the uterus or slight malposition, while a fibroid tumor wedged in the pelvis, pus-tubes, or a complete perineal tear, in another case will give rise to no nervous symptoms whatever, there is still further evidence that the lesion of the generative organs is not the cause of the neurosis associated with it.

Two women came under my observation last year who well illustrate the antithesis. One, a young woman, the mother of two children, the child of a consumptive mother, had been highly neurotic as a girl and had suffered from dysmenorrhea. When I saw her she had been in bed most of the time for six months and had all sorts of pelvic and nervous symptoms. She had a small perineal tear and some prolapse of the vagina, but no disease of the pelvic contents, and she menstruated regularly without discomfort except from the nervous symptoms. The other was a woman 60 years old, who was in robust health, without an ache or pain, and who was doing the work of a man out of doors; yet her perineum was torn to the sphincter and the elongated cervix with the prolapsed vaginal wall protruded three inches from the vulva.

In St. Mary's Hospital, Rochester, Minn., where a large number of operations for abdominal and pelvic disease are done every year by my friend, Dr. W. J Mayo, the records show that those women who complain most and have the most marked nervous and mental symptoms in connection with pelvic or abdominal disease, usually have the most trivial lesions, and in nearly all cases where the neurosis and psychosis is attributed to the pelvic or abdominal disease, he has found evidence of attacks occurring before the physical disease existed. Furthermore, he has seldom seen the nervous conditions cured by operation for the pelvic or abdominal disease in this class of cases; athough a temporary benefit may accrue as the result of the preparatory treatment and the period of convalescence, as well as the suggestive effect of the operation itself. In his experience, only those neuroses and psychoses have been benefited which have made their appearance after the onset of the pelvic disease, and which grow worse in proportion to the interference with the physical health and welfare of the woman. The different neuroses were not present in his experience, except in those cases where the personal history of the woman showed pre-existing instability or defect in the nervous organization.

While it is undoubtedly true that a great many women who have an unstable nervous system become insane or the victims of neurasthenia or hysteria in the presence of severe pelvic or abdominal lesions, these disturbances do not take place until the disease has existed for some time, that is, until the general health of the woman has been seriously impaired, her vitality lowered and her resistance materially lessened. Besides, associated with these lesions are usually anemia, septic infection and autointoxication, and usually after these secondary conditions are established, the nervous breakdown takes place. To illustrate: A woman came under my care, transferred from a general hospital where an operation had been done for the removal of pus-tubes. She was 35 years old, the mother of four children and had been in good health until the birth of her last child, three years before. She was and had been highly neurotic and had several explosive outbreaks as a girl, besides presenting other evidences of instability. She had been quite ill for a year before the operation, but passed through it without any untoward symptoms and was apparently convalescing nicely, when, seven days after the operation a stitch-abscess formed in the abdominal wound. The day this was opened she became restless, did not sleep the following night, and in a few days passed into a condition of violent excitement, in which state she came under my care. She had borne successfully the illness resulting from the pelvic lesion and the shock of the operation, but the reinfection from the stitch-abscess, added to the artificial establishment of the climacteric, was too much for the unstable brain and a degenerative process began, which in her case was permanent.

Taking these facts into consideration, it would seem evident that the equation between pelvic and nervous disease is not a simple one, and also, that with the prognosis as x, the third element is the most important; especially when we have to consider the effect of surgical procedure and its potentiality for cure in those cases where pelvic lesion and nervous disease are associated. The functional activity of the general nervous system is manifested in the perception, transmission and relation of external and visceral impressions, and in the co-ordinate discharge of motor impulses in the manifestation of muscular and visceral activity. This adaptation of internal to external relations constitutes the life of the individual, and as the tendency is for all activities which persist to become definite and uniform, most of those which have to do with the vegetative and locomotive functions become automatic and are performed without the active intervention of consciousness. It will be readily understood that the welfare of this mechanism will depend upon its proper nutrition and the abscence of any unusual or excessive strain. Should such a strain occur, the result would be a disturbance of definiteness and uniformity proportionate to the amount and character of the strain, while the persistence of the aberration of function would depend on the degree of interference with nutrition and the relative perfection of the different parts of the mechanism.

The history of the sexual life of women shows that, even among the most healthy, excitement, overwork or emotional disturbance are reflected in disturbance in the function of the generative organs, especially among those in adult life and who have borne children. If these abnormal conditions occur during the menstrual molimen or in the cycle of maternity, they result in dysmenorrhea, headache, emotional outbreaks, or abortion, delirium, subinvolution, leucorrhea and ovarian tenderness; all of which disappear as soon as the general health of the woman is restored to normal. On the contrary, if the nervous organization of the woman is unstable, these untoward effects are exaggerated and tend not only to recur but to persist and become habitual. This is manifested by the change of character, which as a rule is permanent; the failure of memory and attention; and the lessened or lost capacity for continuous mental effort. Even in the mildest cases there is loss of self-control, manifested by impatience, irritability and complete loss of "grit," so that the victim succumbs to trifling disturbances, is exhausted by slight muscular effort, and on account of these conditions becomes abnormally self-conscious, recording all experiences in a staccato key and looking upon every relation in life from the standpoint of individual personality; realizing vividly the responsibility of others toward herself, which she magnifies, but losing sight entirely of her responsibility toward others. These people are most unhappy, living always on a transcendental plane of nervous erethism, magnifying every ordinary sensation into a profound emotion; seeing in every call for muscular effort a herculean task, and resenting the apparent want of sympathy shown in the failure of those around them to appreciate things as they see them; while at the same time their exaggerated egotism makes it impossible for them to realize that there is any standard other than their own.

If I am right in my contention it would follow that the symptoms accompanying pelvic disease and menstrual disorder and referred to them are the result, rather than the cause, of disturbance in the nervous system, and that their variation, intensity and persistence are dependent upon the nervous potentiality of the woman. Therefore, in determining their pathology and considering their management, as well as the prognosis and the effect of treatment of the disease of the generative organs; we should be guided by the data to be obtained from the family, and personal history of the woman, which show the limitations of her nervous potentiality and the nature of its response to the untoward conditions in her environment.

Neuroses and psychoses as they occur in men are quite commonly attributed to disease conditions in, or abuse of, the generative organs, but we do not hear of operative measures being recommended for the cure of the existing neurosis or psychosis. On the contrary, it is fully recognized by those whose experience has made them familiar with the manifestations of insanity, that these disturbances or perversions of sexual function in men are symptoms and a part of the neurosis or psychosis. The gonorrheal infection, which in woman produces a pyosalpinx or hydrosalpinx or pelvic adhesions, in man produces cystitis, pyelitis or septic arthritis. Yet, if these conditions occurred in association with a neurosis or psychosis, they would not be looked upon as causative factors, and we would not expect to cure the nervous disease by operating upon the generative organs; although such an operation might be done for other reasons.

Three men have been admitted to the hospital at St. Peter during the last ten years, the victims of self-mutilation, in all of whom dementia rapidly supervened upon the castration. Their history, however, showed them to be defective individuals, in whom the mental breakdown was the result of the incidence of the ordinary stress of industrial and social competition upon a limited cerebral potentiality at a time when resistance was lessened by privation or disease.

I can not do better in closing than to quote from the conclusions expressed in my paper of last year on this subject: Menstrual disorder and pelvic disease are quite commonly associated with the different neuroses and psychoses, but in my experience they bear no apparent causal relation to the nervous disturbance; nor is the intensity of the nervous disturbance in proportion to the gravity of the physical disease; but on the contrary, the most grave pelvic disease, even among the neurotic and insane, exists without disturbance in the nervous system and frequently without physical symptoms.

In cases where the insanity or chronic nervous disease has existed for more than a year, or the patient has a defective nervous organization, treatment of the disease of the generative organs is practically without effect upon the insanity or neurosis, and in such cases operative interference resulting in the establishment of an artificial menopause almost invariably hastens the onset of dementia.

Operative interference is called for in the treatment of pelvic disease among the insane for the same reasons that would determine the necessity for such treatment among the sane; that is, for purely surgical reasons.

In order to determine whether or not treatment of the disease of the generative organs will have a curative effect on the insanity or neurosis, it is important to know the family and personal history of the patient with regard to the presence or absence of evidence of unstable or defective nervous organization, the length of time the insanity or neurosis and disease of the generative organs have existed, and to what extent the general health of the woman is affected by the pelvic disease independently of the insanity or nervous disease.

PELVIC DISEASE AS A FACTOR OF CAUSE IN INSANITY OF FEMALES AND SURGERY AS A FACTOR OF CURE.

EUGENE G. CARPENTER, A.M., M.D.
Superintendent Columbus State Hospital; Professor Nervous and Mental Diseases Ohio Medical University; Neurologist to Protestant Hospital.
COLUMBUS, OHIO

In considering what we know of the causes of insanity, the unknown quantity represents an equal ratio with that which may be fairly regarded as the known. In the psychiatric revival of the last ten years, the moral causes, upon which so much stress was wont to be laid in the past, have sustained a severe recession.

---

*Presented in a Symposium on the Relation of Pelvic and Intra-Abdominal Diseases to Nervous Diseases, before the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Formerly excessive grief or excessive joy, loss of property or loss of soul, diabolism or sainthood; in brief, any disturbance of the emotions, was sufficient in assigning cause. To-day, in the light of what we know of anthropology, pathologic chemistry, bacteriology, and autointoxication, science has turned to physiologic phenomena for explanation in the disease, insanity. It having been observed in the early history of medicine that many nervous and emotional disturbances in women were associated with disorders occurring at puberty, the catamenia, the puerperal state, the lactic and the climacteric periods, the older observers placed great weight upon these normal physiologic appearances as evidences of pathologic manifestations.

If the insane condition suggests a disturbed brain on the one hand and pelvic disease on the other, an allied pathologic condition would naturally suggest a close anatomic connection and an intimate physiologic association. For what interest it may lend we will briefly rehearse the early development of these two sets of organs and note in how far there is justification for this faith from an embryologic standpoint. The earliest evidence of anything like form in the embryo of organic life is the aggregation of the epiblastic cells about a medullary groove, which ultimately becomes the neural canal; then there quickly follows in the anterior portion of this canal the formation of three vesicles which later go to make up the brain. In the chick all this process occurs wthin the first twenty-four hours. About the forty-fifth hour there appears upon the field for the first time the earliest indication of any cell arrangement in connection with the genital organs, viz., the Wolffian duct, a product of the mesoblastic layer. On the fourth day may be seen on transverse section of the embryonic chick the first appearance of the Wolffian bodies. These are vascular glomerulous structures, and in the human appear to have some connection with the embryologic evolution of the genital organs. They remain functionally active throughout life in some lower vertebrates, but atrophy before birth in mammalia (Quain). However, vestiges remain as the efferent ducts of the testes, the paradidymis and the gubernaculum (Kobelt) of the male, the paroophoron (His and Waldeyer) and the round ligament of the uterus of the female. They seem to establish their identity in these parts of the genital organs. According to Waldeyer ova are seen in the thickened germinal epithelium of the embryo chick of four days. Up to a certain time in the human the external organs are entirely of the same form in both sexes, and the genital organs which afterward distinguish sex have a common origin. At about two and one-half months the genital tubercle projects about 1.5 mm., and has a knob-like end which indicates the future glans penis or clitoris. On its lower surface is situated a groove bounded by the genital folds, which in the female become the nymphæ. At twelve weeks the sex is yet indefinite, and not until three and one-half months is the sex distinguishable. Thus, while the genital apparatus has not taken on its form or function, the brain and cord are long since established in both and preside over all. Flechsig and Edinger, in their investigations in the embryology of the nervous system, have shown that most of the nerve fibers develop their medullary sheaths before the fourth and sixth week. Before the sexual organs have begun to functionate, the various segments of the cord are fixed and established, and are concerned in the evolvement of the very organism of which they are but an embryonic part. It is to be borne in mind in this brief résumé that the entire nervous system, including the peripheral, sympathetic, and splanchnic systems, develop from the epiblast, while the genital and urinary systems take their origin from the mesoblast; that these different systems of organs were formed at different stages of early development; that the function of the generative organs comes into activity later and departs earlier. Furthermore, after the organism is fully evolved, and all its parts fixed in function, that the pelvic organs are formed to be innervated by the lowest centers of the cerebrospinal axis; that their connection with the higher brain centers is indirect and remote; that their functions are largely, if not wholly, involuntary and automatic, as are those of other organs of the viscera depending upon the spinal cord for their innervation. The burden of explanation of these pathologic seemings must needs, therefore, fall upon the sympathetic system, of which we know so little, but whose screen is so convenient when something of a functional character is to be elucidated. In approaching the subject from this standpoint should we not have a care in crediting an inferior organ which has developed under the dominance and supremacy of a higher organ with so great an influence in instituting pathologic processes in that organ? When we consider the distance and indirect path which an impression must pass from the lowest segment of the cord to the highest cortical level, is not the probability scant for minor local lesions or disturbances causing such a degree of irritation as to establish a central psychical disorder?

All the eminent authors, past and present, who have written of mental disease have treated the subject of the relation which disturbances of the genital organs of females sustain to the cause of their mental difficulties.

Hippocrates spoke of the first menstrual effort in this connection. Esquirol says in his text: "Menstruation, which performs so important a part in the economy of women, can not be a stranger to the production of insanity. It even takes a sixth place among physiological causes." He alludes with equal fervor to leucorrhea, the puerperal state and period of lactation. Greisinger and Feuchtersleben, the older German writers, with equal enthusiasm allude to the part which disturbances of the genital organs take as physical causes of mental disease in woman. Clouston recognizes puerperal and lactational insanity as special forms, although other reliable observers discredit these as special types. Maudsley must be added to the list, but modifies his argument as follows: "So frequently is hereditary predisposition more or less traceable in these three forms of insanity—that of lactation, puerperium, and pregnancy—occurring in connection with child-birth, that we are warranted in declaring that it is quite exceptional for any of them to be met with where it is entirely absent." He adds that "disease of the pelvic organs may act as a powerful co-operating cause for the production of insanity without giving rise to any particular group of symptoms." Among the older writers reference is made to special cases of mental disturbance which seem to depend upon pelvic disease. Schröder Van Der Kolk alludes to that of a woman, perpetually melancholy, who was relieved by replacement of the uterus. Fleming also relates cases cured by the employment of pessaries. Since these men wrote, all that is known of asepsis, chemical pathology, abnormal states of the blood in the pregnant condition, and kindred matters, have been added to pathology in general and have become common property in the pathology of the insane state.

As representing the more modern and rational view of this question your attention is called to two authors particularly.

Krafft-Ebing maintains that the influence of diseased generative organs in woman should not be underrated as a physical cause of insanity, and gives them the following order: "1. Uterine trouble, accompanied by chronic inflammatory irritation changes. 2. Neuralgic and hyperesthetic affections of the vagina. 3. Chronic catarrh, hypertrophy, erosions, etc., of the cervix." He holds that malignant disease seldom leads to insanity; that the psychosis presents nothing characteristic; that genital disease sometimes so weakens a constitution that it falls a prey to mental disease, or occurring in a predisposed person, acts as an exciting cause of insanity.

Kraepelin, with no little degree of conservatism, admits a close relationship between psychic conditions and the sexual life, as evinced by the changes in character in the normal development and retrogression of the sexual organs, and in the altered character of the castrated. He regards it, therefore, comprehensible that disease of the sexual organs may have a decided effect on the psychical life. Reference is made by him to the special disposition of women to develop insanity at the climacteric, a period of retrogression and degeneration noted in men as well at the beginning of old age, to the circumstance that operative procedure originated from the fact that certain forms of hysteric insanity improved by treating existing genital disease, and the conclusion was drawn that displacements of the uterus, erosions of the cervix, diseases of the tubes, ovaries and vagina, were actually able to produce insanity, and that hysteria is often the clinical expression of these cases. These cases furnish the list of wonderful cures by operation. We know, however, that the same results are obtained through entirely different, even senseless means, from which we conclude the effect to be a psychic one. In fact, upon the ground of clinical experience to-day, we can say with certainty that disease of the female genital organs leads to insanity only when the ground has been already prepared by disease-predisposition. It is without characteristic clinical features, which are dependent on the constitution of the one affected. We will have to do with some one of the many forms of degeneration insanity. It is noteworthy in the entire matter that the severest diseases of the pelvic organs —the malignant tumors—comparatively seldom produce insanity. When this is the case, they are such forms as occur with all severe disturbances of nutrition.

Since prominence has been accredited the physical element as a factor in the cause of insanity, renewed effort has been made to increase the percentage of recoveries of the insane, but with little promise. Despite the pursuance of lines of treatment in accordance with our newer ideas of pathology, our increase in the list of recoveries is not commensurate with the effort and energy employed. Out of the theory that disease of the pelvic organs of females was responsible for many of the neuroses incident to this class, and out of the fact that some brilliant results have been demonstrated by the use of the knife, that instrument in the hands of the surgeon has been heralded as a therapeutic agent of virtue in the cure of the insane.

The knife as a factor in cure has widened its sphere of action and utility in a number of new fields during the last quarter of a century. The part it has played in the realm of the abdomen, the kidneys, the urinary tract, the organically diseased brain, the stomach and the intestinal tract, has given an impetus to this means of cure, until now the only question arises as to what are the limitations of its real usefulness. In this observation I have reference to the rôle which surgeons play in the cure of insanity by operations upon the pelvic organs of the female.

Neither one nor several successful cases is sufficient to establish a rule of practice. While reports of a considerable number of successes have been recorded, those cases in which failure resulted, and those in which the condition was made worse have no place in publication. The results have been so various that the entire subject is a mooted one, and our object in this paper is to throw some light upon it. On the other hand, most alienists, while granting that cure may possibly follow the use of the surgeon's knife, are not willing to join the ranks of those of such strong faith, but oppose it with a conservatism which they regard as justified by a broad and practical experience. Between these two positions the writer believes there is a middle ground on which all can stand with rationality.

Before endeavoring to indicate what this position should be, it is our purpose to present some practical results of operations gleaned from those who have been investigating this subject, and from the observations of others equally interested.

Dr. H. A. Tomlinson of St. Peter State Hospital, Minnesota, reported, in a monograph, in 1899, a study of 450 female cases. Half of these had some menstrual irregularities. Of the married women 58 per cent. had pathologic conditions of the pelvis, mostly dependent on labor. Many of these were operated on—number not stated—with the following general results: More or less improvement of physical condition, occasionally slight improvement of mental condition, but in the majority of cases practically no effect on the mental condition, and no cases cured. Another series of 231 unselected cases contained 38 whose mental disturbance was apparently increased by the pelvic condition. Seventy presented pelvic diseases justifying operation. Results: Pelvic condition cured in 22, improved in 48; mental condition, no cures, 29 improved, 51 unimproved.

Dr. R. M. Bucke, Ontario Asylum, reports that 136 selected cases—out of 750—showed 126 with pelvic disease; of these 110 were operated on, 196 operations being made altogether. General results: 3 deaths; 40 recovered mentally, 36 per cent; 32 improved, 29 per cent.; 35 unimproved, 32 per cent. The results in inflammatory were much better than in non-inflammatory conditions. Of the cases benefited by operation, the number where duration of insanity exceeded two years equaled the number under two years' duration. Thirty-two non-gynecologic operations showed no mental recoveries. This author places importance on the toxic effect of internal secretions of the ovaries and glandular structures of the cervix, and claims that one-fourth to one-sixth of all female patients in asylums are there because of pelvic diseases.

Dr. A. B. Howard, of the Cleveland State Hospital, reports 12 cases operated on. Results: 1 cured—acute case of 9 months' standing—6 improved—in 3 the improvement was of short duration—4 unimproved; 1 death from malignant disease. Of our own cases, 10 operated on at the Columbus State Hospital showed no recoveries, and in 2 the operation resulted in making the mental condition worse. Another group of 4 cases of ovariotomy was under my observation while acting as assistant in the Cleveland State Hospital, about twelve years since. Results: 1 recovery, 2 improved, 1 unimproved. These cases were 2 of hystero-epilepsy, 1 improved, 1 unimproved; 1 of recurrent mania, improved, has since had one recurrence; and 1 of hysteromania of five years' duration, resulting in a perfect cure.

1. The 206 cases mentioned here as operated on have been gathered out of an aggregate of 2000 insane females.

2. Of the selected cases it appears that we may expect recoveries in about 33 per cent.

3. Of the unselected cases we may expect a cure in about 5 per cent.

4. Inflammatory pelvic diseases promise the best results.

5. The cases wherein the mental disturbances are associated with the catamenia offer the best probable results.

6. Operation on the hereditary, predisposed cases, with no local disease, will most probably result in failure, and leave the patient in a worse condition than before operation by hastening an early climacteric period.

7. The class of cases predominating in different localities differs to such an extent as to probably account for some of the lack of uniformity of results noted by widely separated observers.

After an inventory of the data at hand, it appears that we are justified in the conclusion that pelvic diseases are a factor in the cause, and that surgery is a factor in the cure, of the insane condition. The question now confronting us is what estimate may be placed upon them as factors; as such both evidently have their limitations. The established law of multiplicity and complexity of cause admits few exceptions in singleness of cause. It is important to take the broadest view in the consideration of etiology in insanity. The specialist is too prone to infer the organ of his specialty to be the source of all other pathologic conditions in the body, when the lesion and the remote symptoms may be but consequential to general conditions. In the consideration of cause in the insanity of females, hereditary predisposition, puberty, the puerperal and the climacteric periods are especially to be borne in mind. In the general physical examination, pelvic disease should always be sought for, and when found to exist should be eradicated. No physician should consent to the commitment of a female until the existing pelvic disease is removed, except under absolute necessity from her mental condition. Upon entrance into an asylum, every female should be examined by a conscientious specialist, and if found diseased, operation should be urged. In brief, the rule of practice should be to give the insane woman the same advantages of treatment as the sane, when disease actually exists.

In the absence of pelvic disease, operative procedure as a possible curative factor should be approached with the best judgment and the greatest caution. It is questionable if medical knowledge and experience would justify operating on the defective classes, females at puberty, idiopathic epileptics and those whose insanity is of not over two years' duration. All our asylums have representatives from these classes, who have not only been not benefited, but in reality have been made worse by operation. This is the list it would be at least instructive to parallel with that of the cases benefited, before passing judgment on any case to be operated on.

There are patients who, I believe, may be regarded as non-diseased but operable. These include the hysterical, those especially disturbed at the catamenia, and those in the post-climacteric years. From the first two, some of our most brilliant recoveries have come by the employment of surgery alone. Operation in the post-climacteric period may hasten senility, but is not likely to do much absolute harm.

Discussion on Papers of Drs. Noble, Marcy, Johnstone, Beahan, Ricketts, Tomlinson, Carpenter and Hughes.

[Dr. C. H. Hughes' paper on "Interrelation of Gynecology and Neurology in Practice" was printed in the *Alienist and Neurologist*, of July, and an abstract thereof in The Journal, vol. xxxv, p. 257.]

Dr. W. E. Porter, New York City—The most interesting and instructive fact which has been demonstrated by these highly interesting papers is that we must not, as gynecologists, attempt to deal with this most important subject alone. We must combine with the neurologists, but how infrequently this is done. We have a case presenting these nervous phenomena and we proceed at once to operate, without consulting the neurologist, and unfortunately do more harm than good. The patient is put into a mental state far worse than that which existed prior to the operation. This phase of the subject has not been dwelt upon and I will take the liberty to refer to nervous phenomena as the result of a premature menopause brought on by oöphorectomy and similar operations. In my clinic in St. Vincent's Hospital I frequently have such cases brought to me. Hysteria, mania and hystero-epilepsy occur in a surprisingly large number of cases. The patient has convulsions, epileptiform in character, occurring two or three times a month. I am sure we have all seen many of these cases. The ordinary nervous conditions are most commonly observed. Hence, before proceeding to operate on cases having a history of some nervous condition, we should consult with a neurologist and work with him. There should be in connection with the asylums for the insane a consulting gynecologist. The superintendent can not make a local examination, which every patient should have, and the gynecologist would, therefore, be a most valuable addition to the staff of the asylum.

Dr. George Erety Shoemaker, Philadelphia—It seems to me that Dr. Hughes struck the point at issue, that the gynecologist and neurologist should have the same view-point from the one central standpoint of truth. If we could all have the same training, and look at these things from the same point of view, our problems would be easily solved. Even as it is, our objects and methods are nearer alike than some think. A friend of mine has charge of a large institution for the insane, and is opposed to the gynecologic treatment of the insane. Now, he says that many of his patients show defective nutrition and he always proceeds to build them up. He says he cures quite a number of insane in this way and improves a great many belonging, of course, to certain types. The gynecologist goes to work on cases showing profound nervous symptoms as well as gynecologic symptoms in very much the same way, and proceeds to remove whatever trouble he can detect as an indirect way of improving the patient's nutrition. He has learned from the study of hematology that the presence of a pyosalpinx will alter the proportion of red and white corpuscles and other constituents of the blood. The soreness present prevents all healthful exercise. He removes the infected tubes, not to cure a nervous condition directly, but to put that patient on the highest possible plane of nutrition. He has seen fibroids which have bled a little for years and years and finally the nutrition of the patients is brought to such a low point that disorders to which they may be liable have an opportunity to develop. Given a nervous system unstable by heredity, a bleeding fibroid may thus be an indirect cause of certain disorders of the nervous system. The gynecologist removes the bleeding fibroid, not to cure the insanity or neurasthenia directly, but to help the patient to a better state of general nutrition, and in some instances the result is remarkably good. He finds another patient who gets up ten or twenty times during the night to urinate because of descent of the bladder. The loss of rest has told sadly upon her nervous condition. He restores the pelvic floor and makes the patient comfortable. She rests well and regains her normal nervous equilibrium. We are, many of us, working to secure the same ends, and why need we clash in our theories?

I want to call the attention of our neurological co-workers to a misleading statement which sometimes appears in their statistics or case reports. The statement is "that such and such patients have had their ovaries or uteri removed to cure insanity, etc., without effect." Now, by what authority can they state that those ovaries were removed *to cure insanity?* How do they know whether or not there was grave ovarian disease in those organs? For example, a patient of mine had hysterectomy for large bleeding infiltrating adenoma, practically adenocarcinoma. She was of bad heredity, afterward became insane, and is now in an asylum. I submit that the superintendent of that institution, who has never communicated with me, gravely errs when he classes that patient with others whom he supposes have been operated on for insanity.

Dr. Joseph Eastman, Indianapolis—If there is one thing more important than another, any two things more appalling than any other two, it is the rapid increase of insanity and cancer. If there are more important problems for the coming century I would like to know what they are. Physical deterioration is the law of advancing civilization. The nervous tension so much in evidence in our school system and in society surely stands in a causative relation to the two dire maladies I have mentioned. A young gentleman, the other day, asked for the privilege of serving an apprenticeship with me in order to learn my specialty. I asked him how long he had practiced. He answered, eight years. I told him he had better go back and do general work two years more, as ten years in general work was an essential prerequisite before beginning a specialty. From the remarks this afternoon it looks as though the old-time general practitioner, who looked through the patient's entire system as well as through the speculum, was again coming into vogue. To plough deep, however, implies no attempt to turn a wide furrow. So it seems to me that a series of specialists, ploughing deeply along their respective lines, are needed in these obscure cases and will get good results. I recall two instances where gentlemen relieved insanity by neurologic and gynecologic treatment combined. I have said enough. It was only my desire to pay respect to the subject, which prompted me to take the floor. It were like adding color to the beauty of the rose with a paint brush, or embellishing the beautiful tint of the lily with a pencil to attempt to add one word to the subject under discussion after the scholarly, elaborate, eloquent and beautiful remarks of America's most distinguished neurologist, Dr. Hughes, of St. Louis.

One point with reference to Dr. Rickett's paper, I would like to call his attention to the report of the Edinburgh committee, that calomel beyond a question diminished the flow of bile. What seemed to be an increase of bile was in reality the subsulphid of mercury.

Dr. I. S. Stone, Washington, D. C.—I am reminded this afternoon of a discussion some years ago along the same line, when several papers were read on this very subject. I wrote to nearly every insane asylum in the United States to ascertain whether any examinations of the genital organs were made, and I was astonished to learn that in not a single institution in this country were these examinations made. I want those gentlemen of the asylums—the alienists— to at least give us credit for stirring them up in that matter.

In regard to Dr. Noble's paper, I see he has gone to much trouble and has done a great deal of work. He tells me that he has not read some of the most valuable parts of his paper. Regarding Dr. Rickett's paper, I do not see why he claims that reflex nervous disturbances are peculiar only to gallstones. I am very willing to admit that reflex phenomena do occur. I have operated in such cases, and produced a cure. Adhesions may have some influence on the nervous system, but at the same time it seems to me that an irritation of the foot or any part of the body would have much to do with autosuggestion and influence on the mind. I operated on a case for lacerated cervix, and the patient went insane. She thought her ovaries were removed. I had closed the uterus so tightly that she could not menstruate, and there was a collection of blood. She and her friends consequently believed that her ovaries had been removed because she did not menstruate. She was insane for about three months, when she was operated on again, the uterus was opened, menstruation reappeared and she recovered. I believe many cases of this kind occur.

Dr. D. Benjamin, Camden, N. J.—I have found by examination and observation that a great many ovaries are being removed for pain. The discussion this afternoon, showing the relation of neurology to gynecology, has brought to my mind the fact that when I was assistant in the neurological clinic of the University of Pennsylvania Hospital, we often had patients with severe pain over the eyes, sometimes between the ribs, sometimes in the liver, but that did not mean that we were going to remove those parts. On the contrary, we endeavored to cure the pain by medicines and hygienic measures. Then, when I got into the gynecological clinic, and afterward had charge of an hospital, as I have now, I found that many of these pains were of the same character. We are too liable to forget that factor, especially when a patient comes in as a gynecological case. Many times women will come in and say that they have no pain; sometimes they are run down generally, and sometimes there is a local irritation. I have found that usually the operator proceeds at once to attempt a cure of the local condition, but the same symptoms are present after the operation, either there or elsewhere. I invariably prescribe for patients who are complaining of these pains, without any clear indication of organic disease or the exact locality of a lesion, those medicines which we use in the neurological cases. My assistants have repeatedly remarked about my exclusive use of medicines in many of that class of cases, but the results have justified my doing so. If we will remember to give those patients a full course of antimalarial or antineuralgic and electrical treatment, we will be able to cure many cases without an operation.

Dr. E. G. Zinke, Cincinnati—What a wonderful difference between the meeting of to-day and that of two years ago at Denver. It shows what progress has been made within two years. Two years ago it was war and to-day it is peace. I have been very much instructed and have profited considerably by what I have heard this afternoon, and I wish to contribute my share of the compliments due to Dr. Hughes for presenting this matter in the proper light. No operation should be performed unless there is disease, and no woman should be confined to the insane asylum unless she has been examined by a gynecologist.

I wish to speak of two cases in which, within the last two years, I was called on to operate for pus-tubes. One patient was one of the most charming women I ever met. The result was all one could desire; there was perfect union and the lady left the hospital as well as any one possibly could do. Within one week thereafter symptoms of insanity developed and she had to be sent to the insane asylum, where she was confined for many months; nearly two years passed before she recovered. I was condemned by her family and friends and by many of my fellow practitioners for operating on this patient. Two months afterward I was called to see a similar case. I advised removal of both tubes, and ovaries, too, if necessary, notwithstanding my experience in the other case. Some one hearing of this went to the family and asked them who advised the operation. They were then urged not to submit to the opera-

by doing a trachelorrhaphy. I do not think any man ever did that. I do not doubt his veracity, but I doubt his judgment. While most of us here to-day are exclusively surgeons, yet we are sufficiently versed in medicine to know that salicylate of soda is not the only remedy for rheumatism. Free purgation, rest in bed, warmth applied to the affected part, and restricted diet are well-recognized methods of treatment for this disease. Nearly all patent medicines for the cure of rheumatism contain violent purges. It is probable that Dr. Johnstone prepared his case for operation with a free purge, that after operation she was confined to bed for a number of days, and kept on a restricted diet. It seems to me that it is more reasonable to attribute the cure of the rheumatism to these measures than to the uniting of a lacerated cervix.

Dr. C. H. Hughes (closing the discussion)—The one very important point that has been broached is the question of promising too much. That, I think, is the trouble with gynecology and sometimes with neurology. I have always endeavored to guard against this whenever I advise an operation, as I have often had the opportunity to do. I have never made the mistake of saying that the operation would certainly cure. Another great difficulty in both departments of medicine, especially in surgery, is the amateur, the gentleman who comes straight from college and practices gynecology. We often have to encounter him and his self-confident counsel.

It was stated here to-day that gynecological procedures would cure insanity. It is always a mistake to say that any procedure will cure insanity. Neurology and psychiatry look upon insanity as the product of one or more generations of disease. They consider the neuropathic factor as the predisposing cause. Heredity is another factor. Neurologists all acknowledge that disease of the uterus and its adnexa, or any transmitted irritation, may act as an exciting cause if long enough continued. We then have insanity connected with uterine trouble. The gynecologist who will tell his patient that she will get well after an operation, is likely to make an error of judgment, although sometimes he may be making a correct statement. My rule in advising people is always the same. I tell them that this thing is a source of irritation, that if I had it I would get rid of it in order to give myself the best chance. I have always been very careful not to commit myself as to the outcome of the trouble. I have seen a trifacial neuralgia which ultimately recovered by persistent treatment, and yet after the patient had recovered I was surprised to find mental aberration set in. I had to treat her for two months before she began to recover. She had been gynecologically treated some years before that and the people blamed the gynecologist for the insanity.

Dr. E. C. Carpenter (closing the discussion)—My position with regard to giving the insane woman the same chance as the sane I still hold as tenable, because I regard the mental part of the disease so serious a matter that even where local disease is only a probable element, the patient should have the opportunity of having that cause removed.

Dr. Edwin Ricketts (closing the discussion)—I will admit that Dr. Zinke's criticism that gallstones sometimes recover is correct, but I am quite sure that he would not take the chance on any pus-tube. Nevertheless, we know that some neglected cases of pus-tube empty themselves and recover and yet we do not stop to advocate the removal of pus-tubes. As to Dr. Eastman's remark, I want to call his attention to the fact that there is quite a difference betweeen bile escaping from a fistulous opening and that coming through the anus. That is probably responsible for his sulphid of mercury.

Dr. Henry O. Marcy (closing the discussion)—A consultation took place, more than sixty years ago in London, between Sir Benjamin Brodie and Dr. Thomas Watson, who wrote the most excellent text-books on medicine and therapeutics, the standard works for a generation. The great surgeon, Sir Benjamin, asked the famous physician to first give his opinion. Dr. Watson replied:

"It is good medical practice to remove the cause of irritation, if possible, and then trust that the irritation itself will cease." Therefore you see that we, in this closing period of the century, are not very much wiser than those men of the earlier time. I wish to refer to certain of the points not brought out in regard to Dr. Bucke's report. Quite a number of years ago he and I discussed the relation of nervous and mental diseases as often dependent on pathologic conditions of the reproductive organs. He said: "I will examine the 500 women under my care and ascertain how many, if any, are the subjects of pelvic diseases." The results have been published and he is now the most enthusiastic gynecologist I know. Cured, 40 per cent.; greatly improved, 30 per cent.; making 70 per cent. benefited by operative procedure. I suppose Dr. Bucke would say that he had removed the cause of irritation and therefore the patient recovered. I have asked superintendent after superintendent of the asylums what they knew of the pelvic diseases of the women under their care; the answer has been invariably a negative one. The multiplied testimony of to-day goes on record to show that the gynecologist and neurologist are in a common service, removing causes of irritation, believing that the mechanics of the great human machine, restored to its normal equilibrium, will permit the execution of its normal functions.

THE RELATION OF SURGERY TO DIABETES.*

C. P. GILDERSLEEVE, M.D.
Attending Surgeon to St. Peter's Hospital.
BROOKLYN.

There exists an intimate relation between diabetes and surgery, principally due to the fact that diabetics are prone to gangrene, and this intimacy, in my opinion, is rendered especially dangerous from the fact that its existence is too often carelessly dealt with, and a great many men have failed to appreciate its importance until they have seen a gangrene follow an operation in which there was apparently nothing present to result in any such course, and it certainly seems to me that insufficient importance is attached to this subject. So far as I have been able to learn, not very much has been written and the standard text-books say but very little. Erichsen makes no reference to diabetic gangrene; I quote the following from "The American Text-book of Surgery," and it is practically all it says: "Individuals suffering from diabetes are frequently attacked with gangrene. Operations on these patients are supposed to be frequently followed by gangrene, and it is advised by some authorities to abstain from operating on these cases if possible. A more extended experience with aseptic surgery, however, will probably not sustain these views."

In Dennis' "System of Surgery," the author admits that diabetic patients are liable to suffer from gangrene, and gives as the reason the fact that the tissues in these patients are weak and are probably in a condition favorable to the growth of germs. He states that the mere presence of sugar does not cause gangrene, but claims that it is due to the accompanying arteriosclerosis. The "International Text-book of Surgery," which has just been published, says nothing in addition to the foregoing. Dr. C. Von Norden makes the following statement: "Wounds of the skin, also deeper wounds, heal more slowly in diabetics." Infection gains access more readily, granulations incline to necrosis, and he thinks that former reports of an unfavorable course of wounds in diabetic subjects are due to infection caused by imperfect surgical technique; he claims that with the asepsis and antisepsis of to-day this has been entirely changed, and that the results are now such that no distinction need be made between diabetics and non-diabetics so far as operating is concerned.

---

*Read at the Sixteenth Annual Meeting of the Fifth District Branch of the New York State Medical Association, held in Brooklyn, May 22, 1900.

Dr. Naunyn, in an article on "Diabetes Mellitus," makes the statement that "Septic infection increases the glycosuria, and that in cases of carbuncle, phlegmon, and gangrene the glycosuria at once diminishes and frequently disappears after the abscess has been opened, or the gangrenous member has been removed."

Legroux reports an interesting case. The patient suffered from diabetes insipidus, without a trace of sugar in the urine. He received an injury to the leg, which would not heal, and the wound became gangrenous, and then it was found that the urine contained considerable sugar. This author holds the same views as Von Norden in regard to wounds in diabetics, viz., that with antidiabetic diet and with thorough asepsis and antisepsis the wounds do as well as in non-diabetics; but admits that in fractures the bones in diabetics unite with difficulty. Taking the foregoing as a sample of the literature on the subject, it appears to me that, while there is a direct relation between diabetes and gangrene, the connecting link has not yet been discovered. It is true that these patients often have arteriosclerosis, and other conditions frequently coexist which favor the development of gangrene; still, it is also a fact that gangrene often develops in a case where the only apparent reason therefor is that the patient has diabetes. These are the reasons which in my mind render it advisable to connect diabetes and gangrene in the relation of cause and effect. Two years ago I operated on a patient 58 years of age, for gangrene of the great toe, who also had glycosuria to a marked degree. His general condition was fairly good and he was attending to his work until the condition of his toe forced him to bed. His arteries were moderately atheromatous. In this case I made the mistake of not amputating sufficiently high, as I operated near the proximal end of the metatarsal bone. My object in selecting that point was the fact that experience has taught me to leave the tarsal and carpal joints alone when possible, and in this particular case the foot outside of this toe was apparently in good condition. But whether I was too conservative or not, the fact remains that gangrene promptly set in, and I lost no time in advising an amputation just below the knee, to which the patient readily assented. Anticipating sloughing, I left the flaps long, and the wound open. Gangrene developed in the flaps and they sloughed away, leaving the bone slightly exposed. Finally the wound began to granulate, and I distinctly remember that the healing process went on much more rapidly under the influence of hot charcoal poultices. These I first applied to hasten the slough, and after that I tried nearly everything, such as aristol, iodoform, balsam peru, etc., but nothing stimulated the granulations as these poultices. Since then I have often found that in indolent granulating wounds this treatment gives good satisfaction. This patient to-day is wearing an artificial limb and his general condition is fairly good.

About one year ago, I had a case of phimosis occurring in a man 50 years of age; the foreskin was tight and indurated. I circumcised him and gangrene promptly developed at the seat of the operation; a circumscribed spot also developed on the scrotum, which rapidly spread and caused his death in a few days. This man's arteries were in fairly good condition; his general condition was not good; his urine was loaded with sugar and he claimed to have had diabetes several years. Still he was not confined to his house, but was out most of the time. This is one of the cases which causes me to believe that there is some obscure but certain reason why gangrene so often develops in these cases. Another peculiarity in these patients is the effect which an operation has on them, so far as their glycosuria is concerned, which is not uniform. In the majority of cases the amount of sugar in the urine diminishes as it did in the first case I mentioned, but in other cases the glycosuria increases after an operation, and these patients often die with diabetic coma.

I remember a case in which I amputated in the middle of the forearm for gangrene of the hand occurring in a case of diabetes. The patient was a woman of 45 years of age, and the first suspicion that she had diabetes was when I examined her urine, and she had previously been seen by two medical gentlemen who had simply diagnosed "gangrene of the hand," and without any hesitation advised amputation. Her arteries were in good condition, and certainly not in a condition which would warrant one in attributing the gangrene to any disease of the vessels. After the operation the glycosuria increased and she promptly died, with diabetic coma. This may have been a coincidence; her death by diabetic coma may have been due at that time, and the fact that she had been subjected to an operation may have had no bearing on the result, but I believe that the condition was brought about, at least that it was hastened, by the operation.

The symptoms and signs of diabetic gangrene are so generally well known that it is not necessary to dwell upon them, but the question naturally arises: what shall we do in these cases? Here, as elsewhere, we have to be governed by circumstances, but there are a few rules which I believe it well to follow, and I base them upon the belief that, regardless of asepsis, antisepsis, antidiabetic diet or anything else, there exists a tendency in diabetic patients toward gangrene. Diabetics are not favorable subjects for anesthesia; and the number of cases that have been reported in which the glycosuria was increased after an operation, and several cases in which death resulted from diabetic coma, cause me to feel that we should always make a broad distinction, so far as operating is concerned, between diabetic and non-diabetic subjects. I make it a practice to observe the following rules:

1. I would not operate on any patient suffering from diabetes without first explaining either to the patient or some one in authority the possibilities which might follow.

2. I would refuse to operate on an elderly diabetic subject for any of the simple affections, such as benign tumors, etc., unless there was some special reason for operating, and it is certainly a good rule to always examine the urine in any case of gangrene occurring in elderly people.

3. In the painful, rapidly-spreading gangrene which often occurs in these cases, and which is bound to cause their death if left alone, I believe in prompt and high amputation. As a rule, I wait until a line of demarcation forms; but in some cases, although the line has not formed, one can judge fairly well about how high it is going by the appearance, and in such a case I would operate before the line had actually formed. Some of these cases are inoperable; they may have complete gangrene of the foot, and the leg may be in good condition. Again, the leg may be indurated and boggy, and this condition may extend as high as the knee or above it, and it would be poor judgment to operate on such a case. Another class of cases is the dry, comparatively painless gangrene which often affects the toes in these patients. These cases will often run their course and be cast off,

and as a rule they should be left alone, so far as operations are concerned.

Furuncles and carbuncles frequently occur in diabetic patients. The furuncles will usually succumb to the general treatment for diabetes. In the case of carbuncles, however, surgical treatment such as hot applications and the knife at the proper time are required.

FRACTURE OF THE SUPERIOR MAXILLA IN A MAN 70 YEARS OLD, WITH RECOVERY.*

VIDA A. LATHAM, M.D., D.D.S., F.R.M.S.,
ROGERS PARK, ILL.

The subject of fractures of the superior maxilla must always be of interest to some of the profession. As a general rule, perhaps the injury comes first to the general surgeon, who may or may not call in a skilled dentist to assist him. In many instances, I am afraid a general practitioner is not as well informed in the treatment as he should be from a dental standpoint, and it is not to be wondered at when we consult our text-books or journals of surgery on the subject—the information being exceedingly meager and ancient. It may again be asked: Is the dental surgeon, unless doubly qualified,[1] capable of taking entire charge of such cases, especially as the injury is usually severe and may have complications, as shock, hemorrhage, meningitis and septicemia? The position of a dentist has recently been decided in at least one of the states by the courts. The court maintained that by using the title "dental surgeon" or "dentist," he has the right to treat such cases without fear of being judged unqualified or incompetent. By some, the question of not treating the case in consultation with a dentist and surgeon would be considered wrong. It may be asked if our dental schools are wise in not requiring a better course in oral surgery, with operative demonstrations on cadavers, etc., and at least giving a good training, so that a qualified dentist would be able to treat intelligently the usual class of cases belonging to the head and neck, and not consider a "tooth" as the only occupant of a patient's head.

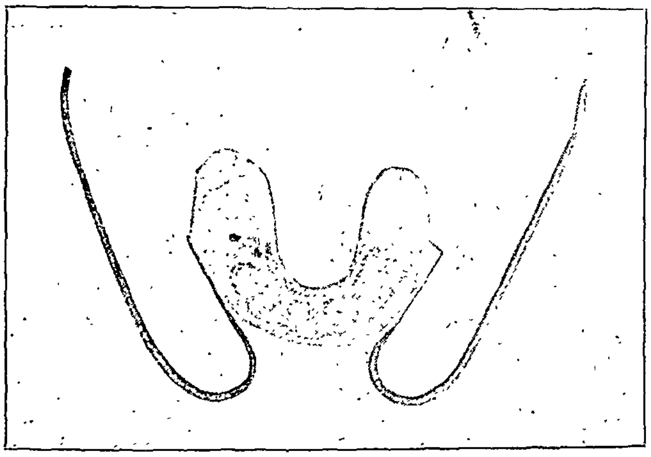

Fig. 1.—Lower Surface of Splint for Mandible to fit in and Holes to Wash Through.

As I previously mentioned, the literature is meager on the subject of such cases. Is it from the rarity of such injuries? Possibly not, for in looking over the reports and bibliography, I soon came to the conclusion that more cases might be found if considerable time could be given, for the classification is so mixed as to make it nearly impossible to avail oneself of those reported. Almost every variety of heading must be looked under, viz., "face, maxillary, maxilla, malar, jaws, crushing injuries, dislocations, nasal bones and surgery." One case I found, by accident, under "Typhoidal Widal Reaction" in the *Index Medicus*. Dr. John S. Marshall, in his work on "Injuries and Surgical Diseases of the Mouth and Jaws," 1897, reported a similar scarcity, finding only 19 cases in the literature within his reach. To these I can add 14 more in the literature I was able to obtain; and one case besides that came under the care of Dr. Bertha E. Bush and myself. I will here give a brief summary of one of the reported cases, to show some of the difficulties in treating it.[2]

J. W., aged 38, injured by the bursting of an emery wheel. Fractures of left malar, nose, and four distinct comminuted fractures of the superior maxilla, two transverse, one in the middle line of mouth and separation of nearly all of the alveoli containing the teeth and a depression of the same of about ½ inch. Seen in a semi-comatose state, in which he remained for hours. Hemorrhage free and shock. On the third day a vulcanite splint was attempted after the manner of the Gunning pattern, patient being etherized for the purpose. The plate had to be removed, as the fragments would not stay well in position at the end of the week. After consideration, ether was again given on the tenth day and the bones drilled, silver wire being used to coaptate the bones; a roller bandage and chin support were used. Liquid was given through a tube, and the mouth was washed twice a day with listerin. The wires were removed the fortieth day, the union being perfect. Patient talked and chewed fairly well, but the range of jaw motion was naturally lessened and there was loss of smell and taste.

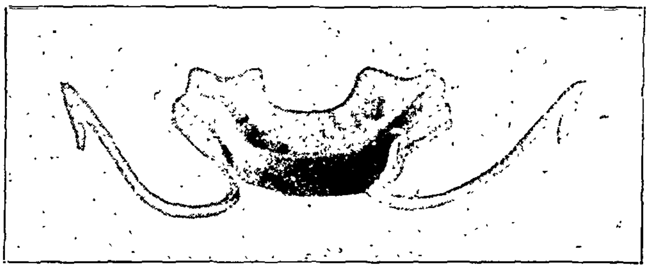

Fig. 2.—Anterior View and Upper Jaw Surface. Marshall Splint.

To the cases already reported I wish to add one recent one which came under my care during the past year. It is as follows:

On Sept. 14, 1899, A. B., aged 71 years, a man of strong physique, good health and habits, received a fall of 25 feet while examining a building. He was standing on a ladder which gave way and went to the ground under him. The patient fell forward, striking his face on one of the rounds of the ladder, nearly transversely at the level of the end of the nose, and also sustaining numerous bruises about the neck and shoulders and a sprain of the left wrist. He walked unaided into a house near by, and though considerably shocked was at no time unconscious. The immediate hemorrhage was very profuse from nose and mouth and continued about one hour. Dr. F. Keefer, who examined the face before much swelling had occurred, and Dr. Bertha E. Bush, of Chicago, found the upper alveolar margin and teeth freely movable en masse up and down as if upon a plate, though the mucous membrane of the mouth was intact except at the upper lip. The nasal and malar bones seemed uninjured and there was no orbital hemorrhage. The vomer, palate and inferior turbinated bones were comminuted, crepitus about the alæ and septum of the nose resembling the "crackling feel of a broken eggshell." During the copious antiseptic irrigations of the nose and mouth, which were repeated every three or four hours in the first few days, the solution could be made to flow with some difficulty from either nostril into the mouth, but clots of blood and mucus, together with the extreme degrees of swelling which promptly ensued, effectually prevented nasal respiration. Deglutition and speech were difficult at first, but never quite impossible. The patient rallied somewhat slowly from the shock, and during the reaction developed a temperature of 101 F., which, however, subsided in less than a week. For twelve days after the accident no retentive appliance was adjusted, the treatment being directed solely to sustaining the patient's strength, relieving pain and keeping the injured parts as clean as possible by sprays, douches and gargles of antiseptic solutions and by wet compresses, principally borolyptol compounds and boracic acid. By this time, swelling had much diminished, there was only slight oozing of blood into the nose and pharynx, and a degree of hardening was perceptible about the floor and walls of the nares and the roof of the mouth. The soft parts were in good condition and no necrosis of bone had occurred. The mouth was habitually open for respiration, although the patient could at times breathe through his left nostril with effort. The face was markedly lengthened in the region of the injury, that is, the nose appeared longer than normal and a little flattened, and the distance from the angles of the mouth to the eyes greater than before. The upper lip was longer (vertically), especially when the mouth was closed. The upper incisors dropped behind the lower on closing the jaws, a condition not usual to the patient previously.

*Presented to the Section on Stomatology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Possessing a medical and dental qualification.

[2] Staples, A. F.: Railway Surgeon. Chicago, 1898-9, pp. 133-135.

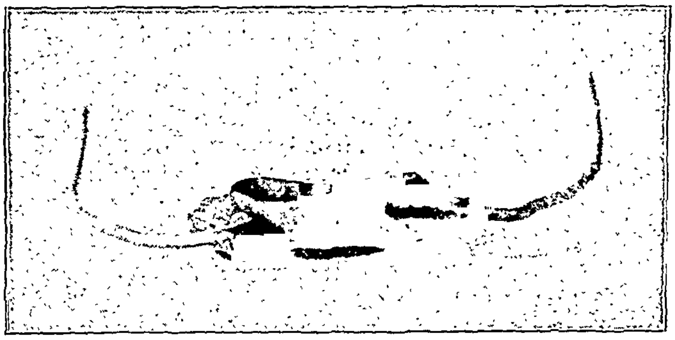

Fig. 3.—Marshall Splint. Anterior View. Slides for Wires.

None of the teeth had been loosened within the alveoli, but the entire row of upper teeth with the anterior portions of the superior maxilla moved freely up and down more than a quarter of an inch, a little lateral movement being also apparent. Pressure on either side of the nose beneath the orbits during the vertical and lateral movements of the upper jaw showed motion of the bony parts at those points, proving that the fracture of the superior maxilla had been far above the alveolar border; that separation from some of their upper articulations was probable. Ten days after the receipt of the injury the patient was brought, by my advice, to Chicago, a distance of 100 miles. He was seen, in consultation with us, by Dr. John S. Marshall, who directed the further treatment. It appeared certain that bony union of the fractured maxilla could not take place unless the fragments were held continuously in position, the anterior separation being fully a quarter of an inch when the mouth was open. Support was not to be derived from any splint or bandage under the lower jaw, owing to the obstructed respiration when the mouth was closed. It was therefore determined to retain the loosened fragment in position by an interdental splint supported from the vertex, after the method described by Dr. J. S. Marshall, in his work on "Injuries and Surgical Diseases of the Face, Mouth and Jaws." On Sept. 24, 1899, the models were taken in modeling compound, and the following day a rubber plate was made to fit over the upper teeth, with spaces into which the lower teeth might close accurately. On each side of the plate a grooved piece of metal was imbedded and into each groove a wire spring was slid from before backward, the wire being bent on itself so that its shorter end occupied the groove in the plate and the longer end extended back four or five inches with its tips bent down. These two wires were easily slipped into place, after the plate was adjusted in the mouth, the wires passing out of the mouth opposite the cuspid teeth. A cap of netting and leather was made, with properly placed loops and buckles for adjusting the straps fastened to the wire springs. (See Figs. 1 and 3.) The apparatus was applied September 26, on the twelfth day after the accident and was worn day and night for three weeks, after which it was removed at night and worn in the day time for another week—Fig. 4. On removal of the support, union was found to be firm with only slight deformity, viz., a lengthening of the middle portion of the face. The patient could eat solid food, breathe with the mouth closed and complained of no pain except a numbness of the roof of his mouth and slight impairment of the senses of smell and taste—which is still present, eight months later. He gained in weight and strength and was able to work.

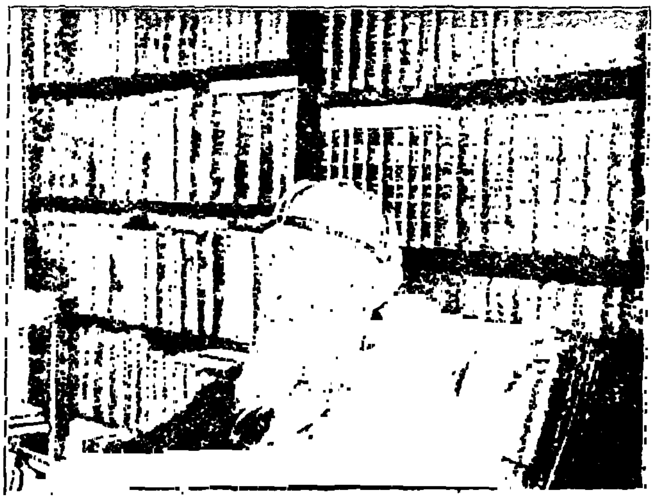

Fig. 4.—Fracture of Superior Maxilla and Vomer Bone, etc. Marshall Splint.

There are certain points in this case which are of interest to the general as well as to the dental surgeon:

1. The disadvantage of trying to use bandages, occipitofrontal and occipitomental, and the discomfort of a chin bandage.

2. The difficulty of respiration and danger of malocclusion, which latter must never be lost sight of and every effort made to secure perfect or as nearly perfect occlusion as possible.

3. The lack of perfect support to the jaw if wired only, and the need in many instances of an anesthetic for the same.

4. The guide which the interdental splint gives to

the mandible for correct occlusion, and hence chance to note any dropping or displacement of the splint.

5. The disadvantages of the plate are so few that they may be easily remedied, on account of its adaptability, and they differ with the patient's disposition: 1, the feeling of tightness around the head, which may give headache if not adjusted; 2, the slipping of the side tapes until the balancing point was found, can be remedied by making a downward curve (Fig. 5), bend or points in the wire, as seen in the diagrams.

6. The cap must be a good and accurate fit, the vertex leather not coming too low down to the ears.

7. The advantages of lightness, air through the mesh over the hair, use of non-corroding metal for the bars and sockets, or nickel-plating, the ease with which the plate may be slipped out and cleaned while the douching and irrigation is being done.

8. The advantage of drilling several holes in the sides and through the alveolar part of the plate so that syringing with water and antiseptics can be done, when the plate is put in, to get rid of particles of food.

9. The greater variety of solid food that the patient can eat, as it can be crushed by the tongue against the plate.

10. The bilateral, almost symmetric injury, giving no point of support within the oral cavity, yet resulting in very slight alteration of the face after recovery.

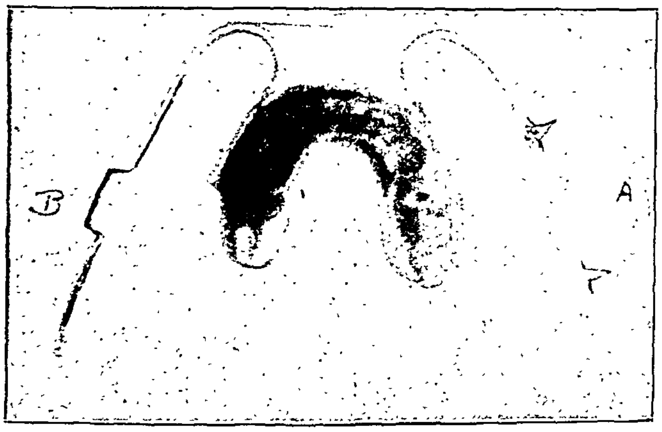

Fig. 5.—A.—Diagram of Points to Prevent Tapes Slipping. B.—Diagram of Bend.

11. This form of splint, a modification of Kingsley's, has this advantage over others, it can be vulcanized in an ordinary flask and the metal bars slipped in after the plate is polished.

12. Lastly the age of the man, being the oldest recorded case of recovery in the literature at my command.

THE PHYSIOLOGIC TRAINING OF THE FEEBLE-MINDED.*

SAMUEL J. FORT, M.D.
ELLICOTT CITY, MD.

American institutions for the care and training of the feeble-minded are the results of a little more than a half-century of the work begun abroad by various observers in a semi-scientific manner, it being reserved for the elder Seguin, a student of Itard and Esquirol—the French pioneer workers—to formulate a system from dilettantism. The year 1848 saw the beginning in this country of Seguin's enthusiastic, brilliant work, inspiring American workers—a beginning that places Wilbur, Brown, Knight, Kerlin and Richards almost side by side with Seguin; that saw two institutions in as many states multiplied in 1900 to 19 state and 10 private institutions, caring for a total of nearly 8000 feeble-minded persons. It is true that Seguin's methods of training the feeble-minded are yet considered the best, being founded on the only true method of all teaching—the physiologic—the only system that takes cognizance of the individual and the only system that prevents both student and teacher from becoming mere machines. Seguin died before he saw more than the beginning, in this land of his adoption, of a work for which he practically gave his life, but he left behind him a valuable legacy in the hands of brainy men, quite as enthusiastic as himself, and while the so-called physiologic system of training the feeble-minded still stands an enduring monument to a talented man, American talent has widened and extended the scope of the system far beyond the anticipations of its inventor.

Primarily, observers of the mentally deficient worked purely from philanthropic motives; later, from the standpoint that many such individuals were simply isolated from normal men by deprivation of proper training, and still later Seguin defined idiocy and apparently recognized somewhat indistinctly several types that differed from actual idiocy, types now definitely classified—thus:

1. Imbecile....	Mentally deficient Mentally and morally deficient..	High grade.. Middle grade.. Low grade..	Educable.
2. Idio-imbecile..........			
3. Idiot..........			Non-educable.

It is unfortunate that we have not yet as a people recognized the anatomic deficiencies of our feeble-minded charges as being of paramount importance in prognosis. Fostered by ignorant persons, interested only in securing large fees for impossible though promised results, advertised by yellow journalism, the idea of *cure* is yet prominent, notwithstanding the absolute fact that we have in all cases an inherent deficiency, beyond the reach of surgery or medicine to restore. Whatever share of active nerve-center is present may perhaps be acted on, but if a normal standard is a whole, no fractional part can ever be equal to the whole. This to-day stands like a wall barring the progress of our work as a factor in the system of public education.

---

*Presented to the Section on Diseases of Children, in a Symposium on The Feeble-Minded and Nervous Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Even the marvelous attainments of individuals like Blind Tom are urged as reasons why imbeciles may be trained so that may eventually become members of the body politic, forgetting that while one or more protrusive talents have raised the individual not only above his more ordinary brothers and sisters in affliction, or even above the average normal man or woman, there still remains the heritage of physical weakness and mental inertia in all save the one development, rendering them incapable of taking their place in the active busy world, handicapping them too heavily in the race for existence, making them useless outside of the fostering care of an institution.

The mere thought of restriction is so repugnant to many that the value of environment is lost to sight. Yet to the defective child of whatever grade of mentality, whether well-to-do, rich or poor, the home environment is as a rule bad. Whether *ego*, in so many cases rampant, is stimulated to an unhealthy growth by too much care, or on the other hand if the child's little meed of mind is crushed out by deprivation of its poor little wants, the results are the same, retrogression and mental apathy. No class of children responds more quickly to the community interests of the institution than the feeble-minded. Many may at first be homesick, but the orderly life, companionship of similar mental attainments, oversight by judicious foster-mothers, the music, the flowers, soon overcome the nostalgia and the warped and twisted human plant soon begins to grow and become more like the standard set by its trainers.

The physiologic system as formulated by Seguin contemplates the use of the hand, the eye and the ear as the avenues of entrance into the undeveloped mind, and demands an early recognition of the condition for its best results. The feeble-minded child as a rule is a creature of habit, and these habits are distorted from the normal by reason of the deficient or defective co-ordinate powers. Experience has proved the difficulty of overcoming the automatic or mechanical habits even in the young and of short standing, hence the advantage of placing the erring centers and muscles under regular systematic training at an early period in life.

The kindergarten has proved of great importance not only in the training of the young subnormal, but in the diagnosis of the youthful defective. The trained kindergartener can hardly fail in recognizing both moral and mental deficiencies in her classes from the very nature of the methods employed.

Nature studies and object-lessons follow in natural sequence, then sloyd and manual training, all aiding in mental stimulus and muscular activity. The underlying principle of our present system is to develop, by every available method, the ability to think and to do. If the state is to assume life-care of its feeble-minded population, it must endeavor to develop as many earners as possible. The asylum will contain the drones, those incompetents who will always be in debt for their existence; the training-school and the colony must return to the state as much of their cost as possible, and this can be done only by systematic application of intelligent exercises, devised to stimulate a desire to do something that may be of use to others. This carries the boy or girl through the kindergarten and the class-room into the shops; those unable to keep along with others, reaching their limit of attainment, may still find room for employment in the more simple work of the farm, the garden or other duties needing a minimum of mental exertion, but still giving enough muscular work to prevent retrogression.

The ever widening horizon of this physiologic training has each year taken in every modern development of educational facilities. Of these, manual training as now seen in our numerous polytechnic institutions is one of the most important systems yet devised, and while yet in its infancy as an adjunct to our institutions for the feeble-minded, is each year assuming greater proportions. In its application to normal children, it proves an important agent in detecting mental and physical defects; in its application to the subnormal child, it is equally important in counteracting these defects. A writer has said: "What orthopedic surgery is to the body, such, I believe, manual training in childhood is to the mind." Twenty years of work among the feeble-minded leads me to think we have only seen the beginning of what the future will see of the results from manual training in our institutions.

It is even now a question of serious importance whether we have not paid too much attention to mere school training. If we are to assume the life-care of the feeble-minded, the question of an individual ability to earn all or a part of his or her support must be carefully considered and in this relation mental cramming can not be considered a factor in the ability to earn. Certainly there are at least those of one class, the moral imbeciles, even if their environment is to be permanently restrictive, that should not be too highly educated in the sense of knowledge imparted. Many of this class stand on the border-line of insanity and I am certain that to some might be said that which was said to St. Paul: "Much learning hath made thee mad."

It is not intended to make persons afflicted mentally prisoners for life at hard labor. Such are taught to work because it is wrong to be idle, and in the colony of defectives, free from the ever-present problem of whence their daily bread shall come, the grim specter of the self-dependent workman, they can labor through work hours, and be in position to enjoy the recreations and amusements provided under the same schedule that calls them to work.

Now, if this system of physiologic training is correct, and there seems to be no reason to doubt its efficiency, what can be urged for the future, judging by the results of the past?

1. The state owes its mental defectives proper care and training, and a proper consideration of the normal and subnormal demands life-guardianship of those unable to support themselves in the outside world and a bond on the part of the well-to-do that provision shall be made for the support of their feeble-minded progeny.

2. The enormous increase in the number of this class of incompetents urges a closer attention to the proper enumeration of all such defectives in each state, their registration on the files of state boards of health, and penalizing both parties to a marriage contract, in which one is known to be feeble-minded.

The question of asexualizing both sexes of the feeble-minded has been considered, but the proposition that contemplates such surgical procedure where no pathologic condition exists beyond the mental deficiency is too extreme to be practical. Granting that the female is the only sex to be considered, the radical obliteration of her ability to procreate other imbeciles seems to me to argue our inability to properly care for her. And if we produce such a condition, simply to relieve ourselves of the protection she deserves, we are licensing an evil condition, and if her condition was known, throwing a veritable firebrand into the community. Procreation is not the worst evil that can obtain from the contact of sexes where one is weak, the other an unmitigated scoundrel.

3. Experience has proved the value of early recogtion of mental deficiency, and application of proper training, hence the value of expert examination of school children, especially the so-called "incorrigibles," "truants," "juvenile delinquents," et al, and their grouping either in state institutions for the feeble-minded or in special classes under special instructors.

4. Our normal schools should make the study of training backward and mentally deficient children a compulsory and thorough course, that our public school teachers may be better able to co-operate with the medical examiner in detecting signs of mental deficiencies, and thus aid in weeding out the defectives from the ordinary schools.

5. The system of manual training as pursued in our polytechnic schools is one that is advantageously used in our institutions for the feeble-minded, and at least one-third the schedule time of school work might be passed in properly equipped shops with advantage.

6. Purely abstract education should be limited to the highest grades, and where these show signs of moral obliquity, every effort should be made to advance the physical rather than the mental development.

KERATOLYSIS OR "SKIN-SHEDDING."

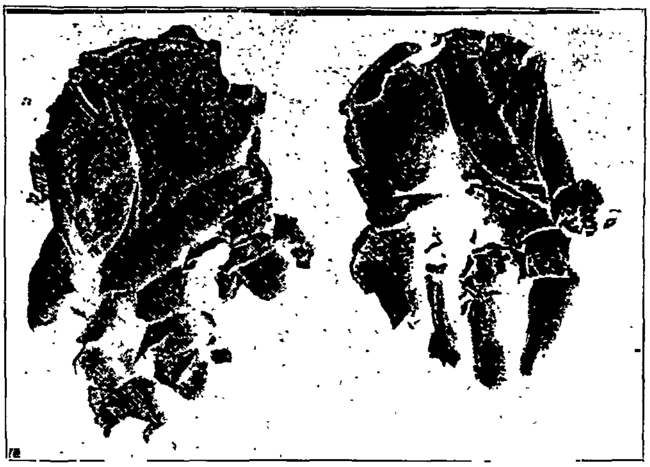
R. M. STONE, M.D.
OMAHA, NEB.

I had the good fortune recently to see one of the rare cases of "skin-shedders." This was a man of 50, strong, hearty, quite intelligent and entertaining in his description of his peculiar condition.

Family History.—He comes of a long-lived race, two of his grandparents having reached over 100 and his father being alive at about 90. He has six living brothers and sisters. No one of his family has ever been known to shed his skin.

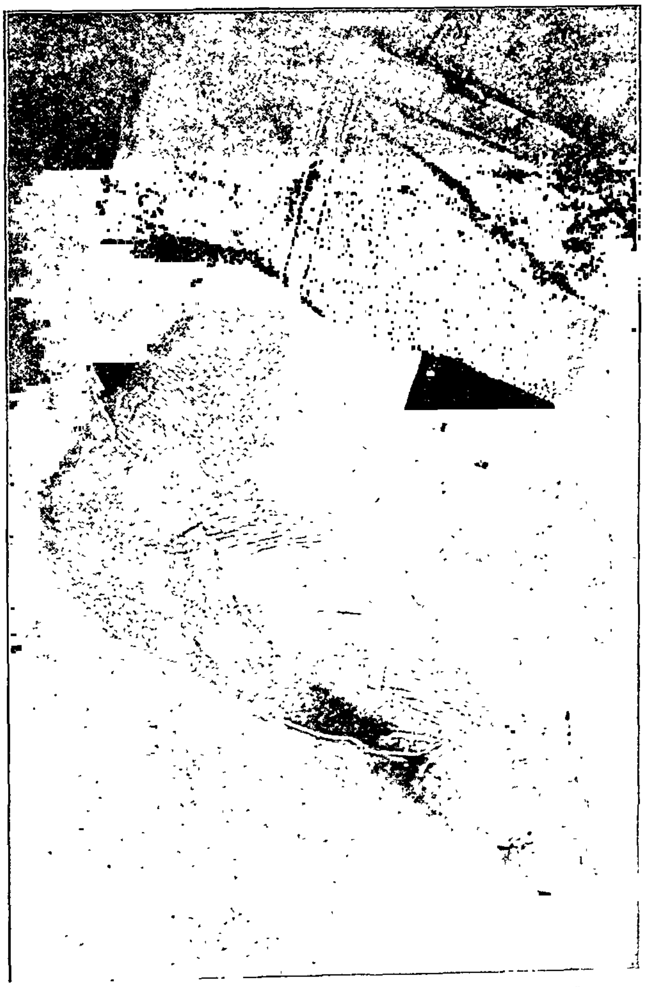
Personal History.—His parents told him that he was born in May, 1849, and that he shed all his skin in the July following, and every year of his childhood. Since he has reached years of ability to remember, he states that he has shed all the skin of his body every summer and, in the years 1893, 1894, 1899 and 1900, has shed it the second time about a month later than the first shedding.

The period of shedding is ushered in by a feeling of malaise and chilliness, followed by fever, which has risen as high as 103 F. The skin of the body generally scales off, while that of the palms, elbows, buttocks, penis and scrotum, the knee-caps and feet comes off in mass. The hair of the head, the eyebrows and his moustache all are lost. He is not rendered bald each year by the loss of hair, but it comes out little by little as it does after typhoid fever. A few times only has there been a shedding of masses of the skin of the legs. The nails of the hands and feet participate in the shedding. The new nail is, as would be expected, more sensitive than any other part of the body, and somewhat slower in renewal. In general, the body is not very sensitive, for he is able to work right through it if he wishes. Forty-eight hours after he has shed he can take a full cold bath without discomfort or danger.



He sometimes wears gloves for a day or two after the shedding.

When the skin begins to shed, the perspiration ceases to pass through to the outside and raises up the epidermis, which dries and becomes somewhat hard before it is cast off. When this is struck with a pencil it gives off a sound as of striking a piece of celluloid.



He spent twelve years in the regular army, and supposes that his case was reported to the surgeon-general.

He has been examined by many physicians, but has never been able to secure any suggestions as to relief from the annoyance. He has never taken any medicine other than a little quinine for the fever present during the process.

To-day he has nearly completed the shedding; this year he has gone through two periods, and has three coats of skin on his body at places. The heels are just about to lose a very heavy layer, and beneath it can be seen a layer less heavy which is peeling, and yet beneath it is a new skin entirely normal.

The case is one of keratolysis, and is described and illustrated best in "Anomalies and Curiosities of Medicine," by Gould and Pyle.

IMPERFECT DEVELOPMENT.

REPORT OF A CASE OF LACK OF DEVELOPMENT OF THE RIGHT SIDE OF HEAD WITH CONGENITAL MICROPHTHALMUS, COLOBOMA IRIDIS, LACK OF EXTERNAL AUDITORY CANAL AND IMPERFECT FORMATION OF AURICLE.

GEO. F. KEIPER, A.M., M.D.
EYE AND EAR SURGEON TO ST. ELIZABETH HOSPITAL, ETC.
LA FAYETTE, IND.

Dr. George K. Throckmorton, of this city, kindly called my attention to the above case about eighteen months ago. At my earliest convenience thereafter the patient was visited and inspected. It is a matter of great regret that no photographs accompany this description. Before the arrangements could be completed for taking the child's photographs it died.

At the time of the visit to Mr. G.'s house we found a seventeen-months child. The right side of the head was about two-thirds that of the left side, the latter being perfectly developed. The right eye was microphthalmic with coloboma of the iris downward. The coloboma was quite large. The eye was apparently blind.

No vestige of the right bony auditory canal could be detected. There was only a slight depression in the temporal bone, and that was covered with skin. Of the auricle, the lobe, tragus, antitragus and inferior portions of the helix and antihelix were wanting. The child had a mouth like a catfish. Both maxillary bones showed a fairly perfect development on the left side, but imperfect on the right side. What teeth the child had were imperfect and had not appeared in the usual order.

The right side of the body showed a lack of development, the arm and leg being markedly smaller than those on the left side. Otherwise the development was normal. The condition as noted in the child is very rare, and on this account is reported.

Concerning absence of the lobule, with absence of the external auditory canal, a case has been reported by Szenes.[1]

American Medical Association Meeting.—There was a notable lack of such experiences as have caused some members to vow that they never would attend a meeting of the Association, if held in a city of less than 200,000 inhabitants, and those who staid away this year on account of such a vow should be told about it. The fact is that the number of permanent inhabitants in a city has very little connection with the extent of its hotel accommodations, and gives very little indication of its capacity for handling a convention. This suggests the question: Is the nominating committee, as at present constituted, the best possible body for investigating the suitableness of a place for a meeting of The American Medical Association? Its members are chosen one day, meet the next, and often complete their labors at a single sitting. They have so many other things to do, that in the absence of better reasons the "I've helped you, now you help me" argument has too much weight. Lacking time to study and think about the question, lected to urge the claims of their respective cities that a wise the committee is so largely at the mercy of the orators sejudgment must be almost impossible. This can all be said this year without seeming invidious, for although other places talked about it, St. Paul was the only city that had nerve enough to come into the committee with a formal invitation for the meeting, and to urge its acceptance. It would at least be wise to expect henceforth, that a city aspiring to this honor should, through The Journal, extend its formal invitation, and explain its abilities to do well what it wished to undertake, as Denver did, several weeks prior to the meeting of The Association. And in the putting forward of its claims, the situation and capacity of its hotels should be given prominent mention, rather than the number of its inhabitants. It is interesting to note that in the table of membership, submitted by the trustees in their annual report, Colorado has 327 members, a number exceeded by only seven other states, while only Pennsylvania, Illinois and Ohio have over 500 members each. Unquestionably, for her population, or for the number of her physicians, Colorado furnishes a larger number of members to The Association or any of its sections, and but one member of one committee was from Colorado. There seems to be no reason for this except excessive modesty on the part of the Colorado members, and indifference to the way in which the affairs of The Association are conducted. For instance, when the time came at which, according to the program, "Delegates from the various states meet in the places designated, for the purpose of electing one member from each state on the nominating committee," one solitary member from Colorado sat in the place designated, and listened to the pushing, and caucusing and vociferating of the delegations from other states around him. Then, when the allotted time had expired, not knowing who else from Colorado was in attendance, this solitary delegate sought the secretary and—at great strain to the modesty above mentioned—handed in his own name, that the state might not go wholly unrepresented. There is no reason either in lack of ability or in the attitude of delegates from other sections toward Colorado members why they should not take their fair share of the official life and honors of The Association. A wholly impromptu and unsupported attempt came within one vote of capturing for the state the Oration in Medicine, an opportunity which rightly used would be worth much to Colorado and more still to the profession and the people of other sections of the country. The mere medical politician may be the bane of our professional organization, but his opportunity lies wholly in the neglect of the better members of the profession to give sufficient time and attention to the essential details of organization.—*Denver Medical Times (August).*

Hematolysis Test of Molecular Concentration of Blood.—Changes in the molecular concentration of the blood and in its osmotic pressure can be tested by the hematolysis which occurs in solutions of sodium chlorid or nitrate in varying concentrations. It is a more sensitive test than determination of the freezing-point, and requires only a minute quantity of blood. Teissier derived important conclusions from it for his address on "Edema of the Lung" at the International Congress. He compared the hematolysis in blood drawn before and during experimental edema and thus estimated the decrease in the resistance of the corpuscles and the increase in the total molecular concentration of the blood under the influence of the pathogenetic intoxication. Defibrinated blood, 1 c.c., was added to 20 c.c. of one of the solutions in each of the ten test-tubes. The fluid was stained by the hemoglobin diffused by "*laquage*" in case of hematolysis. It first appeared in the 45 per cent. chlorid and 65 per cent. nitrate solution. As the edema progressed, hematolysis was apparent even in the 60 per cent. chlorid and the 75 per cent. nitrate solution.

SATURDAY, SEPTEMBER 1, 1900.

ANALGESIA FROM COCAINIZATION OF THE SPINAL CORD.

One of the outcomes of the International Medical Congress at Paris is the widespread popular interest in what the newspapers and to some extent the medical profession apparently accept as a new and epoch-making discovery in anesthesia. Professor Tuffier, of Paris, is announced as having made the discovery in March last that injections of a 2 per cent. solution of cocain into the spinal canal in the lumbar region is a safe and speedy way of producing what may be called a generalized local anesthesia, involving the lower limbs and to a greater or less extent the trunk, so that capital operations can be performed painlessly, but with full consciousness on the part of the patient. This removes from their places ether and chloroform as the indispensable anesthetics for the majority of surgical procedures, together with all their inconveniences and dangers. Not only surgery but obstetrics will be debtor to this discovery and it is announced as opening up a new epoch in medicine.

It is almost a pity to spoil a sensational announcement like this with bare facts that show that the new discovery is not by any means a new one, and that Professor Tuffier is not only not the discoverer but even not the first, merely the second, adapter and utilizer of the method. It is common enough that when some great fact is announced, some one will claim to have known it before, but in most cases with only such imperfect appreciation of its importance as not to detract from the last discoverer's merit. The knee-jerk had been a plaything of children from time immemorial until at last Westphal first pointed out its pathologic significance. Many Portuguese traders had probably traveled Central Africa, but they never gave their knowledge to the world, and Livingstone's and Stanley's renown was none the less well earned. The case is different, however, when a scientific man publishes in a scientific publication a fact that passes unnoticed until some late worker takes it up and popularizes it, so to speak; it is then our duty to recognize the service performed by the original investigator and not let the credit be misappropriated by one who, while he may have independently discovered the fact, has not real claim to priority.

The present instance is in point; neither Tuffier nor his predecessor, Bier, can rightly claim the origination of the method, which we owe to our fellow countryman, Dr. Leonard Corning, who, in his papers in the *New York Medical Journal* in 1885 and 1888, and his work on "Pain" published in 1894, left little to be developed of the method and technique of spinal analgesia. Not being a surgeon, he did not apply it directly to surgical procedures, but this does not impair his credit as the original discoverer. Its surgical application is a natural corollary to his pain-obtunding utilization of the method, and he has shown that it has a wider usefulness than merely a surgical one. Tuffier has simply extended Bier's application of Corning's discovery and neither of them can rightly claim to be its originator.

These facts have been published before. They were noted by Matas in his review of the surgery of the half century in the semi-centennial issue of THE JOURNAL published last year, as well as editorially in the *Medical Record* of August 5, 1899, and in THE JOURNAL of August 26, 1899. There has been no lack of opportunity for Bier or Tuffier to know these facts; they were not given out in obscure publications, but in leading journals and in a widely noticed work. It is perhaps only an instance of the truth recently noted by Virchow, of the superficial knowledge of many modern investigators in his and other countries as regards research to what others, especialy Americans, have done.

Whether this method, as adapted from Corning by Bier and Tuffier, is to work out the promised revolution in surgery and make a new epoch, time alone can decide; it is yet too new for positive predictions. It may be a question whether it will displace the time-honored anesthetics as fully as some may expect. But it does seem to promise at present a large addition to our surgical resources, and if further experience reveals no drawbacks to its use, no immediate or remote dangers of spinal cocainization, we can hardly overestimate its value. In this connection we refer to Dr. Murphy's communication in another column[1] showing in detail its latest developments in the hands of Professor Tuffier, and in which Dr. Murphy also gives his own experience.

THE REGISTRATION OF TUBERCULOSIS.

Concerning the dependence of tuberculosis on the tubercle bacillus, and the transmissibility of the disease, there is no longer any serious difference of opinion. The quibble as to whether we shall employ the qualification "infectious" or "contagious," as applied to tuberculosis, may now be relegated into obscurity. An infectious disease is one that is dependent on a specific cause that is capable of indefinite multiplication and through which it is susceptible of unlimited reproduction. Such a disease is necessarily transmissible or communicable by direct contact, through the intermediation of air, water, food, or other fomites, or a third person not necessarily suffering from the disease, but like the inanimate intermediaries acting only as a carrier of the infective material. In the category of such diseases belongs, among others, tuberculosis. Now, the especial danger of tuberculosis lies in the fact that the infective agents on which the morbid process depends are given off with the expectoration in cases in which the lungs are the seat of the disease; and, through only such carelessness, indifference or ignorance, as it can not be hoped the ordinary human being will ever be wholly freed from, the opportunities for diffusion will always be quite considerable, unless special restrictive measures are made operative.

---

[1] P. 572.

Being communicable, tuberculosis is to a certain extent preventable. All that would be necessary to bring this about would be the destruction of the causative agents or the cutting off of the channels through which they are conveyed. In both of these directions some progress has been made. The most practical means at our command looking to the fulfilment of these objects consists in isolation of the sick and disinfection of their discharges. In order to accomplish these purposes, however, it is obviously necessary to have cognizance of the cases, as well as the house, in which the disease exists. The methods to be pursued as an outcome of the knowledge thus acquired must have nothing of an inquisitorial or persecutory character, and there can be no thought of ruthlessly separating from their families unwilling tuberculous patients. Opportunity for isolation should, however, be afforded, but it must be made as attractive as possible for those who see the wisdom of it, not alone for the sake of those by whom they are surrounded, but also from the larger hope of improvement and recovery under the most favorable conditions for treatment. With regard to others, there should be some assurance that they shall not continue a menace to their neighbors or to the community in general. They should be taught, in however homely and simple a manner, the principles and the methods of prophylaxis, and they should be urged to practice them.

One step in the direction of these reforms would be the registration with boards of health of cases of tuberculosis that come to the knowledge of physicians. This has been undertaken in some cities. It would be well if it could be known where are the foci of disease, and, with this knowledge, enforce, humanely of course, the two main principles of preventive medicine, namely isolation and disinfection. For this purpose it would be necessary that cases be reported to some central authority, such as a board of health, and that proper steps be taken by such body in accordance with modern hygienic requirements.

THE FAUCIAL TONSILS AS POINTS OF ENTRANCE OF TUBERCULOSIS IN YOUNG CHILDREN.

The tonsils have been receiving a great deal of attention of late, because they are regarded as a possible and a probably rather frequent place of entrance of infections of various kinds. Diphtheria, scarlet fever, acute rheumatism, pyemia, and numerous other infectious diseases, all stand in more or less close relation to the tonsils. It has long been thought that tuberculosis—the most widespread of all infections—may gain entrance through the tonsils, especially in the young, in whom tuberculosis of the cervical glands is so common. Much has been written about this question, and its various phases have been quite fully discussed. Still, the subject can hardly be regarded as exhausted. Systematic studies on a large scale are best calculated to place the facts in regard to questions like this in their true light. Friedmann[1] reports the results of an extensive investigation covering the tonsils of 91 children examined after death, and of 54 living children whose tonsils were removed by tonsillectomy. It is necessary to exclude hematogenous and lymphogenous tuberculosis of the tonsils before a tonsillar tuberculosis may be interpreted as the result of a primary infection from without. This is easily done, because there is as yet no instance in which tuberculosis of the tonsils has been demonstrated to originate from the blood or lymph—Friedmann.

Infection from without may be primary and introduced by the food, and possibly under exceptional circumstances by way of inspired air; or it may be secondary and result from contact with bacillary sputum. Friedmann has several cases in which tuberculosis of the tonsils very likely developed from tuberculous food and milk. There is one case especially noteworthy: a marked tuberculosis of the tonsils without any other foci in the body. Friedmann regards it as quite certain that in childhood tonsillar tuberculosis is as frequently the primary result of infectious food as secondary from bacillary sputum. Tubercle bacilli lodged upon the surface or in the lacunæ of the tonsils are carried into their interior in the same way as solid pigment particles have been shown to be imported into the substance of the tonsils. From tuberculous tonsils an extensive invasion of the cervical or thoracic lymph-glands may develop. This Friedmann showed both in the living and the dead. In cases of cervical lymphatic tuberculosis, scars are often present in the tonsils, and these scars probably represent a healed tuberculosis. It is not likely that the tonsils constitute the entrance-point of infection without themselves becoming tuberculous, because Friedmann failed to find bacilli in non-tuberculous tissue. This corroborates Baumgarten's law that wherever bacilli enter, tuberculous changes result.

The general conclusions to be drawn from Friedmann's study are: In young children tuberculous invasion of the tonsils is of considerable importance, especially as to cervical glandular tuberculosis; and the infection is introduced in the food. In the end, we again are brought up before the fact that prevention is more important than efforts at cure.

The next International Medical Congress will be held at Madrid in 1903. Professor Calleja was elected president, and Dr. F. Caro, inspector-general of the Spanish navy, secretary-general.

HYSTERICAL PYREXIA.

Good definitions are wanting for both inflammation and fever. Each represents a morbid process of which the manifestations are, in general, well known. The one would appear to be the result of the local reaction of the tisues to certain irritants, while the other would seem to be the result of the entrance into the circulation of chemical substances capable of causing derangement of physiologic equilibrium. Perhaps the most distinctive feature of the febrile process is elevation of temperature. The two have, in fact, even been considered synonymous, but from the view-point of precision, it were better to distinguish the latter as pyrexia. Bearing this distinction in mind, the question may be fairly raised whether fever is ever unattended with elevation of temperature, and the evidence would suggest an affirmative answer; for there are on record isolated observations in which febrile diseases, such as typhoid and scarlet fevers, have pursued their course with slight, and even with no, pyrexia. It may, therefore, be inferred that the manifestations of fever are due to reactions excited by the products of abnormal metabolism, and that the presence or absence of any of those manifestations, such as elevation of temperature, will be governed by the presence or absence of certain definite chemical principles generated within the body, or even introduced from without. The individual susceptibility, in this connection, must obviously be quite variable. Thus, it is known that children, by reason of the greater instability of their nervous system, readily exhibit elevation of temperature on slight provocation; and the same is true, within limits, of emotional and mobile adults. It is, therefore, not surprising that the possibility of hysterical fever has been suggested, meaning more specially, hysterical pyrexia, and observations pointing in this direction have been placed on record.

After discussing some of the phases of this subject and citing a few cases from recent literature, Kobler[1] reports two illustrative instances under his own observation. The one occurred in a baker, 21 years old, who was seized repeatedly with hysterical convulsions and exhibited elevation of temperature between 102.6 and 107.6, without acceleration of pulse. Improvement in all of the symptoms followed a threat to place the patient in a bath of ice-water. The second case occurred in a girl, 11 years old, who presented attacks of screaming, with pain referred to the ileocecal region, motor aphasia, and elevation of temperature, ranging between 103.8 and 105.4, the symptoms setting in suddenly and subsiding with equal suddenness. After varied treatment, improvement followed only the threat of surgical intervention. The evidence thus seems to indicate that elevation of temperature may be of hysterical origin; but care must, of course, be taken to see that the registration of the thermometer be not induced by artificial means, and also that all other possible causes of pyrexia be excluded, or at least guarded against.

"OLD AGE WITHOUT DOCTORS."

Recently a lady died in Chicago who had attained the distinction of having lived over a hundred years. As is usual in such cases, the lay press proceeded to give the reasons why she had lived so long. Among these, the one given most prominence was the alleged fact that she had taken no medicine nor consulted a physician since she was 18 years old. This was twisted and enlarged on by other journals until it has appeared in a majority of the newspapers of the country, and has made a text for many an editorial against the doctors. An investigation, however, spoils the whole story, for it shows that the old lady had been under the care of the same physician for twenty-seven years, that for the past fifteen he had attended her for illness at least every three months, and all this time her life had been regulated by his advice. Verily, the evolutions of the inner consciousness of the average reporter evolve strange things, and his imagination beholdeth many things that are not!

THE EQUIPMENT OF THE MODERN PHYSICIAN.

The requirements of the scientific physician are yearly growing more exacting. Precision in observation and intelligence in treatment have become essentials in the modern practice of the art of medicine. The trend of current opinion in this connection is well indicated in an admirable and scholarly address delivered recently before the Ontario Medical Association by Dr. Lewellyn F. Barker,[1] late associate professor of pathology in the Johns Hopkins University, and now professor of anatomy in Rush Medical College, who states that were a medical student, suited by heredity and environment, to look forward to the higher things in medicine, to ask the question, "How can I best fit myself to make real advances in knowledge in medicine and therapy during the next twenty-five years?" he should say, "In addition to a thorough medical course, arm yourself with sufficient mathematics and gain a thorough theoretical and practical training in the methods of physics and chemistry, and especially in the principles and methods of what is called physical chemistry. After this, turn your attention to the solution of medical problems."

THE INCIDENCE OF PHTHISIS.

On another page of this issue is given an abstract from the *British Medical Journal* of a paper by Sir H. R. Beevor that is suggestive and noteworthy. Assuming that the death-rate is the most reliable index of the incidence of phthisis, he takes the little rural districts as affording the most stable conditions of population and environment and shows a uniformity in the statistics of phthisis that seem to him the "most cogent evidence of the insignificance of case-to-case infection; the rates are far too regular for so variable a factor to be the determining factor." He quotes Andvord, who from a careful inquiry into the tuberculous deaths in five Swedish towns for sixteen years came to the same conclusion. It seems from the studies of both of these observers that other contributing causes, and more especially predispositions, are the ruling factors in the phthisis mortality. Contagion, of course, must be admitted as possible, but it cuts no figure in the general statistics, according to these authorities. The figures and diagrams of Dr. Beevor are most encouraging in that they show an almost uniform decrease in this mortality for each of the three decades between 1860 and 1890, due, it seems, to better modes of living and diet and corresponding increase of physical stamina. Infection alone is significant enough, he says, as a pathologic factor, but it is other contributory causes that really determine when the disease shall manifest itself.

SPONTANEOUS GANGRENE.

The disease known as spontaneous gangrene develops in the young and in strong adults. Usually there is no history of any special, preceding illness. Preceded by the rheumatoid pains and circulatory disturbances in first one and then the other lower extremity, and by a tendency to exhaustion on slight exertion, evidences of gangrene appear in some peripheral part of the extremity most affected. Occasionally the disease may affect the upper limbs. All therapeutic measures are fruitless, and amputation must be resorted to either on account of the extent of the gangrene or on account of the pain. The amputation must be made high above the limit of the gangrene, because the arteries are more or less completely occluded far above the diseased territory. Microscopically the vessels, especially the arteries, are narrowed or occluded by connective-tissue growth on part of the intima—a productive, obliterative endarteritis. The media often appears thickened. Evidences of calcification and degeneration are usually but little marked. The explanations advanced in regard to the endarteritis of spontaneous gangrene have not been satisfactory, hence their number has rapidly multiplied. The cases have occurred mostly in certain parts of Russia and Austria. Sternberg[1] reviews the whole subject of endarterial connective-tissue growth and reaches the conclusion that for the present the endarteritis of spontaneous gangrene is best explained according to Thoma's general law that whenever a vessel, owing to dilatation or other causes, becomes too large for the territory it supplies, a compensatory narrowing produced by intimal thickening results. Owing to congenital weakness, or to the great strain to which the arteries of the lower extremities are exposed, dilatation followed by endarteritis results. So far this explanation is plausible. But it does not make it clear why the endarteritis, a compensatory and regulative process, proceeds to complete occlusion of the vessels and thus causes gangrene, a condition far worse than the one it is assumed to relieve in the earlier stages of its development. The pain characteristic of spontaneous gangrene is ascribed by some to irritation of cutaneous sense-organs by the circulatory disturbances, by others its origin is referred to the Pacinian corpuscles in the adventitia of blood-vessels.

SEPTICOPYEMIA, SIMULATING BUBONIC PEST, AND CAUSED BY AN ANAEROBIC BACILLUS.

There are but few anaërobic pathogenic organisms as far as we know, but it is very likely that instances of such infections *escape recognition* often because not examined systematically with the proper methods. One of the most interesting and important anaërobic bacilli, gifted with high pathogenic powers, is the gas bacillus of Welch. Since the attention was directed to the bacillus of Welch, the number of morbid conditions found to be caused by it have multiplied rapidly. This shows what may be the case in other forms of anaërobic infections. Courmont and Cade[1] recently describe with great fulness of detail an exceedingly interesting example of an acute, fatal infection with an anaërobic bacillus that seems to be a new pathogenic organism. Clinically there was much that reminded one of the bubonic pest: violent general symptoms, ill-defined signs of pulmonary involvement with blood-tinged expectoration, subclavicular phlegmonous swellings. Pest was easily excluded, however, by finding in the pus an anaërobic bacillus, non-pathogenic for mice. Post-mortem there were found multiple abscesses of the lungs, a subclavicular suppuration, and the changes peculiar to septicemia of infection in the viscera. The pus contained great numbers of small bacilli, often arranged in chains, but also in various other groupings. Cultures from the lungs and the abscess, made anaërobically, gave pure growths of a bacillus, mostly in chains, which destained by Gram's method but stained readily with the usual other stains, often showing an unstained spot in the center. The bacillus is a strict anaërobe, and the anaërobic cultures from the other organs remained sterile. It grows best in peptonized bouillon, forming flocculi at the bottom, the supernatant fluid remaining clear. On solid media but slight growth is produced, non-gasogenic. It is pathogenic and pyogenic for rabbits, guinea-pigs, and dogs. After intravenous injections of rabbits large abscesses of the liver frequently result. In proposing for this bacillus the name "strepto-bacillus pyogenes floccosus" the authors violate one of the canons of botanic nomenclature, in so far as a trinominal name is suggested. We have here a good illustration of the value of systematic and complete bacteriologic examination in cases that simulate such dreaded diseases as bubonic plague.

THE QUESTION OF CRUELTY IN THERAPEUTIC OBSERVATIONS.

It is thought by some persons that members of the medical profession become hardened to suffering and death by reason of their more or less constant association with both of these conditions; but investigation will disclose that there is no body of men more thoughtful and considerate for the comfort and welfare of those that come under their care. Occasionally in the pursuit of his duties, the medical man may be compelled to resort to measures that to the layman may seem unnecessarily harsh and severe. The cold bath, for instance, has been considered such a measure. Again, many patients do not consider milk a food, and complain bitterly of being starved if given no other nourishment. *It is, therefore, incumbent on the physician to be* especially careful in experimental observations, as well as guarded in his manner of description, in order that both his motives and his methods be not exposed to hostile and unjust criticism. Several years ago a great hue and cry was aroused because of the administration of thyroid extract to a number of cases of dementia in the course of a perfectly legitimate and well-intended therapeutic experiment. As a further illustration of the distorted and exaggerated interpretation that is every now and then placed on medical reports, an account of a recent experience is an interesting example. There was published in the *Archiv für Klinische Medicin,*[1] by an assistant of the medical clinic at Jena, a description of the methods pursued in a case of diabetes insipidus, in which the amount of water permitted for drinking-purposes was greatly restricted, so that the patient, as a result, suffered greatly from thirst, and secretly obtained water and other fluids. The report goes on to say that he was accordingly locked in a room, and, to relieve his thirst, drank dirty water, as well as his own urine. With the appearance of untoward symptoms the treatment was discontinued. As might be expected, this report gave rise to considerable acrid criticism, not alone of this particular case, but of the medical profession generally. In defense of the course pursued, it is pointed out by the chief of the clinic where the observations were made that the treatment was instituted purely for curative purposes, that the patient had been informed of the inconveniences to which he might be subjected, that he nevertheless consented to be treated in this way, that he was at liberty to leave the hospital whenever he chose, but that he remained for two months and afterward returned of his own accord, and that, although the events described occurred three years previously, the patient had been up to the time of his death, two years later, always grateful to the physicians of the clinic for the consideration shown him.

Medical News.

PROF. K. GEGENBAUER, professor of anatomy at Heidelberg, has resigned his chair on account of ill-health.

SIR MICHAEL FOSTER, professor of chemistry at the University of Cambridge, England, is in San Francisco and will give a series of lectures on the science of physiology, at Cooper Medical College.

PROF. A. VON ROTHMUND retired from the chair of ophthalmology at Munich on his seventieth birthday, August 1, after an incumbency of forty years, at which time his friends, pupils, and representatives of the municipality and local societies, etc., assembled to do honor to his farewell address.

THE CITY OF MOSCOW founded a prize in 1897 in honor of the International Medical Congress, to be awarded triennially to the author "whose works have contributed most to the progress of medical science." The Thirteenth Congress bestowed this prize of $1000 on the Spanish scientist, Professor Ramon y Cajal, of Madrid.

LUNG DISEASES are increasing in the Royal navy, says Captain Rason. Since 1883 respiratory diseases in that service have increased 60 per cent. despite the abolition of masts and sails and the lessened exposure to cold and wet. Captain Rason suggests as possible causes for this increase, that the men live in hot, unlined steel ships and crowded together.

TUBERCULOSIS has been decided by the Secretary of the Treasury and the Commissioner of Immigration, to be a contagious disease, and aliens ill with the disease will not be allowed to land in the United States. The first sufferer under this decision was a Japanese clergyman, who was not allowed to land at San Francisco. He appealed and the decision cited above is the result.

HOSPITALS are to be established for United States soldiers at Nagasaki, Japan, with a capacity of 500 beds, and at some point in China with double that capacity. The material for fitting up these hospitals is being collected and forwarded as rapidly as possible. Majors E. T. Comegys, and P. F. Harvey of the army medical department started on August 20 and will assume charge as medical-supply officer, and surgeon-in-charge of the base hospital at that point.

ROMA SALUBRIS, should be the name of the Italian capital, according to the statement of Dr. Irving C. Rosse, of Washington, D. C. He discredits the mosquito-borne theory of malaria and gives the city a very good name for salubrity. He says that malaria is now seldom observed excepting among the lower classes, notwithstanding the fact that the mosquito is not a respecter of persons. He further says that Rome—with the exception of London—is the best watered, the best drained, and the healthiest capital in Europe, and a European or native of New England runs greater risk of contracting malarial fever in Washington.

RUSSIA'S STUPENDOUS ANTI-ALCOHOL CAMPAIGN.—It is now five years since the Russian government assumed exclusive control of the manufacture and sale of alcoholic liquors. In nearly all the provinces the saloon has been supplanted by the government shops, in which a guaranteed pure article is sold in a limited quantity to each customer. None is sold to those already intoxicated. These shops are located quite a distance apart and no one is allowed to drink liquor on the premises where sold. The system is supplemented by officially appointed local committees in each large town, which are supplied with funds to establish attractive temperance restaurants, reading-rooms, and people's palaces. They are expected to maintain a general crusade against the use of alcohol. A portion of the enormous profits of the liquor monopoly is devoted to this purpose.

CALIFORNIA.

DR. HENRY B. BESSAC, Forbestown, has returned from Cape Nome, decreased in weight, but improved in health.

SAN FRANCISCO PLAGUE REPORTS.

CASE No. 14.—William Murphy, aged 34 years, male, Caucasian. Occupation, clerk. Born in California. Residence, 427 Dupont street, between Bush and Pine, this within a few blocks of the Chinese quarter. The patient rode out to the hospital in a car and was admitted to Ward C. The following history of the case was taken from the records of the City and County Hospital. He has smoked opium and used morphin hypodermically for the last nine years. Chills and fever seven or eight years ago and was also treated in this hospital for pain in the side and discharged cured in three or four days. No venereal history, constipated for the last nine years. On Tuesday afternoon August 7, he noticed a pain and slight swelling in the right groin. That evening he began to feel sick and sore all over, had some headache and vomited a small amount of a bitter greenish substance. Heart slightly enlarged to the right. Lungs dull in axilla and diminished resonance over both apices, anterior and pos S and sonorous râles over both lungs. Abdome sation normal. Urine, specific gravity, per cent., no sugar. Microscopic exam crystals and some pus cells. The tempe the range of temperature to have been from normal to 100. Pulse 100. A painful bubo was present in the right femoral region. The patient died August 11 at 8:20 a. m. Duration of illness five days. Autopsy performed August 11 by Prof. Taylor of the medical department of the University of California. "Body of a well nourished man apparently 30 years old. The face, neck and extremities are livid. The entire surfaces of the arms are covered with small scars. Rigor mortis moderate in degree. On section the tissues are bloody; panniculus adiposus exceptionally thick. Peritoneum covering intestines is injected; intestines present several dark patches suggestive of hemorrhages. No serous effusions. Thoracic muscles deep red in color. Diaphragm on right side extends to fifth rib, on left side to fourth. Both pleural cavities, numerous adhesions. No exudate. Pericardium contains an excess of clear fluid. Heart and great vessels filled with heavy postmortem clots. Weight of heart, 410 grams. Walls one-half thicker than normal. Muscle, deep red. Aortic valve soft, elastic and competent. Aorta, few patches of atheroma. Aortic orifice, enlarged, admitting three fingers. Mitral valve, slightly sclerotic. Right lung, crepitant throughout; exudes frothy serum on section and pressure. The bronchi contain pus. Up to the third ramification of the bronchial tubes they contain no hemorrhages and no free blood. Bronchial glands not enlarged. Left lung, deeply congested in lower lobe and presents a gelatinous feel and appearance suggestive of disseminated tuberculosis; otherwise like the right. Mesentery, has a mottled appearance; glands not enlarged. Common bile duct pervious. Stomach, a tremendous injection and submucous hemorrhage; not dilated, mucous membrane smooth, no ulcers. Spleen, weight 615 grams, deeply congested, very friable. Duodenum is slightly injected, no free blood in stomach. Extensive hemorrhages into the tissues about the pancreas and behind the lesser peritoneum. Extensive hemorrhages into the substance of the pancreas. No fatty necrosis. Liver is bound down by posterior adhesions; weight 2330 grams. Extends below the umbilicus. Increased in anteroposterior diameter. On section, pale, somewhat resistant to knife, and of fibrous appearance. Gall-bladder is not enlarged; contains one ounce of dark-colored bile and two gall-stones. No obstruction in common duct. Intestines show mucous membrane congested; numerous submucous hemorrhages; no ulcers. In right groin are two enlarged lymph-glands, hemorrhagic but not purulent. An enlargement of the glands in the right femoral region." Dr. Taylor left intact the bubo in the right femoral region for the bacteriologic examination. The next day, Dr. Kellogg, in the company of Drs. Kinyoun, Ryfkogel, and Pillsbury, removed the glands from the bubo and found them necrotic, full of hemorrhages, and larger than in any previous case. Microscopic examination of the glandular tissue and spleen showed the plague bacilli, typical in form, and in much larger numbers than usual. Guinea-pigs were inoculated and died of typical plague infection. Other guinea-pigs have been inoculated with pure cultures obtained from the glands and spleen. Case No. 15.—Ham Tam, Chinese, male, residence 900 Dupont street, died August 15. He had been treated by a white physician who has a large practice among the Chinese and who reported that the death was due to phlegmonous erysipelas and septic pneumonia. Dr. Kellogg saw the case August 16, and found an enlargement of the submaxillary glands on the left side, which were removed and found to contain the plague bacillus in large numbers. Guinea-pigs were inoculated with emulsion made from the gland and died with typical lesions of plague. Pure cultures have also been obtained from the gland. An autopsy of the Chinaman showed nothing aside from what could be expected in cases of plague. The heart was soft and flabby and valves normal. Decomposition was well advanced and all the cavities were distended with gas. The lungs were much congested but no consolidation. Vessels of the mesentery injected. Spleen enlarged, very dark and soft. No enlargement of the lymph nodes.

---

[1] THE JOURNAL, July 28, p. 247.

CONNECTICUT.

Dr. Joel Butler, Meriden, has been appointed junior house-surgeon of the New Haven Hospital.

The July examination, held by the examining board of the State Medical Society, was taken by twenty-five, sixteen of whom, including one woman, passed. The examining committee consisted of Dr. H. S. Fuller, Hartford; Dr. Max Maithouse, New Haven; Dr. J. F. Calef, Middletown; Dr. J. W. Wright, Bridgeport, and Dr. W. L. Barber, Waterbury.

The mortality of Connecticut for July, as shown by the report of Dr. C. A. Lindsley, Secretary of the State Board of Health and superintendent of vital statistics, was greater by 214 than the corresponding month of 1899. During the month 1583 deaths were reported. This mortality was exceeded in March and April, in which respectively 1691 and 1678 deaths occurred. The highest mortality was, of course, from diarrheal diseases and among infants. The death-rate per 1000 for the state was 20.8; for the large towns, 21.7, and for the small towns, 18.7.

GEORGIA.

Drs. William S. Goldsmith and Walter B. Emery, Atlanta, have gone to New York for post-graduate work.

More than 3000 insane are now inmates of the state asylum at Milledgeville, which is greatly overcrowded, and more than 200 are now being held in county jails waiting for vacancies in the state institution. New buildings and increased space are urgently needed.

ILLINOIS.

Dr. Ralph Graham has located in Seaton for the practice of medicine.

Chicago.

A lawn party was given August 22, with a musical and literary program, for the benefit of the Norwegian (Tabitha) Hospital.

An emergency hospital is to be established in the stockyards district. At present those injured in the stockyards must be transported several miles to the County Hospital for treatment.

Dr. Charles H. Beard has returned from Paris, where he served for two months as a member of the international jury of awards in the department of medicine and surgery at the exposition. He accords high praise to the exposition, and says that every courtesy was shown to the American members of the jury.

The committee on lodging-houses of the State Board of Health, and its Chicago inspector, will ask the board to draft a law for the government of lodging-houses more in accordance with the law now in operation in New York. More rigid sanitary regulations will be included in this law, which, if enacted and enforced, should take away Chicago's reproach in this regard.

La Rabida Sanatorium, in Jackson Park, has been a godsend to the sick babies of the South and Southwest sides of the city during the heated season. Dr. Emma M. Mora is the physician-in-charge and the medical board is composed of Dr. M. P. Hatfield, president; Dr. W. C. Williams, vice-president; Dr. Henry F. Lewis, secretary, and Drs. Rosa Engelmann and J. C. Cook, consultants.

HEALTH DEPARTMENT.

From time to time during the last ten years, and more frequently since 1895, the department has claimed that Chicago had a lower death-rate than any other large city in the world—including among "large cities" all those having populations of more than 500,000. With the uncertainty as to our population it was not possible to demonstrate the correctness of this claim and elsewhere it was set down as a wild western bluff. One high statistical authority commenting on the figures for 1893, asserted that a death-rate of less than 18 per 1000 for a city of a million was incredible and added that, "If Chicago's figures are correct, municipal hygiene is a municipal farce; if they are correct there can be no use for a health department." More recently, one of Chicago's self-constituted censors who finds no good in his own city, publicly stated, with much apparent satisfaction, that the Berlin authorities —from which city he had just returned—paid no attention to Chicago's statistics—"they threw them in the waste basket."

Announcement last week of the Federal census figures of population not only sustains the claim of lowest death-rate for Chicago but also shows that the department estimate of population was nearer that of the Federal census than were those of any other of the large cities yet announced. Greater New York had an estimated population of 3,654,594; the census figures were 3,437,202, a difference of 6.32 per cent.; St. Louis an estimated population of 623,000, reduced census figures to 575,238 a reduction of 8.30 per cent.; Philadelphia claimed 1,266,832, but the census-takers found only 1,203,697, a reduction of 5.24 per cent; while the estimate of the Chicago department of health—1,750,000—was only 51,425, or 3.03 per cent. above the census findings. The claims of Chicago are confirmed by the statistics of deaths tabulated in the current number of the "Sanitary." From this table it appears that Chicago leads the cities of the world as regards death-rate for the first quarter of the year, 16.56 per mille. Next in order comes Brussels, 16.8; St. Louis, 19.2; Hamburg, 19.4 Berlin, 20; Amsterdam, 20.8: Vienna, 22.1; London, 23.1; Naples, 23.2; Greater New York, 23.27; Philadelphia, 23.65; Paris, 23.8; Birmingham, 25.9; Manchester, 26.5; Glasgow, 27.4; St. Petersburg, 29.5; Liverpool, 31.4; Budapest, 32.6; Cairo, 32.8, and Moscow, 36.9. In the half decade 1890-1894, there were 126,804 deaths in Chicago, a yearly average of 23,361; in the half decade, 1895-1899, 117,331 deaths occurred, a yearly average of 23,516. This marked a decrease of 7.27 per cent. in mortality as compared with the first period, while the population in the same period had increased according to census figures 37.33 per cent. This is a most interesting and instructive demonstration of the improving public health of Chicago. From this time on the department will base its figures on the population as found by the census authorities, 1,698,575. The mortality for the week ended August 25, was at the rate of 14.42 per thousand, which compares favorably with 15.40, the figures of the corresponding week of 1899. The total deaths were 466; 262 males and 204 females; 140 under 1 year, 65 between 1 and 5 years and 65 over 60 years of age. The principal causes of death were: acute intestinal diseases, 109; consumption, 42; heart diseases, 39; violence, 33; nervous diseases, 26; cancer, 25; Bright's disease, 18; pneumonia, 17; convulsions, 11; typhoid fever, 11; diphtheria, 10; sunstroke, 7; and suicide, 3.

INDIANA.

Dr. A. J. Boswell has moved from Fort Wayne to Elkhart.

Dr. A. B. Darby, Waterloo, has been nominated for state senator on the republican ticket.

Dr. Fred C. Sarver, Scottsburg, will soon leave for China as acting assistant-surgeon in the army.

In a fight over the way in which Dr. N. G. Masters of Stilesville handled an alleged mind-reader, he seriously wounded the manager of the show.

Dr. Charles R. Shouse, house physician of the Wabash Hospital, Peru, has been transferred to the Wabash Hospital at Ashley, succeeding Dr. P. S. Kaadt.

Muncie is promised a $100,000 hospital by the woman's lodges and various societies of the city. They agree not only to build and equip the hospital, but to assume its management, and all this without "begging one cent."

The State Medical Board report, just issued, shows that the medical profession of the state has approved the medical laws recently enacted and that their enforcement has rid the state of many undesirable practitioners. The board considers that all the medical colleges of the state are operating within the requirements of the law. It is suggested that the laws of the state be so amended as to require graduates from colleges in other states to pass an examination by the state board before being granted license to practice. It is also suggested that the law be so amended as to require each county clerk to file in his office all cetificates of qualification presented by applicants for license to practice.

KANSAS.

A partnership has been formed by Drs. W. Scott Harvey and James R. Crawford, Salina.

Morton County, when asked by the State Board of Health to send in a list of its physicians and surgeons, reported that it had none. On investigation the state board is said to have learned that there had not been a case of serious illness in the county for two years. This locality is earnestly commended to the attention of the pathogenic microbe.

KENTUCKY.

Speers Hospital, Dayton, will probably not be closed. On August 17 the medical staff met at Newport, discussed the troubles of the institution, decided on the abatement of certain abuses and determined to use its utmost efforts to continue the work of the hospital.

LOUISIANA.

Dr. Otto Joachim, of New Orleans, is spending his vacation in Quebec, Canada.

New Orleans is boasting of her health record. Her death-rate for the week ended August 11 was only 13.11 per 1000 per annum for whites; and for the following week, 13.87 per 1000 per annum. The death-rate for the colored population is not given. Out of 56 deaths for the week, 4 were from accident, 1 of which was from sunstroke.

MARYLAND.

Dr. John D. Brooks, Brookland, left for San Francisco August 17 to receive orders as acting assistant-surgeon in the army. He expects to go to the Philippines.

Baltimore.

Dr. William T. Howard is at Narragansett Pier.

Professor John C. Hemmeter, of this city, read a paper before the International Medical Congress in Paris August 3. During his stay in the Parisian capital Dr. Hemmeter is the guest of Professor Mathieu.

In a card in the papers, Dr. Brush, of Sheppard and Enoch Pratt Asylum, states that there are no cells, "either padded or otherwise," at his institution. Padded rooms are quite common in many English hospitals for the insane.

Dr. Calvin De Ford Snyder, who for eighteen months past has been resident gynecologist at the Maryland University Hospital, and Dr. Howard D. Lewis, who has been connected with the hospital dispensary for some time, have been appointed assistant-surgeons in the U. S. Army, with the rank of first lieutenants, and have left Baltimore for San Francisco.

The Board of Awards has let the contract for supplying horses to the health department for the next year for $500. This includes the use and keep of two horses and wagons. The horses are needed for the pauper dead service and for carrying sick persons to hospitals. Should extra horses be needed they are to be furnished at the rate of $250 each per annum.

By the will of Mrs. Margaret J. Bennett, of this city, widow of a wealthy auctioneer, the following bequests are left to charity: Hospital for the Women of Maryland, $25,000; Nursery and Child's Hospital, $2,000; Asylum and Training School for Feeble-Minded of Maryland at Owing's Mills, Baltimore County, $1,000; Home for Incurables, $1,000; for establishing a home for homeless, needy and deserving female persons, $150,000. Altogether $316,000 of her million were left to charity.

MASSACHUSETTS.

Dysentery is reported to be epidemic in Millbury, and the local health authorities are looking into its causation.

State medical inspectors are recommended by Dr. Henry P. Walcott, chairman of the State Board of Health, whose duties shall be to make frequent inspections of nuisances with immediate reports to the local and state boards. He proposes that the present district examiners be appointed, as they are "the most reputable men the state employs" and who "know something about law and could go into the courts if necessary."

Anti-vaccinationists of Rockland have passed resolutions asking the local board of health to refrain from further enforcement of the state law that requires all children to be vaccinated before entering the public schools. Dr. Gilman Osgood, of the board, in a communication to the local press, defends vaccination in strong terms and stated that parents who failed to have their children vaccinated were guilty of wilfully neglecting their welfare.

MICHIGAN.

Dr. Willett J. Herrington, of Bad Axe, has returned recently from his European trip.

Drs. W. E. Jewett, Sr., and W. E. Jewett, Jr., have been appointed surgeons of the S. & M. S. Ry. at Adrian, vice Dr. C. Kirkpatrick, resigned.

Dr. Harry S. Kiskadden, Detroit, has been appointed by the governor a member of the State Board of Health to succeed Dr. B. H. Lawson, resigned.

MINNESOTA.

Dr. John Snell Holbrook, Mankato, and Miss Mary Emaline Whiting, Northfield, were married August 16.

Dr. G. R. Clayton, Winona, has been appointed acting assistant-surgeon in the army and is in San Francisco awaiting orders.

The incorporation is announced of the Swedish Hospital and Nurses' Institute, at Minneapolis, with a capital stock of $30,000. The incorporators are Dr. C. A. Smith, A. B. Darelius, E. G. Dahl, and N. O. Warner.

The citizens of Minneapolis have been asked to contribute $30,000 for the building of a quarantine hospital. The city treasurer is to act as treasurer of the fund. This appeal has been made because the city treasury is empty and no money will be available from municipal sources until next year.

MISSOURI.

Dr. A. M. Conway, of Fayette, has removed to Glasgow.

Three murders were committed on August 20 by Dr. Sturley P. Harrington, Farley, Platte County, while crazed from drink. He first drove his wife from the house, killed his uncle, mother-in-law and the sheriff of the county, and was in turn shot dead by the sheriff's son.

NEW JERSEY.

Dr. Edwin Field, Red Bank, sued the Board of Chosen Freeholders of Monmouth County for $90, for performing three autopsies. The board, which had an arbitrary rule, refused to pay him more than $15 per autopsy. The court, however, held that he was entitled to the amount claimed.

NEW YORK.

Dr. Smith Ely Jelliffe assumes charge of the *Medical News* September 1.

NORTH DAKOTA.

Dr. George F. Erskine, Hamilton, has been appointed vice-president of the State Board of Health to succeed Dr. Musgrove, deceased.

Diphtheria at Valley City and smallpox among the Indians on the Turtle Mountain reservation are engaging the time and attention of the state health officer, Dr. Quarry, Grand Forks.

OHIO.

Dr. A. O. Ervin, South Salon, has located at Washington Court House.

Dr. Scuyler O. Giffin, Columbus, has been elected secretary of the Franklin Park commissioners.

Dr. August Ravogli, for sixteen years Italian consul in Cincinnati, has been obliged by the demands of his practice to resign his diplomatic position.

Dr. Robert E. Ruedy, of the house staff of the State Hospital, Columbus, has resigned and will open an office in Cleveland. He will be succeeded by Dr. George T. Harding, of Marion.

Ohio Medical College, Cincinnati, will open a physiological laboratory with the opening of the autumn session, which will be fully equipped and will be under the charge of Dr. William Muhlberg, an alumnus of the institution.

The Board of Health, Portsmouth, has arrested three prominent physicians. They are charged with failing to report cases of contagious disease to the Board of Health within twelve hours, as required by the state law.

The care of the city poor of Columbus was awarded August 15, supposedly to the lowest bidder. The bids varied from $84 to $294 per ward for the year. The aggregate amount of all bids for the entire city for the year was $3,379. Whether the sick poor or the doctor would be likely to derive any benefit from the service thus rendered is a matter of grave doubt.

The first examination under the Love medical law will be held in Columbus by the State Board of Medical Examination and Registration, September 11, 12 and 13. Applications must be filed with the secretary of the board at least ten days before the date of examination. The requirements are that the applicant must have had a four years' course in some recognized college of medicine and in addition, pass the required examination.

PENNSYLVANIA.

Dr. Erwin F. Benner has decided to locate in Richlandtown.

Dr. H. C. Brunner, Treverton, was seriously injured by being thrown from his carriage on a mountain road, August 13.

Dr. Frank L. Moyer, Williamsport, has removed to Loganton, where he will be associated with Dr. Goodman.

Two resident physicians, Drs. Samuel Blose, McKeesport, and Howard P. Repman, Wampum, have entered on their duties at the McKeesport hospital.

Dr. Lucas C. Kennedy, a graduate of the University of Pennsylvania, for two years interne at the Moses Taylor Hospital, has returned from a study trip in Europe, and has opened an office in Scranton.

Several days ago a man living near Ephrata went in bathing in an adjoining creek and at night suffered severely from earache. Toward morning the pain grew worse. Medical attendance was called and two leeches were removed from the ear, giving relief of the symptoms.

The Association of Hospital Superintendents met in the Hotel Schenley at Pittsburg on August 21, there being 50 members present from New York, Philadelphia, Cleveland, Chicago, Buffalo, Detroit and other places. A paper on "Three Years' Growth and Development of Hospitals" was read by Dr. D. T. Sutton of Detroit.

Some physicians of Washington and Green counties are said to have been swindled by the old "signature" confidence game. A smooth stranger requested their signatures to a petition for the repeal of a law obnoxious to the profession. They signed the petition. Soon thereafter checks or notes were presented at banks, signed by these confiding physicians, who have been mulcted in sums varying from $20 to $50 by this means.

During the past week an unusual number of mad dogs have been reported in different parts of Pennsylvania and the disease seems to be increasing. On August 24 a white fox terrier afflicted with rabies entered Norristown, and before it was killed bit over a dozen children and probably as many dogs. The dog was subsequently killed. On the same date a shepherd dog in the Monongahela Valley near Pittsburg was found to have bitten 18 people.

Dr. McCuaig, of the new insane asylum at Wilkesbarre, went to Danville on August 24 and removed 83 insane patients to the asylum at Wilkesbarre. This list about completes the number who had been placed there some time ago owing to the overcrowding. Altogether 180 patients have been removed from Danville, 26 from Wernersville, and 21 from the Hillside Asylum near Scranton.

Philadelphia.

Dr. Charles P. Noble is expected to return from his European trip September 3.

Dr. Ellwood R. Kirby has been appointed a member of the Board of Charities and Corrections.

W. B. Saunders & Company, medical book publishers, are striking out for new fields, having established a branch in London.

Dr. Elizabeth Reifsnyder, a graduate of the Woman's Medical College of this city, and who for several years past has been practicing medicine in Shanghai, China, is now visiting in this city. Dr. Reifsnyder is assisted in the hospital work by Dr. Emily Gardner, also a graduate of the Woman's Medical College.

Dr. Samuel J. J. Kelly has sailed for Europe, where he will do post-graduate work.

Dr. Simon Flexner is spending the summer at Ty'n-y-Coed, Campobello Island, New Brunswick.

By a trolley accident, Dr. Thomas A. Downs had his foot badly crushed August 14, so that it was necessary to remove him to the Presbyterian Hospital.

Through the bequest of Michael Corr the sum of $5000 has been given to each of the following named hospitals for the endowment of a free bed: the St. Joseph's Hospital, St. Agnes Hospital and St. Mary's Hospital.

The twenty-sixth annual reeport of the Jewish Maternity Association states that during the year 129 persons have been cared for in the hospital and 33 operations performed. At present there are 650 contributors. During the past year the total amount of money contributed was $4853.23.

By the will of Sallie M. Waln, the sum of $3000 has been given the St. Christopher's Hospital for Children for the endowment of a free bed; to the Pennsylvania Training School for Feeble-Minded Children at Elwyn, $5000; and to the Children's Hospital $3000.

The number of deaths which occurred in this city for the week ending August 25 was 372, as compared with 550 deaths for the week preceding and 406 for the corresponding period of last year. The principal causes of death were: Nephritis, 33; cholera infantum, 26; tuberculosis, 37; apoplexy, 9; diabetes, 2; heart disease, 20; inanition, 23; pneumonia, 15; appendicitis, 2; surgical shock, 3; cancer, 7; sunstroke, 5; suicide, 4; tetanus, 2.

Owing to the spread of cases of conjunctivitis an investigation has been ordered by the board of health. The latest theory in regard to the prevalence of the disease is that it is due to the public bath-houses. It is stated that at the St. Christopher's Hospital for Children during the past three or four weeks upward of 200 cases have beeen treated, while the Pennsylvania Hospital has treated nearly as many. At the Jefferson Hospital and Polyclinic an increase has been noted. Some of the patients admitted that they had been patrons of the bath-houses. Dr. J. H. Taylor is quoted as saying that the rules at the bath-houses were very strict, and further after an investigation he could find no cause for infection in these places. Chief Good also did not believe the prevalence of the disease could be traced to this cause since each pool was scrubbed out twice a week, while running water is allowed to flow through these places constantly. Officers of the board of health still attribute the disease to colds resulting from trolley rides.

RHODE ISLAND.

Dr. John G. O'Meara, Providence, who has been resident physician at St. Mary's Hospital, Philadelphia, for a year, has sailed for Europe, where he expects to do post-graduate work, particularly in the line of physical diagnosis.

SOUTH DAKOTA.

Dr. Willis E. White, late of Tiffin, O., has located in Centerville.

TENNESSEE.

Dr. Eaton K. McNeil, Jackson, has sailed for Europe to do post-graduate work in Paris, Vienna and Berlin.

Dr. Alfred S. Horsley, Knoxville, will soon leave for Ecuador, South America, where he will be surgeon for a firm of railroad contractors.

St. Thomas Hospital, Nashville, is to receive an addition costing $100,000. The cornerstone of this annex was laid on the afternoon of August 15 with appropriate ceremonies.

Dr. G. M. Magruder, U. S. M. H. service, who has been for the past nine months in London, where he was detailed as special government officer to watch for the appearance of the bubonic plague in England, has returned to Memphis and resumed charge of the United States Marine Hospital in that city.

Dr. J. L. Andrews, chief sanitary officer of the city of Memphis, has resigned his position, with a view to pushing his interests as a candidate for the office of physician-in-charge of the County Poor and Insane Asylum.

Dr. J. A. Griffin, of Friendship, was recently nominated for representative in the General Assembly from Crockett County.

TEXAS.

The Medical Board of the Thirty-third Judicial District met at Mason, August 14, for permanent organization and examination of applicants.

VIRGINIA.

The Norfolk sanitary inspectors' report shows that there were in that city 593 cases of contagious disease with 80 deaths. The pest-house was kept open and 268 persons were there cared for at an expense of $3026.30. During the year 218 houses, containing 693 persons were quarantined.

WISCONSIN.

Dr. Egbert E. Loomis, Janesville, has returned from an extended tour in the East.

Dr. Arick Sutherland has located at Brodhead and will practice in partnership with his son.

Passavant Hospital, Milwaukee, now has six wards with 90 beds, beside 26 rooms for private patients. During the last year 663 in-patients, including 85 children, were cared for.

CANADA.

British Columbia.

LODGE PRACTICE.

The correspondence in the lay press of Victoria in regard to lodge practice in that western city is interesting. When the lodges of Victoria found that they could not engage any of the physicians of that city to do this work for them, they advertised for practitioners to come to Victoria, promising at the same time that they would receive all the lodge as well as all the family practice of the adherents of the fraternal societies. It is most gratifying to learn that there was not one response to this appeal from any single practitioner either in British Columbia or the entire Dominion of Canada. About the first of last December an agreement was drawn up and signed by every physician in Victoria agreeing to stop all lodge work, and the resignations of all doing this work were sent in. No sooner were these resignations handed in than it is asserted on the part of one of the most respected and influential practitioners in Victoria, that two of their number began to do the combined lodge work in the city, which is said to affect about two thousand persons. The members who remained true to their agreement then refused to consult with the two practitioners cited. One was expelled from the Victoria Medical Society; but otherwise, they are accorded their hospital privileges as formerly. The controversy between the physicians and the lodges is exciting a great amount of attention in Victoria, and every meeting of the fraternals is crowded with members. Altogether there are twenty-one lodges in the city; and the societies were paying the doctors about $4000 a year for looking after the health of something like 2000 members. The struggle is said to have beeen precipitated by the fact that all the lodge work was being done by a few practitioners. From present conditions it appears that the doctors are getting the best of the fight, as the lodges cannot import any outsiders, because none have applied, and because the medical act of the province requires that any one going to practice in British Columbia must take the examinations of the Medical Council of that province.

Ontario.

CIRCULAR RE TUBERCULOSIS.

The provincial board of health of Ontario has just issued a circular to physicians and local boards of health on the prevention of tuberculosis at the instance of the committee on epidemics of the provincial board. It states that all inmates of provincial institutions who are affected with this disease should be isolated in wards set apart for such patients, and not be permitted to associate generally with other inmates; that all rooms and wards occupied by consumptives when they become vacant, shall be immediately disinfected. That all individuals affected with tuberculosis and living in private families should be isolated as much as possible from the other members, and that especial care be taken to destroy their expectoration. The circular further urges that local boards of health establish rules for the notification of cases of tuberculosis to the local medical health officer. The medical health officer of any municipality should have a knowledge of the number of cases of tuberculosis therein. On notification of a case the local medical health officer will supply the physician with printed rules for the benefit of the other members of the household for their protection, and thus a campaign of education will be instituted in the province, which if followed up diligently by the local boards of health, will result in much advantage in the way of prevention. The circular also contains a copy of the act passed at the last session of the local legislature, respecting the establishment of municipal sanatoria for consumptives.

LONDON LETTER.

The British Medical Association.

(Continued from p. 511.)

SANATORIA FOR CONSUMPTIVES.

Dr. Nathan Raw, medical superintendent, Mill Road Infirmary, Liverpool, before the Section of State Medicine, said that the whole civilized world is now aroused to the fact that tuberculosis may be stamped out by proper precautions and treatment. Whatever is done, however, must be on a sensible and comprehensive scale, as a disease which kills 60,000 people a year in Great Britain alone can not be lightly considered. As we now know tuberculosis to be a parasitic disease, we have the power to eradicate it. As a communicable diseasee, it is transmitted chiefly through the sputum of consumptive persons, by tuberculous meat and by milk from tuberculous cows. The two latter causes are being rigorously dealt with by health officers and should soon be removed. The first cause, however, is the most difficult of all to deal with. Patients attacked by tuberculosis are looked on as hopelessly ill and are nursed and pampered, carefully cared for in rooms with poor ventilation, and consequently provided with the best conditions for the growth and multiplication of the tubercle bacilli. When these delusions regarding consumption are dispelled, the more fortunate classes will certainly co-operate with the health authorities in any measure they may adopt for eradicating tuberculosis, but the working masses of the population will have to be not only educated but forced to take the necessary measures, and this will have to be done at the expense of the public. The Local Government Board of Liverpool, upon Dr. Raw's suggestion, have provided a most excellent site for a sanatorium 650 feet above the sea level on the banks of the river Dee, easily accessible from Liverpool. This sanatorium will be reserved for the early cases of tuberculosis and no patient will be admitted without a careful medical examination and certificate. The advanced cases have been carefully removed from the general wards of the infirmaries and segregated in consumptive wards, and careful precautions instituted against infection. The working non-pauper class of the community should be provided for by the municipalities, which should erect a sanatorium in a suitable district for these patients. Private enterprise, charity and philanthropy will continue to provide treatment for a few, but tuberculosis must be dealt with in a general way by the corporations which have the custody of the public health in their keeping. The health authorities must do everything possible to prevent the disease among the working classes, but they should also have the means of cure, and the only cure known at present is fresh air and sunlight in a proper sanatorium. In a few years it will be difficult, if not impossible, for a consumptive person to find employment, as public opinion will then have been so awakened to the possibilities of danger from infection that those employed in factories, workshops and offices will object to the presence of consumptives in the same room. When this happens, some provision must be made for their cure, and the proper authorities to deal with this problem are the county councils and municipalities, as the question is too large and general to be left to chance philanthropy and charitable institutions.

STERILIZED HUMANIZED MILK FOR INFANTS.

Dr. F. Drew Harris, medical officer of health, St. Helens, read a paper before the same section on "The Supply of Sterilized Humanized Milk for the Use of Infants in St. Helens." He first considered the prevention of diarrhea, which, in his opinion, occupied a very prominent position among the diseases of early infant life. Diarrheal diseases are especially prevalent among bottle-fed children. During the past five years in St. Helens 81 per cent. of the children under six months who have died were bottle-fed. The author, impressed with these facts, secured a small house and initiated there the municipal sterilization and distribution of milk. The depot was opened on August 8, 1899, and in a short time over eighty children were on the books. At present more than 140 are being fed. The mothers are each given a basket containing nine bottles with the requisite amount of milk according to the age of the child, and are requested to bring the babies once a week to be inspected and weighed. The results are difficult to state with accuracy, owing to the short time the method has been in use, but it may be said that the death-rate among those who have used the sterilized milk was 103 per 1000, as compared with 157 per 1000, taking the borough as a whole. Judged on an average of the past eight years, over sixty infant lives have been saved by this means in St. Helens alone.

DOES SEWAGE TREATMENT DESTROY PATHOGENIC GERMS?

Dr. A. C. Houston opened the discussion on this subject and confined his remarks wholly to bacterial filters. In nearly all cases the size of the particles in bacterial beds is such as to preclude the possibility of the mere mechanical separation of the germs. When sufficiently fine material for this object is used, the filters usually, and almost invariably become choked and useless. In general terms it may be stated that the mechanical separation of the micro-organisms in sewage by the use of bacterial beds is virtually impossible. From the epidemiological standpoint, sewage which has been treated in sewage works is almost if not quite as dangerous as when it left its original objectionable source. He thinks that the possibilities of isolating the typhoid bacillus from ordinary sewage are so remote as to be almost infinitesimal. Nevertheless two microbes indistinguishable from the bacillus typhosus were isolated from the fresh sewage of the Homerton Fever Hospital. In February 1898, when the author commenced his bacteriologic investigations of crude sewage and sewage effluents, for the London County Council, he was impressed with the importance of selecting one or more micro-organisms in the crude sewage and then tracing the fate of these microbes during the biological treatment of the sewage at Barking and Crossness. Bacillus coli and bacillus enteritidis sporogenes were selected for this purpose and the result was that there was no material or constant reduction in the number of spores of this pathogenic anaerobe in the effluent as compared with the raw sewage. The author has also carried out some preliminary experiments on the vitality of the cholera vibrio and staphylococcus pyogenes aureus in unsterilized sewage and considers that the death of these microbes is certainly a question of days and probably of some weeks. The lesson to be learned from these experiments is, that the element of time or delay is an all-important factor, and that it is doubtful if any bacterial process in practical operation at the present time treats or detains the sewage for a sufficiently long period to allow of the complete destruction of all pathogenic germs by bacterial agencies.

PREVENTION OF TUBERCULOUS DISEASE.

Dr. Henry Kenwood, assistant professor of public health, University College, London, opened the discussion on "The Action which Can be Taken by Local Authorities for the Prevention of Tuberculous Disease, Apart from the Control of Milk and Meat Supplies." He first reviewed briefly the various measures available which do not necessarily entail a scheme of voluntary or compulsory notification. The first measure was improved sanitation and he considers that the energies of the profession should be directed toward the prevention of over-crowding, securing healthy homes for the lower classes, and improved general scavenging. To these ends oft repeated and systematic sanitary inspection of the tenemented or lodging houses is imperative. It is noteworthy that in the London sanitary areas the more over-crowded groups have higher death-rates at each age period than the less over-crowded, showing what a close relationship exists between phthisis and the housing of the poorer classes. He then discussed educational measures. The dissemination of knowledge must be accomplished largely through individual initiative. A handbill left at the door of the poor man's house is not sufficient for this purpose. He ascribes the very rapid and fairly general diffusion of the education of the masses, which doubtless now exists, to the newspapers. The annual meetings of the British Medical Association, the Sanitary Institute, the Royal Institute of Public Health, the National Health Society, the National Association for the Prevention of Consumption, and the Church Sanitary Association, are all doing much to educate the public on matters of public health, but the greatest means of education lies in the schools, which should instruct the future generation in the elements of hygiene, healthy infant-rearing, and of infection and its prevention. Every means of educating the population must be brought into use by sanitary authority, and this education must be direct, convincing and practical. The registrar of deaths should advise the medical officer of health of all deaths from phthisis as soon as possible after registration, so that the proper disinfection may be made and advice given. Medical men and nurses should be asked to co-operate in advising and directing the necessary preventive measures in infected households. The employment of consumptives in the cooking or selling of food should be prohibited so far as possible. Isolation hospitals and sanatoria should be provided for those already attacked by the disease and notification of infected houses should be made without fail to the local boards of health. The intelligent section of the public realize the enormous benefits which would accrue to the community from a reduction in the prevalence of phthisis to the lowest attainable limit, and the past two years have witnessed an almost invariable recognition of the infectious nature of the complaint, and a readiness to adopt the necessary measures of precaution. The public is prepared to receive the advice and help of the medical profession and the measures which they adopt will not only operate against consumption which is so dreaded, but will at the same time raise the standard of general health, so that the crusade against consumption will be indeed a crusade against the disease.

RURAL PHTHISIS.

SIR H. B. BEEVOR, M.D., physician to King's College Hospital, London, delivered an address on "Rural Phthisis and the Insignificance of Case-to-Case Infection." The death-rate is the best and most reliable index of the incidence of phthisis and a primary indication of epidemic or infectious agencies in any disease is afforded in the irregularity of incidence in that disease. In the County of Norfolk there is a remarkable family likeness in local constancy. The death-rate from 54 series of statistics is alike in each decade, but varies in different decades. This seems to be cogent evidence of the insignificance of case-to-case infection. The author sums up by an adaptation of the remarks of Dr. Andvord, of Sweden, in this regard by saying, "In like places the special constancy of lung tuberculosis does not point to any place among infectious illnesses."

COTTAGES IN RURAL DISTRICTS.

DR. J. S. TEW, medical officer of health for the West Kent Combined Sanitary District, introduced the discussion on "The Provision of Cottages in Rural Districts, and its Bearing Upon Public Health," in which he called especial attention to the urgent necessity for better cottage accommodations in many rural districts, to the desirability of rural district councils undertaking the building of cottages, and to insufficient air-space in crowded cottages which, in his opinion, contributed largely toward lowering the vitality of the occupiers and toward the high death-rate among the working classes from measles, whooping-cough, phthisis, etc., which are usually nursed at home.

DIET IN RELATION TO CANCER.

DR. JOSIAH OLDFIELD, of London, stated that cancer is not a disease which is caused by flesh-eating *per se*, since it has not been found to be largely prevalent among the early hunting tribes who lived almost wholly upon the products of the chase; the disease was increasingly prevalent in England among the aristocracy, despite the fact that the aristocracy of to-day ate less meat than in the time of Queen Elizabeth. The contention of Sir W. Banks that the cause of cancer was the nitrogenous element could not be upheld. Cancer, however, was found more prevalent among the classes who indulge in generous living than among those who live more hardy. Again, the topographical distribution of cancer in temperate climates is along the beds of sluggish rivers. The theory propounded "suggests that under certain circumstances there is present in the cell envelope, and closely connected but not actually transformed by a complete metabolism into cell substance, food matter partly broken down and ready to still further break down, and thus to form a fit pabulum for low organisms. The position of the food, mingled up, as it is, with the cell substance throughout the body, or certain parts of the body, renders it possible only to be utilized by organisms which can invade the cell itself, and which, by the position of their progress in search for their food, must be necessarily pathogenic, and must possess the essential type of invading cell from cell and of penetrating cells throughout and permeating them and passing through them, leaving behind those parts of each cell which were essentially vital, and destroying far ahead those parts of the cells which consisted of that food matter described. The presence of food half assimilated, and thus spread throughout the cells, and the search for and the feeding upon this food by low organisms that would thus necessarily invade, half destroy, and rapidly spread on to other cells without actually destroying all the cell life as they progressed, gives us a picture very like what a malignant growth is in its characteristic features."

CANCER IN EAST ESSEX.

DR. GEORGE MELMOTH SCOTT, Witham, made a report on the mortality from cancer in Chelmsford and Maldon, East Essex. About 1000 deaths from cancer occurred in these two unions between 1871 and 1898. The number of deaths by decades was increased from 6.36 in the first to 7.73 in the second and 8.41 in the third decade. In the first decade 100 women died from cancer, to 51 men; in the second the proportion was 100 to 61, and in the third 100 to 83. Although there has been some actual increase in the number of deaths, the author's impression is that the cause of the apparent increase may lie to some extent in more careful diagnosis. In the author's inquiry he endeavored to test the truth of Dr. Haviland's theory, which postulates that: In the counties having a high mortality from cancer, the tributaries of the large rivers rise from soft marshes or easily disintegrated rocks; that these rivers invariably flood their adjacent districts during the rainy season; and that the districts characterized by the tertiary and more recent clays and other retentive soil have a very high mortality from cancer. The author concludes that the cause of cancer must be looked for in some other direction than in an alluvial and clayey soil subject to floods, because the disease is less common in the county of Essex with its clay soil and numerous estuaries than it is in England as a whole; that, although the unions of Chelmsford and Maldon contain an excessive proportion of marshy land and estuary, their death-rate is below that of the county of Essex; that those parts of the two unions which include the greatest extent of muddy foreshore, creek and saltings have a mortality below that of the two unions taken together, and that the disease is not especially prevalent in those places situated on the banks of the fresh-water rivers.

PRESERVATIVES IN FOOD.

DR. ALBERT S. GRÜNBAUM, Assistant Lecturer in Physiology, Thompson-Yates Laboratories, University College, Liverpool, presented a paper on "Food Preservatives and Coloring Matter in Food, with Reference to Foreign Laws and Conditions."

The enormous extent to which food preservatives are now used, the abuses to which they are put, and the injuries which they may cause, make stringent and definite legislation on the subject necessary. The law is at present too vague and narrow and the magistrates too ignorant for much progress in this direction. Laws requiring any trade to have consideration for public good may reduce but will not destroy profit. He then takes up the subject of milk and wines and beers and details the objection to preservatives and to coloring matters. The public is chiefly to blame for the use of coloring matters, as if brightly-colored foods could nowhere be obtained, the uncolored foods would be bought. The use of preservatives in milk, cream, etc., rests chiefly with railway companies and ice-vendors, and is due to the scanty use of ice in England. He considers railway companies the chief offenders and suggests that injustice may be done by legislating too hardly for the purveyors of perishable foods, unless at the same time rational treatment of the foods themselves is required of their carriers.

HYGIENIC ASPECT OF THE USE OF WATER GAS.

DR. JAMES CHARLES MCWALTER, of Dublin, considered the increasing use of water gas by the gas companies to be a source of distinct danger to the consumers. The dangers were very considerable for more than one reason. The leaking of the mains, the leakages from the house fittings, and the occasional omission to turn off the taps were sources of great danger. Carbon monoxid, together with the other gases leaked through the leaden and composite pipes by osmosis, and water gas might get through at a greater rate than the other constituents. The introduction of considerable admixture of water gas with coal gas in towns had been followed by an "immediate, enormous, and proportionate increase in the number of deaths ascribed to carbon monoxid poisoning." The saturation of the ground air, in towns supplied with water gas with carbon monoxid, was one of the causes of the endemicity of such diseases as enteric and epidemic cerebrospinal meningitis. The official gas testers should return the proportion of carbon monoxid in the gas, and legislative measures should be adopted to prevent the gas companies mixing without warning any proportion of water gas with the coal gas which they supplied. Some more convenient and accurate means should be devised to ascertain the degree of minute proportions of the gas, than the method by absorbing it with cuprous chlorid.

BACILLUS DIPHTHERIÆ IN MILK.

DR. J. W. EYRE made a report "On the Presence of Members of the Diphtheria Group of Bacilli Other Than the Klebs-Loeffler Bacillus in Milk," based upon the observations at the Bacteriological Laboratory of Charing Cross Hospital, London, from which he concludes that several groups of bacilli, exhibiting segmentation, metachromatism and clubbed involution forms are occasionally present in milk; that the bacilli of these groups agree in resembling the bacillus diphtheriæ to some extent, but are capable of being differentiated from it and from each other; that these bacilli arrange themselves according to their color production into three well-defined groups, which are characterized by the coloration of the colonies themselves without the nutrient medium being affected, and by the infiltration of the medium by a pinkish color, the colonies themselves being only slightly chromogenic; that the members of these three groups are non-pathogenic, and that it is practically impossible to diagnose the presence of the true bacillus diphtheriæ in a sample of milk by microscopical tests alone, but that the identity of the bacillus can be established only by careful consideration of its biological and pathogenic characters.

Correspondence.

Tetanus Neonatorum and Hot Moist Climates.

KEY WEST, FLA., Aug. 22, 1900.

To the Editor:—In reply to your query as to the correctness of report of four cases of tetanus neonatorum and one case of tetanus (adult), the result is perfectly correct. I can assign no reason for the high percentage of tetanus, unless it be that tetanus is far more prevalent in warm and moist climates than in cool and dry ones. This I read when I was a student about forty years ago, and my residence here for over thirty-five years confirms it. A very significant fact, lending aid to this explanation, is that although by far the large majority of the cases of tetanus in the adult are traumatic—the adult case reported was from traumatism, a splinter under the finger-nail—yet quite a large number of cases are idiopathic.

While the old women and the midwives attribute tetanus neonatorum generally to some supposed traumatism of the umbilical cord, yet from my experience, I believe that a far greater number of these cases are idiopathic. Recently in my practice a child was born with stiff jaws, and unable to take the breast. This developed into tetanus neonatorum, with tetanic convulsions, opisthotonos, etc. The delivery was an eutocia, the mother a multipara. Had the delivery been a dystocia, the mother a primipara, or the child abnormally large, there might have been a presumption of trauma from pressure or strain on the spinal cord, or from some other traumatic cause; but the origin in this case was either prenatal, congenital, or, at least, synchronous with birth. The mother could recall no prenatal injury to herself. I therefore confidently believe the cause to have been idiopathic. The child died nineteen days after birth. I should like to emphasize some facts, which I am afraid are not as well known as they should be; that tetanus is a self-limited disease; that its natural run is about three weeks, and that there is an element of hebdomadality about it. I have attended hundreds of cases of tetanus neonatorum, and have had only seven recoveries. I do not claim them as cures.

With reference to tetanus traumaticus, of course, the previous history points to trauma of some character.

Now, as to your last enquiry, "Why has Key West, Florida, such a high percentage?" The high percentage obtains not only in Key West, but also in Cuba and the entire West Indies, and I believe universally in the semi-tropics and tropics, not only of the Western, but the Eastern Hemisphere as well, owing to the action of the moist atmospheres, with sudden and great alternations of temperature. We have seven months of continuous hot weather, with the remaining five nearly as hot. Except during the prevalence of a "norther" I have known it here as hot in December or January as in July or August. In the temperate zones you have three very hot months (hotter than any of ours), six pleasant months, and three very cold months (colder than any of ours). Our climate is always moist and enervating, yours for nine months bracing, and dry nearly the whole year. You have better digestions and better foods, especially. Your bodies are well nourished. Your *vis medicatrix* functionates well. Your vitality and resisting powers are great, ours are small. Your faces and red and round, ours pale and thin. Stand on the principal streets of Chicago or on Broadway, New York and then come and stand on Duval street, Key West, or on Calle Obispo (the Broadway of) Havana, Cuba, and compare the difference of the appearance of the people who pass, and I think you will readily conceive why the percentage is high, especially in this disease whose seat is in a portion of the nervous system.

Very respectfully,
J. W. V. R. PLUMMER, M.D.,
City Health Officer, Key West, Florida.

[Under "Florida News," last week, p. 505, we published the showing made by Key West in their health report, which gave four deaths from tetanus neonatorum, equaling 14 per cent. We wrote the health officer for an explanation of the peculiar occurrence and received this reply. The doctor, in considering the cause of tetanus, evidently overlooks the fact that there is such a thing as a bacillus tetani. He lays considerable stress on heat and moisture as etiologic factors in the disease, of course these are the two essentials in the propagation of the bacilli.—ED.]

Castor-Oil in Neuralgia.

OGDEN, IND., Aug. 25, 1900.

To the Editor:—I read with much interest Dr. Moyer's article on castor-oil in neuralgia, and also the article by Dr. Caldwell on the same subject. I have a patient under my care who has suffered for years with supraorbital neuralgia. She has been under the care of various physicians, who have prescribed cod-liver oil and other restoratives, and probably the entire list of anodynes and analgesics. The patient having a history of chronic constipation I began the use of Dorsey's solution, but the attacks returned with their usual severity and regularity. About two months ago I began the use of the following:

℞. Olei ricini
  Glycerini āā ....℥iii
  Tincturæ opii camphoratæ.............℥iv
M. *Sig.* *Teaspoonful at bedtime.*

I have given the above every day since beginning the treatment.

The patient has had but one attack since, and that a very mild one. Her general appearance is much improved, and her chronic constipation is a thing of the past.

The question is whether the theory of Prof. Gussenbauer is tenable, or whether we do not have in castor-oil a restorative agent hitherto unrecognized.

Alva W. Knotts, M.D.

Alleged Army Medical Abuse.

Washington, D. C., August 21, 1900.

To the Editor:—We have been reading recently in the daily press and medical journals about the shortcomings of the British Army Medical Department in Southern Africa. During the active progress of the war we heard nothing but words of praise for the devotion to duty of the Medical Department and its foresight in providing all that was needful for the care of the wounded hundreds of miles from the base of supplies. General officers, themselves wounded, testified to the admirable management which brought their wounded men from the field and transported them in comfort to the base hospitals at Cape Town. Kipling has told the story of one hospital train on its way to the front and thence back to the general hospitals with its load of disabled men. His brilliant description of the return trip conveys a sense of the restfulness and comfort enjoyed by the men who had been gathered up from the battlefield. An air of solicitude for the comfort of the sufferers pervades every sentence of the story and everything which the most judicious provision would be likely to call for as being needful appears to have been at command. Eminent surgeons from civil life were sent out ostensibly to give the benefit of their wisdom and experience to their military confrères, but in reality as inspectors on the part of the British public; and their words have been words of commendation for the excellent work of an overworked department. All this we supposed to be fact and we were proud of the record which our British brethren had made under trying conditions; but a very estimable gentleman, having no experience of war and its methods, visited Cape Town and exposed the shortcomings of the medical department. The daily press spread his views before the public, and now an investigation is in order which will no doubt redound to the credit of the department, for we can not suppose that so many thousand sick and wounded men came back to England from South Africa during the past year without exposing the failure of the medical department to do its duty, if there were such a failure.

Our own Army Medical Department has now become the subject of adverse criticism, which was brought to my attention by some editorial remarks in the last issue of The Journal under the heading "Alleged Army Medical Abuse." From reading the official reports of medical officers in the Philippine Islands, I was under the impression that our troops serving there were very well cared for. On the close of active campaigning some months ago, the army was broken up and distributed for garrison duty in a large number of towns, seaport and inland. Good quarters were provided for them, with plenty of good food and purified water supplies. Under these favorable conditions the sick-rate became reduced to about 8 per cent. of the command. Each detachment or garrison has its local hospital for emergency or trivial cases. There are well-equipped base hospitals in each district for the care of cases of greater gravity, and for the relief of these there are hospitals in Manila with a capacity of about four thousand beds, including a convalescent hospital on Corregidor Island in the mouth of the bay. For the transportation of cases from seaport towns which have no railway connections, the hospital-ship *Relief* does excellent service. It was, therefore, with considerable surprise that I read the editorial in your last issue. On making inquiry, I found your remarks to be based apparently on press despatches from Washington, D. C., dated August 7, 1900, which state that within two days after her arrival in Manila a lady from New York discovered the impoverished condition of the medical department and promptly reported her discoveries to the Secretary of War and other prominent persons. Much stress appears to be laid on the want of sheets, for the lady is represented as having appealed for 500 sheets for immediate distribution. How the discovery of this want of sheets was made is not stated in any of the published articles I have seen. You are kind enough to say that: "In the matter of sheets, which seems to be one of the special points of criticism, there might readily be an apparent defectiveness and yet no very serious hardship to anyone, certainly not to a seasoned soldier, convalescent." You will be pleased, therefore, to know that even this hardship was not necessarily entailed upon any of our sick soldiers in Manila. If this lady had inspected the medical supply depot in that city she would have found a plentiful stock of sheets, as compared with the 500 for which she appealed. From January 1, 1900, till the present time, there have been sent to Manila for hospital use 79,500 sheets, and on August 9, 1900, there were on hand for issue no less than 23,940.

I need say no more about the "alleged army medical abuse."

Respectfully, Charles Smart, M.D.,
Lieut.-Col., Deputy Surg.-Gen'l, U. S. A.

Rambling Notes of a Roving Doctor.

Paris, August, 1900.

PARIS EXPOSITION.

To the Editor:—I have a clipping from an American newspaper regarding the Paris Exposition, in which the writer claims that in the great art gallery, where the different nations have their pictures on exhibition, the United States eclipses them all. Before I read this I had visited and studied with some care this collection, and I had put the United States in about the ninth place, as compared with the works of other countries. We have, it is true, a few good pictures, especially good portraits, but the collection as a whole does not do us credit as a nation possessing a high order of artistic skill. While, I believe, it was understood that France was to have 45 per cent. of the space alloted to exhibitors, she has managed the matter so much to her advantage that she has appropriated at least three-quarters of all the desirable space.

"LA VILLE DE PARIS."

"The Ville de Paris" contains, in my opinion, the most valuable and instructive collection of any one building on the grounds. Here, under one roof, all the best things that Paris has produced may be seen. The engineer can see specimens of nearly every style of work that he will ever be called upon to perform. Systems to drain cities and supply them with pure water, that before its filtration was reeking with germs, are illustrated. Miniature streets are shown, in which different kinds of pavement are exhibited, and their cost and durability are given. The chemist can look into a laboratory where are produced many of the articles that belong to his profession, and can see the appliances used in their production. The physician can see here a hospital bed such as was in use at Hôtel Dieu at the end of the eighteenth century, where four men occupied one small couch, two of them having their heads in opposite directions. In the next room is a modern hospital cot, occupied by a single patient, whose surroundings are so airy and comfortable that it would seem a luxury to take his place and play the rôle of a sick man.

One entire room is occupied by appliances for the study of germ life, their cultivation in different media, and their microscopic examination. The veterinarian can see the morbid changes that take place in the organs of the cow, the sheep and the horse. There, too, is the incubator where eggs are hatched, and the incubator in which prematurely born children are kept alive and made to grow. The policeman and detective will be interested to see how Alphonse Bertillon photographs a criminal so that no disguise that he may afterward assume is able to obliterate his identity.

HYGIENIC BUILDING.

In this building I expected to find much that would interest me, but in this I was a good deal disappointed, for though much of what I saw was very fine indeed, the whole building was full of things that were designed only to grace the residences of the very rich. There were marble basins, marble closets, marble bath-tubs, all placed in beautifully furnished rooms, where the drainage was faultless, but nothing in the way of an improved method of health appliance for the houses in the small towns or villages. Gracing one of the entrances of this building is a statue of Pasteur. Below and around this is a large circular glass case that contains the chemical and bacteriological appliances that he used to demonstrate his first discoveries in these branches of science. There are the flasks in which he illustrated the fact that acid fermentation was caused by the development of living germs, and by which he disproved the long-held doctrine of spontaneous generation of bacterial life. The side walls of the entire entrance are covered with test-tubes still having in them the cultures that he himself made. All these appliances are of interest only because of their association with their great master, but are all sadly out of date as compared with those used at the present time.

PASTEUR INSTITUTE.

One of the most richly endowed of the modern institutions in Paris is the Pasteur Institute. A quarter of a century ago, when I saw the first of this great Frenchman and his work, the quarters that he occupied were most humble and unpretentious. To-day it occupies both sides of a wide street, and the buildings seem to have been erected with a sentiment that was blind to the expenditure of money. On one of those tropical mornings that have followed each other with unprecedented regularity in Paris this summer, I visited this institution to witness again some of its work. At 10 o'clock the great crowds that are being treated with antirabic serum began to gather in the large hall set apart for their reception. These patients were as mixed specimens of humanity as one could well imagine. People from every part of France, soldiers and civilians from all parts of Asia, made up a motley crowd, attracted to this spot by a common impulse, which was to have arrested in its progress one of the most terrible diseases that affects the human race. New patients are always examined before the regular treatment of the older cases is begun. On the morning of my visit there were 15 new cases, but as madness of the dog was proved in only three of these, the balance were sent away and kept under observation. Two women had been bitten by men, and in one of these cases at least the man was drunk and not mad. One hundred patients were given 150 injections by one man in just 45 minutes. In spite of the Pasteur Institute and its antirabic treatment, two men have died in Paris during the first 20 days of July of hydrophobia. In Austria and Germany the smallest dog is not allowed on the street unmuzzled, but in Paris they run at large unmuzzled, and bite scores of human beings every day. After the patients were all treated I took a stroll through the institute, having for my guide T. B. Tupille, who was the first patient treated by M. Pasteur for hydrophobia. This accident has immortalized him, and he is probably prouder of his fame than Pasteur ever was of his own. In front of the main building stands a bronze monument that represents a terrible encounter between a boy and a mad dog. The boy was unarmed, but, slipping a wooden shoe from his foot, he dealt the beast a blow that caused his death. Tupille shows with pride the scars upon his hand that he received in the terrible encounter. It is the time of the summer vacation, and the instructors are away at the seaside enjoying their holiday rest. I saw only half a dozen men at work in the different laboratories, and four of these were from Boston, and whose enthusiasm even a temperature of 90 in the shade could not obliterate. The great library, adorned with busts of Pasteur, Rothschild and Baron Hirsch, was occupied by a single man, who seemed so occupied in his efforts to keep cool that books had little attraction for him. It was the wish of Pasteur that his body should not be interred with the immortals at the Pantheon, but in a crypt beneath the building where he had finished his life work. And there it rests, beneath a monument of exquisite beauty, and though less grand and gaudy than the one a little way off at the Invalides, where rest the ashes of the great Napoleon, each marks the spot where lies one of "the immortal few that were not born to die"; but while the immortality of the one was achieved by the sacrifice of millions of his kind, the other owes his undying fame to the fact that he was the benefactor of his race and the savior of many human lives. Outside of France the efficacy of the serum treatment of hydrophobia is generally recognized as one of the greatest achievements in medicine during the century just closed. While no one here now opposes the remedy with the vehemence of the late Professor Piter, yet I am convinced that the faith in this agent is far less universal in the land of its nativity than it is in foreign countries.

CLINICS AND OPERATING-ROOMS.

When I arrived in Paris this summer I went at once to the Broca to see Dr. Pozzi. He showed me all through his gynecological pavilions, which are perfect models of their kind, and invited me to be present at some operations that he was to do after a few days. I expected when I came to Paris to find the clinics and operating-rooms so full that one could see nothing. I have been here now two months and during that time Dr. Graham, of Chicago, and Dr. Brigham, of San Francisco, are the only American physicians I have seen in a Paris hospital. I find a good many South Americans, but the English-speaking races are not here. At the Exposition you find more Germans than any other class of foreigners, and though a good many Americans come here for a few days, they cut their stay short and go away to Switzerland and Germany, where they are not robbed as they are in the French capital.

INTERNATIONAL MEDICAL CONGRESS.

In many respects the meeting must have been a disappointment to the French profession. In numbers it was two or three thousand less than the Moscow Congress of 1897. Its social element was a sad disappointment to the visiting members. While this was partly due to the tragic death of the King of Italy, still had all the program been carried out it would not have come up to the expectations of those who were so magnificently received and so royally entertained in Moscow. The paper which was most warmly received was that of Dr. Abraham Jacobi. (See The Journal, August 18, page 445.) Although Americans were in the minority, still, in the surgical section, the mechanical aids were to a very large extent devised by American surgeons. W. S. Caldwell, M.D.

Medullary or Subarachnoid Cocain Anesthesia.

Chicago, Aug. 26, 1900.

To the Editor:—At your request I submit the following report on "medullary or subarachnoid cocain anesthesia:"

During the meeting of the International Medical Congress at different times, Prof. Tuffier invited members of the congress to witness his operations, particularly laparotomies under subarachnoidean cocain anesthesia; the details of the experiments and advancements in this method of anesthesia are best given in the words of Tuffier himself, which I take the privilege of quoting from a brochure—which he kindly gave me—of an article that appeared in the *Semaine Médicale,* May 16, 1900. In addition to the statements made in that article, he announced at his demonstration that he had used the anesthetic in 130 cases and did not have a fatality, complication or unpleasantness in any one of them. That the analgesia was complete admitted of no question, as we witnessed four major operations, three laparotomies, including an abdominal hysterectomy and a nephrectomy. The hysterectomy was made on a woman, I believe he said, 64 years old. All of the patients were perfectly conscious during the operation and none complained in the least of pain. There was some nausea and vomiting. Prof. Tuffier says:

> After numerous experiments since November 9, 1899, I have made use of surgical anesthesia induced by the in-

jection of solutions of cocaine in the lumbar subarachnoid space. In a previous communication I mentioned the works of Franck, Bier, Sicard and Sedlovitch, and I also published the results of my experiments. In these communications I also showed the facility and innocuousness of this method of anesthesia. The same was confirmed in a thesis by my interne, Mon. Cadol. I herewith give the precise technique which I have adopted. My operations have been on the lower extremities, perineum, rectum, abdomen, external and internal female genitalia and male genitalia. In all of the sixty-three cases I obtained absolute analgesia and the cure of my patients without early or late complications. The field has now increased and includes intestinal, gall-bladder and kidney operations, nephropexies and nephrectomies. (He has not performed any operations above the diaphragm.) I believe this method to be practical and I will insure success to whoever follows my method of procedure.

I use for these injections Pravaz' syringe, admitting of sterilization. (Hypodermic with asbestos piston.) The needle must be sufficiently long to penetrate easily the space between the skin and the subarachnoid space. This interval varies in length, according to the muscular development and obesity of the patient. The needle must be of platinum. It must be easily sterilized, and be 9 cm. long. External diameter must be 1.1 mm.; the internal diameter .8 mm. It must be solid, so as not to bend when it comes in contact with the vertebral column. Its end must have a short bevel.[3] I employ a 2 per cent. solution of cocaine. This solution must be sterile and recent; old solutions must be discarded. This is important.[4] The fluid injected must be carefully sterilized. I prepare my solution as follows: The solution is exposed to a temperature of 80 C. in a water-bath for fifteen minutes, then it is kept in a temperature of 38 C. for three hours; it is again brought to a temperature of 80 C., then allowed to cool to 38 C. This operation is repeated five or six times in succession. It assures a perfect sterilization; the anesthetic properties of the cocain are not altered. The operative technique is as follows[5]: The patient is in the sitting posture, both arms carried forward. The field of injection is thoroughly asepticized. Locate the iliac crests. An imaginary line connecting these two crests passes through the fourth lumbar vertebra. By injecting beneath that line you penetrate the medulla canal. As soon as you have located with the left index finger this spinous process, tell the patient to bend forward so as to make a big bag. This bending forward causes a separation of 1.5 cm. between the vertebra on which you have your index finger and the subjacent vertebræ. Then it is always wise to tell the patient, "I am going to stick you with a needle; you will feel some pain, but do not move."[6] Make the injection with the right hand. I insert the needle to the right of the vertebral column. about[7] 1 cm. from the line of the spinous process. The needle goes through the skin, through the subcutaneous cellular tissue, through the lumbar aponeurosis, through the muscles of the sacrolumbar region, and penetrates into the lamellar space, and at last penetrates into the spinal canal. As soon as the needle is in the subarachnoid space it meets no resistance, and from it escapes a clear, yellow fluid. This fluid is the cerebrospinal fluid, and escapes drop by drop. The surgeon must never inject a solution of cocain before he has seen the cerebrospinal fluid escape through the needle. After the surgeon has seen this fluid escape through the needle he attaches to the needle a syringe containing 1 c.c. of a 2 per cent. solution of cocain. The injection is made slowly; it should be completed in one minute. The dose injected should not exceed 15 milligrams of cocain.[8] I always employ a 2 per cent. solution. The injection terminated, I rapidly remove the needle and close the needle-puncture with sterilized collodion. Note the precise minute at which the injection is terminated, and then wait. The patient can be questioned as to the subjective sensation which he experiences. After a certain lapse of time, which in our observations varied according to the subjects from about four to eight or ten minutes, the patient would complain of a tingling sensation and numbness of the feet. This numbness extends to the legs. You can now begin to operate. Gradually a sensation to pain and heat disappears. Contact sensation persists. Toward the last the motor system may be affected. From four to ten minutes after the injection analgesia is usually complete. Most often it extends to the thorax: occasionally to the axilla. It is not an approximate analgesia; it is complete; it is absolute, so much so that in a thigh amputation we asked the patient to elevate his stump so that we could better secure the vessels. In the course of the operation the patients, when questioned, would say that they felt only a sensation of contact. One of my patients could hear me saw his femur, and told my assistant that he could not tell whether I was sawing his femur or sawing the table. While doing a vaginal hysterectomy one of my patients felt that something was giving away, when the uterus was being removed, but she experienced no pain. In the course of a lumbar nephrectomy the patient, at the close of the operation, asked us if we were not going to soon begin the operation. The duration of analgesia is from one to one and a half hours. It has always allowed me sufficient time to complete the most laborious intervention.

The position which the patient is made to assume during the course of the operation does not at all modify the analgesia. I have thus always been able to employ that posture best suited to the operative procedure. Like under general anesthesia, I have operated in the inclined posture and in the left lateral posture.

The following incident may happen in the course of the puncture: In subjects whose spinal column is deviated, as in scoliosis, the line of the spinous process can only be found with difficulty, and owing to the fact that the vertebral laminæ have lost their normal relations, the puncture may be difficult. This obstacle, however, can be overcome by patience on the part of the operator. If the needle strikes against a vertebral lamina, change the direction of its point either upward or downward, but do not pull it back and forth. This pulling back and forth along the blunt needle may succeed in breaking it. The better thing to do is to remove the needle. Make another puncture higher up or lower down. The solution must be injected in the subarachnoid space. There is only one sign which permits us to affirm that the needle is in the cavity. I mentioned that sign before; it is the escape of cephalorachidian fluid. If blood escapes through the needle it may be fluid blood or it may be blood with an admixture of cerebrospinal fluid. As to the nature of the blood, you can not decide by simple inspection. We repeat the puncture, and we will not inject until we have seen two or three drops of pure cephalorachidian fluid escape.

Can this method of anesthesia be productive of any accidents? I do not know, but basing my opinion upon my personal observations, I can affirm that I have never seen a serious accident. Usually the patients complain of epigastric weight, the feeling of epigastric coldness; they are anxious; they are nauseated; emesis is frequent. These accidents may occur during the operation, a few minutes after the puncture, but they usually occur in the few hours that follow the puncture. These accidents are very frequent. I have noticed emesis 50 times in 63 operations; the vomit is mucous or bilious; it is not abundant; it yields readily to the ingestion of ice. Headache occurs more frequently than emesis. In two-thirds of the cases it is light headache, a simple heaviness. It disappears in a day following the operation. It can, however, be a very severe headache, provoking insomnia, and disappearing only at the end of forty-eight hours. I have noticed profuse sweats, some

---

Note 3—The ordinary needles with very oblique bevel possess one disadvantage. This disadvantage is that the orifice of the needle may only be partially in the subarachnoid space, while the other portion of the needle may be without the sheath, so that the injection may flow partially into the subarachnoid space and partly into the surrounding tissues, so that this needle with a short bevel is what he prefers.

Note 4—In a few of my trials I failed to obtain a complete and perfect analgesia. This failure was due to the fact that I employed an old solution of cocain. The solution was not absolutely limpid. In these cases, by following the unsuccessful injection with a fresh solution the desired result was obtained.

Note 5—In my first case, to make the injection, I used to place the patient in the left lateral position, the thighs flexed on the abdomen and the body bent forward. It has seemed to me that in this position the spinal column is subject to deviations, is subject to flexures, which make lumbar puncture difficult.

Note 6—The patient being forewarned, when the needle penetrates the tissues he does not jerk, and by not jerking he does not deviate the needle from its proper course.

Note 7—When the same posture is used the needle must be inserted perpendicularly from backward forward.

Note 8—If this dose be exceeded, epigastric anxiety is more marked, vomiting is more frequent, but nevertheless even with a large dose I have never observed any alarming symptoms.

dilatation of the pupils, some shaking of the limbs, some rapidity of the pulse; all these accidents have disappeared twenty-four hours after the operation. In 15 cases I noticed an evening elevation of temperature on the day of the operation. This elevation occurred in the absence of any operative complication. On the next day the temperature was normal. In 40 patients I noticed a chill after from ten to fifteen minutes.

Among my patients there were 39 males and 24 females. They varied in age from 12 to 69 years. Sex and age seem to have no influence on this method of anesthesia. I would consider children and hysterical individuals as being poor subjects for this method of anesthesia. I consider it well to put a simple compress over the patient's eyes. Some of my patients objected to being blindfolded.

In closing this I may say that if from one cause or another analgesia was not obtained, this injection of cocain in no wise contraindicates the immediate administration of a general anesthetic, ether for instance. In my first experiments, before I had mastered the technique, it has often happened that I had to etherize the patients after the injection of the cocain. It has seemed to me that it facilitated and made less disagreeable ether anesthesia.

Since my return from Paris, on August 19, I have used this method of anesthesia in three cases, with the following results:

Case 1.—Miss B., Cook County Hospital, aged 22 years; left pyosalpinx, with history of rupture into the intestine. Injection of 15 minims of 2 per cent. solution of hydrochlorate of cocain in the subarachnoid space in the lumbar region on a level with the iliac crests. The needle was easily inserted, the cerebral fluid escaped and about forty seconds were consumed in injecting the fluid after the syringe was connected. The opening, when the needle was withdrawn, was sealed with collodion. The operation was commenced 8 minutes after the injection. Median incision was made; the adhesions were very extensive and firm. It was difficult to separate the tube from the bowel. The wall of the latter was enormously thickened, and I feared that a sinus was present. Careful examination did not reveal one, the tube was removed, the pus sponged out and the omentum drawn over the intestine and pressed down into the pelvis, as the sigmoid was fixed and could not be turned down to protect the abraded surface. The operation was completed by closing the abdomen with figure-8 sutures; no drain. The patient was conscious of the fact that she was being handled, but there was not the slightest pain. She was nauseated and vomited some 6 minutes after the operation began. This retarded the work a couple of minutes. Her pulse at no time exceeded 75, and ranged from that to 60. She did not vomit after the operation. Her temperature that evening reached 102; since then it was normal; no unpleasant symptom has since occurred.

Case 2.—Male, aged 50 years, Cook County Hospital. Varicose veins of the leg; Schede operation. Thirteen minims of cocain. A 2 per cent. solution was used for injection. Anesthesia was complete in 7 minutes. There was some nausea and vomiting during the operation. There was perfect analgesia. The pulse was not accelerated and was strong at all times.

Case 3.—Male, aged 46, Cook County Hospital; sensitive ulcerated stump following amputation for diabetic gangrene. In this case 15 minims of eucain solution were injected. A little difficulty was experienced in getting in between the laminæ. Some nausea and vomiting occurred as with cocain. It was 12 minutes before the analgesia was complete, and there was some return of sensation 10 minutes after the operation was commenced. On the whole it was not as satisfactory as cocain.

I hope that the nausea may be controlled by the addition of atropia to the cocain, and I will try it in my next case. That cocain anesthesia will displace chloroform or ether anesthesia for operations in the abdomen and lower extremities is a question that will take a long period of time to decide. That it will have its special field of usefulness, the same as ether and chloroform, can scarcely be doubted, even though our experience is now so limited.

I beg to submit this report, and will follow it with others as the range of experience increases, and appreciate the compliment paid me in the request for it. Respectfully,

J. B. Murphy, M.D.

Deaths and Obituaries.

Ernst Schmidt, M.D., died at his residence in Chicago, August 26, aged 70 years. He was one of the most prominent medical men of Chicago, had been for thirty years chief of the consulting staff of the Alexian Brothers' Hospital and for many years consulting surgeon to Michael Reese Hospital. He was graduated from the University of Würzburg in 1852, but was obliged to leave Germany on account of his prominence in revolutionary matters. He settled in Chicago in 1857 and soon established himself in active practice. He was always earnest for reform, as was shown by his revolt against established government in Germany, his prominence in the "underground railway," his defense of the "anarchists" in 1886, etc. He had a large practice, but on account of long-standing kidney disease had virtually been retired for three or four years.

Franklin Booth, M.D., an old and much esteemed physician of Elmhurst, Long Island, N. Y., was run over by an electric car August 18. He was taken to St. John's Hospital, Long Island City, where it was found necessary to amputate the right leg below the knee and afterward to amputate the left leg at the knee-joint. He refused to take an anesthetic and bore the operation with great fortitude, but he did not rally and died on the following evening. He was born in 18[illegible] and was graduated from Bellevue Hospital Medical College in 1864. He served in the Civil War as surgeon and had been a member of the Newtown Board of Health and was medical inspector of the board of health in the borough of Queens.

Asa W. Griggs, M.D., West Point, Ga., died August 16, at the age of 73 years. He was graduated in 1855 from the medical department of the University of Nashville, Tenn., and began practice in West Point in 1857. He was an honored member of the Georgia State Medical Association, and was at times its orator and president. He was also for several years professor of principles and practice of medicine in Atlanta Medical College; and many years before, filled the chair of surgery in Oglethorpe Medical College, Savannah.

Moses Warren Kidder, M.D., Lincoln, Mass., died at the Waltham Hospital, from appendicitis, August 15, aged 72 years. He attended Harvard and Berkshire medical schools and was graduated from the latter in 1852. He then went into practice with his father in Lowell, where he remained until 1870. During this time he served as city physician and as a member of the school board. On leaving Lowell he went to Lincoln and there resided until his last illness.

Nelson W. Bates, M.D., Central Square, N. Y., died August 11, aged 72 years. He was born in Lewis County, graduated from the University Medical College, New York, in 1864, served as assistant-surgeon in the One Hundred and Tenth New York Volunteer Infantry in the Civil War and was stationed for two years at Fort Jefferson, Dry Tortugas. He had been a resident of Central Square for nearly fifty years.

Adam Lindeman, M.D., Pittsburg, Pa., died at Mercy Hospital in that city, August 20, after an illness of five weeks, from appendicitis and complications following operation for this condition. He was graduated from Jefferson Medical College in 1884, and had practiced for more than fifteen years in Homewood, a suburb of Pittsburg.

H. P. Hugus, M.D., died July 30 at Kealia, Kauai, Hawaiian Islands, at the age of 60 years. He was a graduate of Jefferson Medical College and practiced at Delmont, Pa., and Orrville, Ohio. Later he went to Los Angeles, Cal., and in 1890 removed to Hawaii, where he has since resided.

E. W. Oliver, M.D., died of cancer of the stomach at Mulberry Grove, Ill., August 15, at the age of 57 years. He was graduated from the College of Physicians and Surgeons, Keokuk, Iowa, in 1874, and had practiced since that time in Mulberry Grove and vicinity.

Carl M. Kelley, M.D., Matamoras, Pa., coroner of Pike County, died August 11, from heart disease at the age of 38 years. He was a native of Scranton and was graduated from the College of Physicians and Surgeons, Baltimore, in 1883.

John H. W. Chestnut, M.D., Philadelphia, died from cancer of the stomach at Dutch Harbor, Alaska, August 5. He was graduated in 1871 from the department of medicine in the University of Pennsylvania.

A. S. Lee, M.D., Oakland, Cal., died from appendicitis while en route from Hamburg to New York, and was buried at sea. He was a graduate of the medical department of the State University.

Samuel A. Kennedy, M.D., died at Shelbyville, Ind., August 22, aged 65 years. He was a graduate of the medical department of the University of Cincinnati, in 1857.

F. W. Sawyer, M.D., died at Evansville, Ind., August 13, at the age of 90 years. He had practiced medicine in Evansville since 1851.

E. T. Cody, M.D., a graduate of Rush Medical College in the class of 1889, died August 11, at Jerome, Arizona.

D. W. Gregory, M.D., Benton, Tenn., was shot and instantly killed in a quarrel, August 13.

Societies.

Coming Meetings.

American Academy of Railway Surgeons, St. Paul, Minn., Sept. 5-6.

American Association of Obstetricians and Gynecologists, Louisville, Ky., Sept. 18-20.

Medical Society of the State of Pennsylvania, Wilkesbarre, Sept. 18.

Medical Society of the Missouri Valley, Council Bluffs, Ia., Sept. 20.

American Electro-Therapeutic Association, New York City, Sept. 25-27.

American Public Health Association, Indianapolis, Ind., Oct. 2-5.

Idaho State Medical Society, Boise, Oct. 4-5.

Utah State Medical Society, Salt Lake City, Oct. 4-5.

Wyoming State Medical Society, Cheyenne, Oct. 9-10.

Mississippi Valley Medical Association, Asheville, N. C., Oct. 9-11.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, Tenn., Oct. 9-11.

Vermont State Medical Society, Rutland, Oct. 11-12.

New York State Medical Association, New York City, Oct. 16-18.

Medical Society of Virginia, Charlottesville, Oct. 23.

The American Public Health Association will meet at Indianapolis, October 22 to 26, instead of the first week of the month as originally arranged.

The Saline County (Mo.) Medical Association convened at the county court room August 13. The paper of the day was by Dr. Mills T. Chastain, Marshall, on "Dysentery."

The Baltimore County (Md.) Medical Society held its regular meeting at the Maryland Yacht Club Fishing Shore, Middle River, on August 16. The subject for discussion was "Surgery in Country Practice," which was participated in by Drs. Robert W. Johnston, Thomas H. Emory, B. F. Bussey and others.

The Las Animas County (Col.) Medical Society at a meeting August 6, discussed the subject of public legislation against tubercular infection. A committee was appointed to draft a memorial to the state legislature, urging the enactment of a law regulating the public care and government of tuberculosis in Colorado.

The Winnebago County (Ill.) Medical Society held a meeting at Rockford, August 14, at which Dr. T. H. Culhane read a paper on "Surgical Treatment of Appendicitis;" Dr. Albert Green, on "Cholera Infantum;" Dr. Stoddard L. Anderson, on "Etiology and Diagnosis of Typhoid Fever," and Dr. E. H. Ochsner, Chicago, on "Surgical Treatment of Perforation in Typhoid Fever."

The Grand River (Mich.) Medical Association held its second annual picnic at Spring Lake, August 16. Dr. O. E. Yates, Holland, was chosen toastmaster; Dr. C. P. Brown, Spring Lake, welcomed the association to Spring Lake; Dr. B. B. Godfrey, Holland, responded to the toast "Bald Heads," and the proceedings were concluded with an address by Dr. J. W. Vanderberg, Holland, the retiring president.

The Lake Keuka (N. Y.) Medical and Surgical Association at its annual meeting at Grove Springs, August 14 and 15, elected Dr. Henry Flood, Elmira, president; Dr. W. A. Macy, Willard, vice-president, and Dr. W. W. Smith, Avoca, secretary. About seventy were in attendance. The next meeting will be held the second Tuesday and Wednesday in August, 1901.

The Lehigh Valley (Pa.) Medical Association at its twentieth annual session, August 14, elected the following officers: Dr. Albert A. Seem, Bangor, president; Drs. C. P. Knapp, Wyoming, W. H. Hartzell, Lehigh, A. H. Halberstadt, Pottsville, and O. H. Sproul, Flemington, vice-presidents; Dr. Charles McIntyre, Easton, secretary; Dr. W. P. Walker, South Bethlehem, assistant secretary, and Dr. Abraham Stout, Bethlehem, treasurer.

The Wells County (Ind.) Medical Society held its midsummer meeting at Poneto, August 14. Papers were presented by Dr. Frederic R. Charlton, Indianapolis, on "Management of Non-Surgical Kidney Cases;" Dr. Albert E. Bulson, Fort Wayne, on "Some Eye Lesions Indicative of Constitutional Diseases;" Dr. Alois B. Graham, Indianapolis, on "Intestinal Diseases in Children;" Dr. G. W. McCaskey, Fort Wayne, on "Some of the Problems and Achievements of Preventive Medicine," and Dr. John N. Hurty, Indianapolis, on "Contagious and Infectious Diseases in Indiana."

The British Columbia Medical Association opened its first annual conference at Vancouver, August 9 and 10. The first day was devoted to perfecting the details of organization, drafting of constitution and by-laws, election of officers, appointment of committees, etc. Dr. R. E. McKechnie, Nanaimo, was elected president; Dr. R. E. Walker, New Westminster, vice-president; Dr. J. M. Pierson, Vancouver, secretary; Dr. J. D. Helmeken, Victoria, treasurer. The scientific proceedings opened with a discussion on "Appendicitis," by Dr. John C. Vavie, Victoria; David La Bau, Nelson, and Thomas W. Lambert, Kamloops. Drs. Simon J. Tunstall, Vancouver, A. P. Proctor, Kamloops, Jakes Midway, and J. H. Duncan, Victoria, then read papers on "Preliminary Tuberculosis, its Prevention and Treatment." A discussion on "Injuries to the Parturient Canal" followed, conducted by Drs. O. M. Jones, Victoria; George E. Drew, New Westminster, and Osborne Morris, Vernon.

The Southern Kansas Medical Society will hold its quarterly meeting at Parsons, September 4. The program includes papers by J. T. Davis, Independence, on "Piles;" A. L. Fulton, Kansas City, on "Inflammation;" J. L. Lehew, Pawnee, O. T., on "Gastric Catarrh;" L. S. Wilson, Monmouth, on "Entero-Colitis;" J. W. Porter, Midway, on "Medical Examinations for Fraternal Insurance Companies;" I. E. Stryker, Baxter Springs, on "Hip Joint Disease;" Wm. Frick, Kansas City, on "Significance of Purpuric Eruptions;" C. P. Lee, Pleasanton, on "Neurasthenia;" W. J. Gillett, Parsons, on "Endometritis;" H. H. Bogle, Pittsburg, on "Hydrophobia;" Thomas Barnett, Fort Scott, on "Tertiary Syphilis;" George S. Liggett, Oswego, on "The Microscope."

The Detroit Medical Society.—A new society has been organized in Detroit, which will be known as the Detroit Medical Society. It already has 228 members. It is intended to admit to membership all regular physicians of Detroit and vicinity, those residing outside of Wayne County being regarded as non-resident members with half-dues. Efforts, heretofore unsuccessful, have been made for some time to unite the two leading societies of Detroit. The new society has been organized by the younger men, and it is the hope of the organizers that it will finally take the place of the two other societies and thus remove the trouble that has so long existed.

The first meeting will take place on September 5, at which time Dr. L. S. McMurtry, of Louisville, will read a paper. The officers of the society are: president, Charles T. McClintock; vice-president, H. W. Yates; secretary, L. J. Goux; treasurer, J. E. Davis.

The American Academy of Railway Surgeons will hold its seventh annual meeting at St. Paul, Minn., September 5 and 6. Papers will be read by Dr. Haldor Sneve, St. Paul, Minn., on "How to Treat the Muscular and Joint Sprains of Railway Employees;" C. O. Hunter, Columbus, Ohio, "Remedies;" Dr. W. W. Grant, Denver, Col., "Fractures of the Elbow-Joint;" Dr. D. S. Fairchild, Clinton, Iowa, "Some Additional Observations on Effects of Injury to Peripheral Nerves;" Dr. W. L. Estes, South Bethlehem, Pa., "Hospital Cars on Railways;" Dr. W. U. Cole, Columbus, "Keloid Growths following Traumatisms;" Dr. F. J. Hodges, Ashland, Wis., "Traumatic Separation of the Sacro-Iliac Synchondrosis;" Dr. Wm. H. German, Morgan Park, Ill., Surgical Shock:" Dr. Edward Boeckmann, St. Paul, Minn., "Silver-Catgut Once More;" Dr. J. D. Griffith, Kansas City, Mo., "Effect of Mauser Pistol Bullets;" Dr. C. A. Wheaton, St. Paul, Minn., president's address, "Some of the Needs of the Academy;" Dr. J. T. Eskridge, Denver, Col., "Some Points in the Study of the Medico-Legal Relations of Neurasthenia, and a Short Study of the Plantar Reflexes;" Judge E. A. Jaggard, St. Paul, Minn., "Some Aspects of Medical Testimony:" Dr. James H. Dunn, Minneapolis, Minn., "The Diagnosis and Treatment of Injuries of the Head;" Dr. M. Cavana, Sylvan Beach, N. Y., "Railway Injuries Resulting from Personal Negligence;" Dr. Wm. C. Bane, Denver, Col., "Chip of Iron in Eye—Examination with Fluoroscope, Negative, and with Sideroscope, Positive—Eye Enucleated—Sympathetic Ophthalmitis Sixteen Days Later—Recovery—Exhibition of Sideroscope;" Judge J. T. Durham, Oneida, N. Y., "The Railway Surgeon, a Valuable Aid in the Settlement of Claims for Damages;" Dr. R. H. Cowan, Radford, Va., "Cocain Analgesia;" Dr. J. F. Pritchard, Manitowoc, Wis., "Non-Constriction Dressings in the Treatment of Fractures;" Dr. J. A. Quinn, St. Paul, Minn., "Remarks on Delayed Union and Non-Union of Fractures."

California Academy of Medicine.

San Francisco, Cal., July 24.

Dr. D. W. Montgomery in the chair.

SYPHILIS.

Dr. Tait exhibited a patient, male, 72 years of age, who, seven weeks previously, had contracted syphilis. The chancre on his penis was nearly healed, but considerable induration remained. He had had a typical syphilitic eruption, and a great deal of cephalalgia, all of which had yielded to mercurial treatment.

FRACTURE OF OLECRANON.

Dr. Caglieri presented a successful case of fracture of the olecranon, treated by the closed method, in contrast with the case of fracture of the patella treated by the open method, which he presented at the last meeting. The patient, about six years ago, fell from his bicycle on his right elbow, fracturing his olecranon at its junction with the shaft of the bone. It was treated by a long anterior splint a week, was in plaster a week, then massage was employed until recovery. The result was perfect. The fragments were held together by means of an adhesive strip above the fragments and another in front of the wrist below, both strengthened by adhesive strips around the arm. Through these loops a rubber catheter was passed and tied under slight traction. The question is asked frequently whether all cases of fracture of the olecranon or patella should be treated by the open method or the closed method; his answer is here as in other questions of surgical importance, that the physician should use his own judgment in the particular case. If he has any doubt of the patient having a useful joint, and is sure of his technique, he should use the open method; if not, he should resort to the closed method.

Dr. Henry Barbat said that the results by this, or any method of treating fractures of the olecranon, are not to be compared with those obtained by wiring the fragments. He admitted that this method was superior to other ordinary methods, because in this way one gets an elastic pull, holding together the fragments. Good results were not to be obtained, however, in cases of fracture of the patella by such a method, because in such fractures one has an entirely different kind of joint to deal with, and there is usually considerable blood-clot in the joint.

Dr. E. E. Kelly thought that it was more difficult to get union in fractures of the patella than in those of the olecranon, because, it being a sesamoid bone, and not having the same blood-supply, there was not the same tendency for the fragments to unite. It also takes great pressure to bring fragments of the patella together. In a case he had had some time before, in which a woman had fallen and injured her knee, the doctor who saw her immediately made a diagnosis of broken patella, and had dressed it by means of adhesive straps. He was called in subsequently, and discovered that the quadriceps extensor tendon was ruptured, the patella being uninjured, and that the straps were pulling the bone away from the tendon.

Dr. Dudley Tait thought that the action and importance of the quadriceps extensor tendon had been made altogether too prominent in the treatment of patellar injuries. It does not have as much action as is usually supposed in the separation of the fragments. Not enough importance is given the peripatellar soft tissues, as a causative factor in the separation of the fragments. Separation is very frequently due also to distension of the joint by blood-clot from behind. It is much better to encircle the fragments of the bone with a suture than to wire them.

GALL-STONES.

Dr. J. Henry Barbat presented a case illustrating the difficulty of detecting the presence of gall-stones, even when present in large numbers. The patient, a woman aged 36 years, began suffering twenty months previously with pains in the epigastric region which did not come after every meal, and were not influenced by the kind of food. There was neither nausea, vomiting, nor icterus. The case was diagnosed as gastralgia and all the remedies in the category were given without avail. Finally lavage was resorted to with immediate relief of the pain as soon as the washings came away clear. The patient improved for a few months but she then began to lose flesh as she was unable to keep down sufficient food, it having become necessary to wash out the stomach after every meal. About this time she noticed more severe pain on the right side and considerable tenderness over the right hypochondriac and lumbar regions. Her physicians also discovered a mass in this locality which proved to be a movable kidney; there was no evidence of trouble with the gall-bladder during all this time. When he first saw her he advised nephrorrhaphy. He stitched the kidney with chromicized catgut, and the patient had no severe pains while in bed, but after her return home they returned, and after three months were almost as bad as ever. During one of her paroxysms he found that the point of greatest tenderness was over the gall-bladder, and after an unusually severe attack detected dulness extending from the region of the gall-bladder toward the umbilicus, but could make out no tumor. The dulness gradually subsided and slight icterus appeared. He then diagnosed obstruction of the cystic duct and advised operation. When the abdomen was opened the gall-bladder was normal in size and position and appeared to be filled with bile. Palpation revealed a large calculus at the apex of the viscus, which blocked the cystic duct. The manipulation loosened the stone and allowed the bile to escape, leaving the gall-bladder a little smaller than when normally distended. It was filled with stones and its walls much thickened.

The stones were removed through an incision in the fundus, the edges of the incision stitched to the abdominal wound, and a rubber drainage-tube inserted. Bile flowed freely from the wound for several days and five stones which could not be easily removed at the time of operation passed out through the drainage tube. The gall-bladder was irrigated every day; after ten days, as no more stones appeared, the drainage-tube was removed and the wound allowed to close.

Three weeks from the day of operation the wound was completely closed and the patient able to be around. She has had no recurrence of pain, and has gained considerable weight. The stones removed numbered 284, and while the majority were not much larger than a grain of wheat, several were fully 2 cm. in diameter.

In all cases of gall-stones the possibility of the subsequent formation of more stones must be considered; if in spite of cholagogues and appropriate diet recurrence takes place the proper operation would be a cholecystenterostomy.

The second case is interesting on account of the large size of one of the calculi, and the length of time the patient suffered before the operation. The patient, a nullipara, aged 42 years, had had sharp attacks of pain in the region of the gall-bladder for ten years, but had never noticed jaundice; a diagnosis of possible gall-stones had been made and the patient given salines, olive-oil, and other popular remedies, but her attacks became more frequent, and more exhausting.

He saw her during one of her seizures, determined a slight fullness below the margin of the ninth rib, and a peculiar fremitus, and advised operation.

The incision was made at the right border of the rectus muscle. The gall-bladder was not very large, and required considerable coaxing to bring it into the wound. The fundus was incised and a number of small stones which lay between the wall and a large calculus which filled the lower three-fourths of the gall-bladder were removed. A gush of bile followed the removal of the large stone. A large number of smaller stones passed at the same time; a medium-sized stone was found in the neck, and beyond this more small stones which occluded the duct. Two retention sutures were inserted, and the abdominal cavity closed off by sewing the peritoneum to the gall-bladder. A rubber drainage-tube was introduced for six inches, and a strip of oiled gauze placed between the abdominal wall and the gall-bladder to prevent too great adhesion, thereby allowing that viscus to be returned to the abdominal cavity after it had been sufficiently drained. Only one more stone was discharged, and after eight days the tube was removed and the wound allowed to close.

DR. **KELLY** said that one objection to cholecystenterostomy is the liability to ascending infection from the intestine involving the liver by way of the cystic duct. He had had a case of this kind, in which he had used a Murphy button for anastomosis, but as the button became plugged, he had to make a second operation three weeks later to remove it. At this operation he saw that the gall-bladder had shrunken and was not larger than a duct.

DR. **TAIT** said that the operation done by Dr. Kelly has been practically abandoned by the men who first used it. In all these cases there is infection of the gall-bladder, which demands drainage. He favored stitching the gall-bladder to the abdominal wound, and thus draining it. He believed cholecystectomy unsurgical.

DR. **BARBAT**, in closing the discussion, said that an ideal operation can not always be done. In some cases it was impossible to bring the gall-bladder to the surface and cholecystenterostomy is the operation indicated. The authorities who recommend delay in operations for gall-stones, are not correct. Operation is justifiable where we have strong suspicion of the existence of gall-stones. In performing a cholecystenterostomy he always uses the Murphy button.

ILEO-COLIC INTUSSUSCEPTION.

DR. **CAGLIERI** presented a specimen removed from an infant four months old who died a few hours after the operation. It was impossible to reduce the obstruction, so about three feet of bowel were resected. This child had been ill for four days before the speaker saw it; the condition had been diagnosed as "bowel trouble."

DR. **BARBAT** thought that early operation should be done in all abdominal cases. He attributed his success in the treatment of such cases to be due entirely to early diagnosis and early operation.

DR. **W. I. TERRY** thought that high injections, when used early are of decided value, and probably would have been so in this case. Had the operator made an artificial anus it might have been better than the method he pursued.

Colorado State Medical Society.

Thirteenth Annual Convention, Denver, June 19-21, 1900.

(Concluded from p. 514.)

SYPHILITIC MANIFESTATION IN THE EAR.

DR. **P. F. GILDEN** said that characteristic mucous patches in the middle ear have been noticed, that gummata have been found, and that these yielded to specific treatment in the same way as in other parts of the body. Inflation of the ear does not increase the hearing, neither does it stop other uncomfortable symptoms. He advocates a thorough trial of specific treatment in obscure ear troubles.

SYPHILIS OF THE THROAT.

DR. **T. J. GALLAHER** discussed the subject of syphilis of the fauces, pharynx and larynx. He said that chancre may simultaneously appear on the tongue and tonsil. The earliest symptom is painful deglutition, which persists regardless of treatment. The mucous patch is similar in structure to the initial lesion. He has seen a gumma of the soft palate which occurred 4½ months after the appearance of the chancre.

BONE AND JOINT SYPHILIS.

DR. **W. W. GRANT** said that many cases of hip-joint and Potts' disease in children are caused by hereditary syphilis. In syphilis there is no tendency to pus formation and to necrosis, and operative interference is seldom demanded. Night pains are characteristic of bone syphilis.

INHERITED SYPHILIS.

DR. **SOL G. KAHN** said that hereditary syphilis differs from the acquired disease in being constitutional from the first. There is no primary stage. The child may be born healthy and vigorous, or puny and delicate. The typically syphilitic child is at birth a wasted, wizened, snuffling, feeble creature, with a weak, hoarse cry, the integument being thrown into folds, giving it the appearance of old age. The nostrils, lips and angles of the mouth are scarred by fissure; the submaxillary glands are hard and swollen; the skin is dry or waxy in appearance. Vesicles are most frequently found on the soles, palms or nates. The crescentic notch or Hutchinson's teeth is of great diagnostic value; the incisors are pointed and narrow at their edges, and furrowed with a crescentic notch.

IS SYPHILIS EVER ACTUALLY CURED?

DR. **FRANK FINNEY** said that even if the syphilitic poison loses its power of infection, it may remain latent until by some external cause it is stimulated to new growth. From the present imperfect knowledge of the pathology of this disease, it is evident that we have not yet arrived at a point where we can apply a treatment which is curative.

PROPHYLAXIS OF SYPHILIS.

DR. **E. STUVER** said that legal restrictions and medical examination of prostitutes not only fail to prevent the spread of venereal diseases, but enormously increase the number of clandestine prostitutes. He advocates a single standard of morals for both sexes, and in conclusion reiterated the conclusions of Dr. Ferd. C. Valentine. (THE JOURNAL, xxxiv, 9, 532.)

SYPHILIS AND TRAUMA.

DR. **LEONARD FREEMAN** said that there is little doubt that under favorable circumstances most injuries heal as rapidly and as thoroughly in syphilitic patients as in others. Primary sores respond unfavorably to irritation arising from cauterization or other causes, and a mixed infection may thus be inaugurated resulting in a suppurating bubo.

Secondary syphilis is less closely related to traumatism than either the primary or the tertiary forms. Eruptions of various kinds can be increased in severity by irritation of the skin, such as excessive perspiration, uncleanliness and rubbing of light clothing. The bad effect of tobacco upon the mucous patches within the mouth is familiar to all. There is no doubt that the severity of a syphilitic iritis can be increased by excessive use of the diseased eye. In tertiary syphilis the effects of traumatism are quite noticeable, although they have been grossly exaggerated. Fractures are sometimes directly produced by gummata. He encountered such a condition in the tibia and had to resort to an amputation. Whether rheumatism is regarded as a major or minor factor in specific manifestations, the fact remains that it is slight injuries that are most productive of results. The restorative process following severe lesions are perhaps too active to permit growth of syphilitic germs, this being analogous to what has been demonstrated by experiments in connection with tuberculosis and osteomyelitis.

SYPHILIS IN ARMIES.

Lieutenant-Colonel Henry Lippincott said that in the United States Army we have not had the support of the civil law as have the military and naval authorities in England, but our commanders and surgeons have done their utmost to prevent a large sick list from syphilis. In the United States Army, the methods are chiefly advisory. In the home station the unfortunate soldiers are segregated. The admissions on account of venereal diseases during 1898 were equivalent to 84.59 cases in every 1000 of the strength present; the average duration of cases was 36.46 days. During the calendar year 1898, 71,250 men were examined for the regular army of the United States; of these, 66,237 were white and 5,013 colored; the total number accepted was 54,896. Of every 1000 examined, 9.71 were rejected on account of venereal diseases. The range of variation in the different armies of the world is interesting. In 1000 healthy men, the number of cases of syphilis in one year in the English Army was 105; Austrian, 9; Prussian, 8; Italian, 7.

TREATMENT OF SYPHILIS.

Dr. W. P. Munn said that an indurated chancre that has not been present more than twenty-four hours on a long prepuce is probably the best situated for complete and free removal, circumcision being the preferable operation. Five years ago he removed a sore which had been pronounced to have all the microscopic characteristics of a ture chancre, and the patient remained free from constitutional symptoms. He uses europhen or acetanilid as a dusting powder. The strong 40 per cent. solution of formaldehyde is the liquid application *par excellence* if the surgeon desires to use one. Constitutional treatment should be deferred until secondary manifestations are apparent. This delay is justified because it renders the liability to error in diagnosis less; the regularity of the disease is not interfered with; the patient himself, then more firmly convinced of the nature of his trouble and the necessity for continuous surveillance thereafter; and as a rule constitutional treatment is not curative before the disease itself has become constitutional. The maximum dose of potassium iodid that he employs is 960 grains daily for a period of over a month. The index of a sufficient dose is the beginning of clinical improvement. He has never discovered that the medication used in health resorts differs from that familiar to all physicians, but patients should be sent to a resort when they will not or can not take proper care of themselves.

STATE MEDICINE.

Dr. W. P. Munn, in the address on this subject, said that problems that lie in the borderland of medical science and statecraft constitute the material for the study of state medicine. Among the triumphs of preventive medicine he enumerated the arrest of Asiatic cholera; the decrease of diphtheria and of typhoid fever; the education of the people concerning tuberculosis; the holding in check of the plague; the discovery of its cause, and the preventive measures now employed, and malaria, its cause and means of propagation. Preventive medicine justifies state control of practice of medicine, for every community is at the mercy of the practitioner of medicine when it comes to the recognition of the various contagious disease, and their accurate diagnosis is essential to public health and the concealment of it a crime. He gave a short historical sketch of the model medical license law which was introduced and passed by the legislature of the state of Colorado and which was vetoed by the Governor. He premised the whole discussion by a brief consideration of the underlying principle, and said in part: Among the subjects of legislative control which have long received the sanction of all legislative bodies and the continued recognition of courts of all nations as lawful, a legal requirement qualification of the members of certain trades and professions stands among the first. In no branch of modern acquirements is the need of control by law more obviously recognized, or enforced with such great strictness as in the interpretation of law and the struggle for administration of justice. No man is permitted to pass judicially upon the problems that affect personal rights, property interests or loss of liberty unless he is "learned in the law." And the moment this man "learned in the law" is elevated by the fortune of politics, the favor of the executive or the confidence of the people to the judicial bench, he is invested with a certain assumption of greater integrity, a temporary infallibility, most pleasing to himself and to those who belong to the same profession. But before anyone can hope to attain this infallibility, he must be a member of the bar, that is, he must have passed an examination before a board of members of his own profession who thereupon decide whether his learning is sufficient in amount and his personality of such character as to make him a desirable associate. If they approve of him, he is by the action of the court "admitted to the bar." Still further and greater formalities are necessary before he can practice in the appellate courts or the Supreme Court of the United States. Learning and good reputation are in each instance the requirements of permission. Thus it will be seen that not every one can go to court and take the time of the court in presentation of cases, not every one is permitted to take upon himself the responsibility of defending property rights, of drawing up legal papers, etc. It is universally adopted that such functions are quasi-public ones and must be exercised only by those who have undergone a proper preparatory course of study.

Stationary steam-engineers are required to pass an examination before an examining board. This is done with a view to minimize the danger arising from the explosion of boilers. In order that the health of the family may not be injured through defective plumbing, the state and the city have assumed the power of examining plumbers. The blacksmith who shoes horses is required by law in the State of Colorado to have a certificate of capacity from an examining board. Now, what the medical profession of the State asked was this: "That the integrity and usefulness of our profession be guaranteed to society, and that standards be established for our members for the observance of which sanction should be given." This and more the state long ago gave to the legal and the dental professions, this and more has been given to many of the trades, but to medicine, and to medicine alone, the veto has denied the right or power to establish standards for our membership.

GASTRIC ULCER.

Dr. W. T. Little discussed "The Symptoms, Prognosis and Treatment of Gastric Ulcer." He gave the history of a woman 22 years of age, who had several recurrent attacks of gastralgia and hemorrhage, extending over a period of four years. When she came under his observation, she had almost daily attacks of gastralgia for several weeks, that culminated in a severe hemorrhage, during which she lost from three to four pints of blood. On the second day of the hemorrhage, she complained of severe epigastric pain and tenderness, which rapidly spread up under the ribs into the sides and down over the abdomen. She lay with thighs flexed, and was delirious, but did not vomit. At the end of twenty-four hours she began to improve rapidly.

BULLET IN SPINAL CORD.

Dr. H. T. Pershing read a paper entitled "Localization of a Bullet-Wound of the Spinal Cord: Removal of the Bullet from the Spinal Canal," in which he reported the following case: Mrs. A., aged 42 years, received two bullet-wounds. One bullet was easily extracted; the other entered the back about the level of the eleventh rib and six inches to the left of the median line. Immediately after the shots, she fell, and experienced a numb sensation from the waist downward, and could not move either of the lower limbs. There was severe pain in both buttocks and thighs, and the control of the bladder and the rectum was lost. The muscles above the waist were under normal control. Faradic irritability was entirely lost in the paralyzed muscles, except a perceptible contraction of the right peroneal group. Plantar, Achilles and knee reflexes were absent; but anal and perineal reflexes lively. The lesion was diagnosed to be located mainly opposite the twelfth dorsal vertebra, extending both upward and downward, but not so far as the upper border of the eleventh dorsal or the lower border of the lumbar vertebra. Skiagraph of the lower spine gave a faint indication of a foreign body between the twelfth dorsal and first lumbar vertebra. Dr. Craig removed the spine and lamina of the twelfth dorsal vertebra, but nothing abnormal was found. The spine and lamina of the eleventh vertebra were then removed, and a foreign body was found in the spinal canal, a little to the right of the median line. This was easily removed; the wound was dressed, and the patient was relieved to a great extent, but there was no restoration of function. The pains returned with former severity, and death, due to exhaustion, occurred thirty-five days after the injury was received. No autopsy was allowed.

FRACTURES OF THE PATELLA.

DR. F. H. MCNAUGHT reported five cases of fracture of patella, in which operative treatment was used. In summarizing, he said that the indications for arthrotomy are: When the fractured parts can not be returned to their normal condition by manipulation; when the fracture is of such a nature that serious primary defect is to be expected; when any suspicion of infection follows the fracture; if the patient is in the best possible condition; if the surroundings are favorable—an aseptic operating-room; if the remote possibility of infection is explained to the patient before the operation.

IMMUNIZATION FOR TYPHOID FEVER.

DR. H. W. MCLAUTHLIN reviewed the literature on this subject, beginning with the experiments of Brieger, Kitasato and Wassermann in 1872, and the work of Dr. A. E. Wright of the English Army, in 1897. He said that the consensus of opinion seems to be that the inoculations with Wright's serum are harmless, and that some degree of immunization against typhoid fever is conferred by them. He expressed a hope that the reports of the inoculations in South Africa would show another stride forward in the praiseworthy efforts to control this great scourge.

HEALTH BOARDS AND DIPHTHERIA.

DR. G. E. TYLER read a paper entitled "The Relation of State and Local Boards of Health to Outbreaks of Diphtheria," in which he described the methods to be used by health officers in their battle with this disease. He said that bacteriologic facilities should be offered free of charge to every citizen. In small communities it is quite out of the question to maintain a bacteriologic laboratory, and it then becomes the duty of the State Board of Health to supplement the work of the local board by furnishing the necessary facilities. The State Board of Health must have a competent bacteriologist, not appointed for political reasons. The culture outfits should be as compact as possible in order that the cost of sending them may be reduced to the minimum. Through the efforts of the Colorado State Board of Health the regulations of the post-office were so modified that a smaller outfit can now be sent and a gain of twelve hours in time was made in the receipt of specimens. In every positive case immediate report will be made by telegraph, and the State Board of Health of Colorado will have depots established in every county on or before Sept. 1, 1900.

The antitoxin should be provided for all infected individuals who can not afford to buy it. The record made by the health authorities should show the exact location of the patient, the number and the names of the rest of the family, and all others known to have been exposed. The milk, water and ice supply should be noted, and the school or Sunday-school visited by the children. The house should be placarded, and quarantine should be maintained until the bacteriologist reports the throat free from diphtheria bacilli. In fatal cases, the funeral should be private and under the supervision of a health officer. The exposed should be given immunizing doses of antitoxin. The state or local board of health should have circulars for public distribution, and one of these should be placed in the hands of the head of the family where the disease appears. Toys with which the child played should be burned, and the room fumigated with sulphur, five pounds to each 1000 cubic feet of space.

DISEASES OF THE BRONCHIAL GLANDS.

DR. J. N. HALL discussed this subject in his presidential address. He said that American medical literature is singularly barren on the subject of the diseases of the bronchial glands. The glands are enlarged in conjunction with involvement of the lymph-glands of the entire body in leukemia, pseudoleukemia, leprosy, syphilis, and general tuberculosis. Primary lymphosarcoma and lymphadenoma also occur, as well as cancer and fibroma. The largest glands are found in connection with disease of bone. Simple lymphadenitis arises from any acute or chronic process—bronchitis, pneumonia, bronchopneumonia, pleurisy, and subacute or chronic changes following measles and whooping-cough, typhoid fever and diphtheria. "Black glands," in Miner's phthisis are frequently seen. In tuberculosis, the bronchial glands become enlarged and granular, undergo cheesy degeneration and are deeply pigmented. In a case at the Arapahoe Hospital, a single gland near the bifurcation of the trachea was an inch in diameter and entirely caseous. Bacilli of tuberculosis are found in bronchial glands, especially in children. In cancer of the lungs or of the esophagus, the bronchial glands are not enlarged, and in gangrene of the lungs, they become gangrenous. The enlargement of the bronchial glands leads to pressure upon contiguous organs, and evidence of such pressure will be found interfering with respiration from compression of trachea or bronchi; hoarseness or aphonia from pressure upon the recurrent laryngeal nerves; dilated pupil from irritation of the sympathetic; contracted pupil from its paralysis; dysphagia from compression of esophagus; tachycardia from abolition of vagus influence; diaphragmatic neuralgia from pressure upon phrenic nerve; edema of the lungs from compression of pulmonary veins. The treatment of diseased bronchial glands in tuberculosis, bronchopneumonia, those following measles and whooping-cough should consist of cod-liver oil, iodid of iron and general tonics. Counterirritation is recommended. If the glands suppurate and pus is near the surface it should be evacuated. Sudden dyspnea, not otherwise accounted for, especially in a child, who from previous disease involving the respiratory tract, may be suspected of having broken-down bronchial glands, would call for the same vigorous measures as if a foreign body had been inhaled.

VALUE OF INSUFFLATION OF ESOPHAGUS, STOMACH AND COLON.

DR C. D. SPIVAK presented a paper entitled "The Diagnosis and Therapeutic Value of Insufflation of the Esophagus, Stomach and Colon," in which he said that the diagnostic value derived from insufflation of the stomach is, 1, determining the capacity of the stomach by the insufflation of a measured quantity of air; 2, the size of the stomach by percussion over distended area; 3, the location of the stomach by inspection, palpation and percussion, the downward and vertical displacement of the viscus can therefore be diagnosed; 4, the patency of the gastric orifices by the rapidity with which the stomach fills up; 5, the shape of the stomach, which may show an intermediate constriction—an hour-glass stomach; 6, displacement, appearance or disappearance of tumors; 7, adhesions.

The diagnostic value of insufflation of the colon is that it aids in determining: 1, location; 2, stenosis; 3, dilatation; 4, tumors; 5, gastro-colic fistula, which may be recognized by the fact that when the colon is inflated the air will eventually distend also the stomach; 6, perforation of the bowel, as suggested by Sutton. (THE JOURNAL, xxxiii, 27.)

Insufflation of the esophagus will indicate the degree of obstruction, and will differentiate between stricture and spasm of the esophagus. It will fill up a diverticulum in the upper third of the esophagus and make it visible. Insufflation will also differentiate between diverticulum and dilatation; for in the latter the air will pass into the stomach, and in the former, the lumen of the esophagus will be obstructed.

The therapeutic value of insufflation of the cc [illegible] been recognized in invagination and volvulus. He [illegible] u [illegible] of insufflation in chronic constipation, and [illegible] foreign body in the esophagus can be pushed [illegible] danger by insufflation than with a bougie, [illegible] be tried in esophagismus.

Therapeutics.

Cancer of the Stomach.

℞.	*Bismuthi subnitratis*	ʒiv	16	
	Acidi carbolici	m. xvi	1	
	Aquæ chloroformi, q. s. ad	℥iii	96	

M. Sig. One tablespoonful before eating. —*Thornton.*

Palatable Creosote Mixture.

℞.	Creosoti	ʒi	4	
	Tinct. gentianæ	ʒii	8	
	Spts. vini rect	℥ii	64	
	Vini xerici, q. s. ad	℥viii	256	

M. Sig. One dessertspoonful four or five times a day. —*Medical Record.*

A Substitute for Alcohol.

In cases of chronic alcoholism, the following will be found a satisfactory substitute for the beverage:

℞.	Tinct. nucis vomicæ	℥ss	16	
	Tinct. cinchonæ comp	ʒiv	16	
	Tinct. *capsici*	℥i	32	
	Tinct. gentianæ comp., q. s. ad	℥vi	192	

M. Sig. One dessertspoonful four times a day well diluted. —*Gould.*

Spray in Acute Colds.

℞.	Acidi carbolici	m. viiss		5
	Ichthyolici	ʒi	4	
	Spts. vini	ʒiiss	10	
	Aquæ destil., q. s. ad	℥iii	96	

M. Sig. As a nasal spray two or three times a day. —*Exchange.*

Stomach Lavage.

℞.	Sodii biboratis	℥ii	64	
	Acidi salicylici	℥ss	16	
	Acidi borici, q. s. ad	℥iv	128	

M. Sig. Two teaspoonfuls to be added to a quart of warm water for washing out the stomach by means of the siphon tube.

For Gravel.

℞.	Sodii bicarbonatis	ʒiss	6	
	Acidi benzoici	ʒss	2	
	Sodii phosphati	ʒiiss	10	
	Aquæ (boiling)	ʒvi	24	

M. Dissolve, filter, and add distilled water ℥vi. Sig. Two tablespoonfuls three times a day in uric-acid gravel. —*Jour. de Med.*

Anaphrodisiac in Gonorrhea.

℞.	Ext. ergotæ fluidi	m. xv	1	
	Tinct. gelsemii	m. v		33
	Potassii bromidi	gr. xx	1	33
	Tinct. hyoscyami	m. xxx	2	
	Syrupi aurantii, q. s. ad	℥ss	16	

M. Sig. Shake. One dose at bedtime. —*Lydston.*

Menorrhagia.

The following is recommended, in *Le Progrès Médical*, for treatment of menorrhagia:

℞.	Salipyrin			
	Potassii bromidi, āā	ʒiiss	10	
	Ext. viburni prunifolii fluidi	ʒv	20	
	Aquæ destil	ʒvi	24	
	Syrupi aurantii	℥iss	48	

M. Sig. A teaspoonful to be taken in the evening the fifth day before the expected period, the same quantity morning and evening on the fourth and third days, three teaspoonfuls on the second day, and four teaspoonfuls on the day before and on the day of the appearance of the menses. —*Med. Bull.*

Sweating of Feet.

℞.	Pulv. aluminis (burnt)	ʒv	20	
	Acidi salicylici	ʒiii	12	
	Amyli, q. s. ad	℥ii	64	

M. *Sig. To be dusted in the shoes.*

Or, when the perspiration is essentially offensive:

℞.	Acidi borici	ʒv	20	
	Tinct. benzoini	℥ss	16	
	Alcoholis	Oi	512	

M. Sig. Apply locally. —*Encyclopedia of Med.*

Rickets (Rachitis).

Kassowitz was the first to advocate the employment of phosphorus. He claimed that the disturbance in rickets was due to a chronic inflammatory process in the osseous tissue, and that phosphorus lessened the hyperemia by restricting the growth of the vessels.

℞.	Phosphori	gr. 1/6		01
	Solve in olei olivarum	ʒiiss	10	
	Pulv. gummi arabici	gr. lxxv	5	
	Syrupi simplicis	m. lxxv	5	
	Aquæ destil	℥iiss	80	

M. Sig. Shake. One teaspoonful daily.

James Stewart: Am. Text-book of Ther.

Or,

Medicolegal.

An Irrelevant Opinion.—The rule in regard to the admissibility of a proffered expert, the Supreme Court of Missouri, in the case of Graney vs. the St. Louis, Iron Mountain & Southern Railway Company, is that the competency of the witness as an expert must be first affirmatively established. He must have special skill in the subject concerning which his opinion is sought to be given. But the opinion of the witness as to his own qualifications, the court declares, is irrelevant, and carries no weight with it. Besides which, the court holds that opinions grounded on mere conjectures or speculation are inadmissible in evidence.

Disorder or Disease.—In his answer, made to a medical examiner, an applicant for life insurance stated that he had not, since childhood, had the disease or disorder of "spitting or raising of blood." But the uncontradicted evidence showed that he had spit blood about a year before the policy was issued. However, it was insisted that, though the insured had spit blood, the spitting was not a "disease or disorder of spitting or raising of blood," as contemplated in the question submitted to him, because he had spit but once, and that, therefore, it was error to hold that an untruthful answer had been made. Not so, however, thinks the Supreme Court of Pennsylvania. It says, Smith vs. Northwestern Mutual Life Insurance Company, that the answer was not true, although a false answer may have been unintentionally made. The applicant may have really believed that he had not had disease or disorder, but he did have spitting of blood; and although it may not have been at the time a disease, with him, as popularly understood, it was at least a disorder, which has been defined to be want of order, irregularity, or derangement of the animal economy. If there had been order in his system, and no irregularity, there would have been no spitting of blood. It was disorder, if not disease, and, having had either, the answer, which he warranted, and may have believed, to be true, was false; and that falsity, the court holds, invalidated the insurance.

Dying Declarations Taken by a Coroner.—Independently of any statutory authority, the Supreme Court of Rhode Island holds, in the case of State vs. Jeswell, that a dying declaration, in which the circumstances of [illegible] rec[illegible] are the subject thereof, taken by a magis[illegible] missible against the accused, if it is clea[illegible] that the declarant fully believed that his [illegible] at the time of making the declaration. Oral and unsworn declarations of the injured person are also admissible in evidence, if it appears that they were made in view of impending death. Such declarations, the court goes on to say, are admissible as evidence against the accused, not because they constitute an exception to the constitutional right of the defendant to be confronted with the witnesses against him, but because they were admissible at common law, and there is nothing in the constitutional declaration to shut them out. However, the court thinks it pertinent to remark in this connection that, owing to the necessary infirmities of dying declarations, and particularly to the fact that they are made in the absence of the accused, and hence without any opportunity to cross-examine or contradict the makers thereof, the law does not look with favor thereon, and they should be received with great caution, and every reasonable opportunity should be given the defendant to ascertain the facts connected with the transaction. So, while the court could not say, as matter of law, that the declaration in question in this case was not admissible without it, it declares that it would have been better satisfied if the trial court had required the coroner to testify as to the condition of the deceased, how he appeared, what he said, and what was said to him by the coroner, regarding the statement and regarding his condition, and also as to whether the statement was read to the deceased before signing it.

Accounted Physician and Patient.—A physician had been called in consultation by the permission of the attending physician, and had seen the patient four or five times. He was informed of the treatment and of the prescriptions. He gave his opinion on the treatment in the past, and not only advised, but ordered, the treatment of the future. He advised a surgical operation. Under these circumstances the second appellate division of the Supreme Court of New York holds, McCready vs. Staten Island Railroad Company, that the relation of patient and physician existed, so as to render admissible in evidence testimony of the latter relating to the statements made to him by the former as to his then present condition, pain and suffering, as statements made to his physician with a view of treatment. It says that he did not take the patient out of the hands of the attending physician, but such, it adds, is not the function of the consulting physician, as implied in the very term. Furthermore, conceding that the physician was an expert, in that he stated that he expected compensation at a fixed rate per diem, the court holds that this would not change the case, for the question was as to the relation that existed between the witness and the patient at the time the testimony in question was elicited by the witness. It may also be noted, in passing, that there was testimony in this case which, if credited, warranted the finding that the railroad accident involved in the case caused a hernia, and the court says that merely because the finding of the jury to that effect accorded with the views of one set of physicians, and not with those of the other set, it could not test the verdict by weighing the medical testimony or by arraying the physicians; for the jury determined the fact upon the evidence, which included these opinions only to the extent that it believed and valued them.

Liability for Wrongful Location of Pest-House.—City of Henderson vs. Clayton is the title, on its second appearance before the Court of Appeals of Kentucky, of an action brought by the latter-named party to recover damages for the location of a city pest-house within one mile of its corporate limits, by reason of which she and her family took the smallpox. She first sought to recover against the city and the municipal officers jointly. But the court held, on the first appeal, that she could not sue the city and its officers jointly, and on return of the case to the circuit court she elected to prosecute the action against the city alone. After this, a trial was had, resulting in a verdict and judgment against the city for $2,775. From this judgment the city prosecuted the appeal, the decision of which is the present subject of consideration. Now, section 3909 of the Kentucky Statutes provides: "It shall not be lawful to locate or maintain any pest-house or other place intended for the treatment of eruptive diseases, or diseases which are contagious or infectious, within the corporate limits of any incorporated city or town, or within a distance of one mile of the boundary line thereof. Any officer of any city or town, or other person, who shall violate the provisions of this act, or in any wise aid or abet therein, shall be deemed guilty of a misdemeanor, and upon conviction thereof in any court of competent jurisdiction, shall be fined not less than five hundred dollars nor more than one thousand dollars, and be liable in damages to any person injured thereby, and if willfully done, such person or his heirs or representatives may recover punitive damages." It will be observed that, while the statute imposes a duty upon the city, it provides a remedy by action only against the city officers in behalf of the person injured. But the court holds that, as the city was authorized by law to establish and maintain a pest-house, the acts of its officers in establishing and maintaining the pest-house in question were its acts, and it was responsible to the party aggrieved, as well as its agents through whose instrumentality it acted. Moreover, the court says that while it said on the former appeal that a common-law cause of action was stated against the city, it was not meant that the petition stated only a common-law cause of action independent of the statute. It holds the averments sufficient to constitute a cause of action independent of the statute, and also a cause of action, which, according to the common law, arises from the violation of a statute enacted for the protection of the citizens, for, from time immemorial, where a statutory duty for the protection of individuals had been violated, it says, an action at common law might be maintained. So, while the above statute is silent as to a remedy against the municipality, nothing being provided as to the remedy against it for its doing what the statute makes unlawful, the court holds that the common-law rule applies; for the wrong is the act of the city whose orders the municipal officers execute, and as the remedy against the officers might, in many cases, from insolvency and the like, be wholly inadequate, this provision of the statute, nothing to the contrary appearing, the court holds, must be regarded as merely cumulative. Wherefore, the court holds that the City of Henderson was liable for such damages as the party suing sustained by reason of the city's violation of this statute, although the latter does not in terms impose this liability on it. And while the verdict was large, the court holds that it was not so large as to justify it in setting it aside, considering the loathsomeness of the disease, and the anxiety and suffering it must have entailed upon the party suing.

AMERICAN.

1. **Extrabuccal Feeding.**—Ewald describes the methods and indications of feeding by other methods than the mouth, the power of the large intestine to take up the nutritive elements; also the effects of subcutaneous injections of nutritive substances, and the methods he uses in both these plans of extrabuccal feeding. He thinks the following combination is the one to be most recommended for dietetic enemas: Two tablespoonfuls (40 grams) of wheat flour are stirred into 150 c.c. of lukewarm water or milk and to this mass one or two eggs and a pinch of salt (3 gm.) are added, and the whole is beaten up with 50 to 100 c.c. of 15 to 20 per cent. glucose solution. The addition of a small amount of alcohol in the form of a glass of claret acts as an analeptic. Such an enema corresponds to 450 calories, of which, to be sure, only a portion fulfill their physiologic destiny. Such a combination may be modified by varying its constituents and adding some peptone preparations, but the more complicated the composition the more difficult is it to recommend and the more probable the production of irritation. He finally mentions the nutritive enema in concentrated form consisting of suppositories of peptonized meat or milk and shows by experiments reported that a fat-free dog can be made to accumulate dog-fat by subcutaneous injections of butter and that it may undergo complete metabolic consumption. Observations on man have shown that the same general principle applies, but the feeding by this method is not to be compared with the nutrient enemata for introducing fat into the system. His conclusions are given as follows: 1. Extrabuccal feeding does not completely replace feeding by mouth, and is not permanently capable of answering the demands of metabolism. In most cases in which this method exclusively is resorted to a state of malnutrition sets in from the outset. An exception to this rule occurs in those cases of gastric fistula in which the operation was necessitated by a benign stricture of the esophagus. 2. For a short time, in weakened individuals whose metabolism is below normal, it may be possible through extrabuccal feeding to increase the nitrogen conversion and even to cause an accumulation of nitrogenous substance and fat. 3. The best results are obtained when it is a question of a temporary replacement of the natural feeding per os, or when extrabuccal feeding is resorted to as an accessory measure to the former. 4. Nutritive enemata are to be preferred to the subcutaneous injection of oil. The applicability of the latter lies rather in isolated cases than as a measure adapted to widespread use in practice.

2. **Migrated Abdominal Tumors.**—Edebohls reports four further cases in addition to the hitherto reported twenty-five or thirty operated on for migrated ovarian or parovarian tumors and tabulates the cases that have been reported.

3. **Posterior Colpoceliotomy.**—The vaginal route for operation in cases of lesion of the adnexa and uterus is advocated by Cumston, who maintains that the abdominal incision should be avoided when possible, and that for all such operations the vaginal should be the preferred route. He reviews the statistics reported by different surgeons and the objections that have been raised. The slowness of the operation is a valid objection in only a small proportion of the cases, and to the objections that the clamps are a serious encumbrance, he says that they should not be employed until the pedicle has formed and the ovaries and tubes are ready to be removed. In all cases that are suitable to this operation, the field is as readily accessible to sight as through the abdominal incision and it has the advantage over the abdominal operation of affording drainage which is advisable since, with that most efficient toilet, some infecting fluid may be left behind. He does not agree that conservative surgery can not be performed by this method or that there is not sufficient space to work. The vagina can be rendered quite as sterile as the abdominal wall, and inasmuch as every operation should be considered in the beginning as experimental, the objection that it is difficult to stop if the condition of affairs is not found to be suited to the method followed fails. He has never seen a case of post-operative enterocele from this method nor heard of a case of intestinal occlusion. If fistulas occur they are in a much better situation than in the abdominal wall. Anterior colpoceliotomy and the lateral colpoceliotomy of Stratz may also be of use in certain cases. He describes the different conditions which he thinks are adapted to this particular operation, such as vaginal fixation, diagnosis of tumors, etc., removal of adnexa, diseases of the tubes, encysted salpingitis, retrouterine hematocele, etc. Extensive adhesions are contraindications to the removal of pathological conditions treated by either this or the abdominal route. A very high position of the adnexa in the pelvis and especially the impossibility of bringing them down low enough to be within reach are positive contraindications for this operation. The same is true of the high position of the uterus. In this method the patient is placed in the lithotomy position, with thighs well flexed, and he also uses the exaggerated Trendelenburg position. The choice of use of ligatures or clamps depends entirely on the preference of the operator; he prefers the latter. He has never seen any advantage in closing the vaginal incision with sutures after the removal of nonsuppurating lesions and rather prefers to insert a wick of gauze which can be removed in three or four days, and within a week or ten days the incision will have been found to be completely closed.

5. **Military Surgery.**—In this installment Borden describes the effects of the small-caliber bullet on the epiphyses of bone and on spongy bone generally. The effects are quite different from those on the harder bony tissues. They are generally clean perforations or groovings, unless the bullet has been distorted by the ricochet, but when the bullet has become deformed its effects will be much more serious. Shrapnel wounds are like those of the old-fashioned bullet of low velocity. The same is true of the old-fashioned revolver wounds. The modern small-caliber pistol will produce effects similar to the small arms of the infantry. Lodged bullets were noticed to be frequent in the Spanish-American, while they are rare in the South African war. The author accounts for this by the condition of the ground on which the fighting was done. In Cuba the battles were fought in the forests and the bullets were interrupted by trees. In South Africa the fighting apparently has been done in the open. As regards the question of removal of lodged bullets, he thinks they should be removed when they are producing dangerous symptoms, when it is possible and when it will not endanger life or invoke more serious trouble than the bullet itself is producing. It should never be removed in the field or field hospital unless aseptic technique is available or the danger that arises from its presence is greater than that from the infection that may arise. Probing for bullets should be entirely abandoned excepting in cases of absolute necessity. The methods of using the X-ray in military practice are discussed and the conclusion reached that it should not be used on the field or in the field hospital as it is not necessary there. The shell wounds are much more serious than those from the small-arms, because of the size and irregularity of their fragments and greater chances of infection. The risks of conservatism in the treatment of such wounds are very great and the judgment of the surgeon will often be severely tested. Wounds from side-arms, etc., present no peculiarities in modern practice. As regards regional injuries, flesh wounds of the head may be considered of minor importance. Wounds of the skull produce a large proportion of the mortality and Dent advises that in every case where the skull is grazed, trephining be practiced for the reason that injury of the brain is almost sure to have occurred. In a certain number of cases, however, the small-caliber bullet penetrates and perforates the skull and the brain with little traumatic disturbance and astonishingly little damage to the individual. This has been one of the greatest surprises since their introduction. The mortality from skull or brain injuries made by the small-caliber bullets in the late Spanish-American war is high. The statistics from the Boer war are not yet available, but it is probable that they will be similar in their results.

11.—Ibid., August 25, p. 510.

12. **Congenital Shoulder Dislocation.**—Porter reports the case of a child four months old, in which a thorough study convinced him that it was a congenital, not a traumatic, case of sub-spinal shoulder dislocation. It was reduced under anesthesia, though there was a tendency to relapse; the head of the bone would not stay in place. He says from his review of the case and the literature that he thinks it is of fundamental importance to determine between traumatic and developmental cases of this lesion, and the pathology of the congenital cases is not sufficiently known to indicate the most promising line of treatment, and that none of the operations that have been done have established a successful method or added much to the knowledge. When the history and measurements prove the case to be developmental and remembering the probable deficiency of development of one or both articular surfaces, early operation before the humeral head has formed itself a new facet under the spine and become itself deformed, offers the best results.

13. **Action of Gelsemium Upon the Motor Nerves.**—The effects of gelsemium on the cells of the motor nuclei of the nerves have been experimentally studied by Whitehead, who concludes as follows: 1. Toxic doses of gelsemium produce chromatolysis of the cells which constitute the nuclei of the motor cerebral nerves. 2. The alterations produced are not specific, but are quite similar to those caused by various other agencies which act injuriously upon motor nerve cells.

14. **The Morphin Habit.**—McBride believes that the sudden withdrawal method of the morphin habit cure is not now practiced, and whether the rapid or slow method of reduction is employed depends on the power of the patient to endure. It is necessary that the patient be completely under control, restricted in his communications and especially from direct intercourse with the rest of the world; otherwise in spite of his desire to be cured, there is a possibility of his obtaining the drug surreptitiously. During rapid reduction he keeps the patient in bed or at least lying down; the amount of each reduction and the length of time intervening varies with the cases. It is possible to shut off large quantities of morphin at once because the system makes very little use of more than a certain amount. The patient should be allowed to recover from the effect of each reduction before the next one is undertaken, especially when the reduction in proportion to the amount last taken, causes suffering; it may sometimes be well to return to the former dose temporarily. The habits of the patient as to taking the drug should be considered, as it makes the matter easier for both him and the physician. To quiet the discomforts during the period of reduction he believes in the use of hot baths, massage once a day and for medicine the bromids are the best, but bromism should never be produced. For tonics and stimulants he prefers quinin, nux vomica, or strychnin, giving the latter in a pill and in small doses. The extract of coca is also helpful. For sleeplessness sometimes all the hypnotics fail, but various ones should be tried. Chloralamid sometimes acts admirably, and sometimes chloral and hyoscyamus produce sleep when nothing else will. When time is not important, a still slower method of reduction is more comfortable for the patient. The quitting of the habit, however, is only a part of the cure; the patient should be placed under environments completely normal which will help him to get it out of his thought, etc., and build up the shattered nervous system. The craving for morphin is often strong for a long time after the drug has been discontinued and the patient should be under control for months or a year before he is allowed to return to his occupation.

15. **Enterocolitis.**—Tannopine is recommended by Fitch as an efficient drug in intestinal disorders. It can be administered with benefit both by the mouth and the rectum and is easily absorbed, is efficient in all forms of enteritis, colitis, and inflammatory intestinal disorders and should be continued in small doses a few days after the bowels appear to be normal. It is completely innocuous and can be given without risk to the smallest infants in doses from 3 to 8 gr. four times daily, and in older children and adults from 7 to 15 gr. It acts by the tannic acid of the compound combining with the albuminous substances, forming albuminates, which causes contraction of the surrounding connective tissues and diminishes reflex activity and sensibility of the muscular tissue. Urotropin the second constituent of this division which takes place in the alkaline and intestinal contents acts as a disinfectant, restoring the integrity of the mucosa and stopping short the process of inflammation.

16. **Suprarenal Extract.**—The use of suprarenal extract in diseases of the nose, pharynx and larynx is discussed by Oppenheimer, who finds that it has two distinct actions: Absolute blanching of the parts followed by almost imperceptible constriction, which increases, however, in some regions, in the nose especially, until the tissues can be contracted down to the osseous structures. It acts only on the mucous surfaces, normal or otherwise, no change being produced in the serous surfaces or unbroken skin. It produces its effects by contracting the arterioles and cavernous sinuses by direct action upon their muscular walls, and its physiologic activity is limited to the area of the membrane brought into direct contact with the drug, differing in this respect from cocain. Its use is mentioned in epistaxis, hay-fever, after operations and in controlling post-operative bleeding. Its action continues in the majority of cases from four to five hours—sometimes even longer. It has no action on the blood itself and does not cause irritation. It is a sedative astringent to mucous membranes in its effects. No vicious habit is liable to be produced, and no special tolerance for the drug is developed; it can be used repeatedly in the same person with the same effects.

18.—See abstract in THE JOURNAL of July 7, p. 52.

19. **Surgical Pain.**—Ryder reviews the whole subject of surgical, and especially abdominal, pain, its signs as shown in gesture and attitude, and the referred pains of various kinds. He advances the idea that the solar ganglion is practically an abdominal brain. In his classification of pain he follows Lomer, of Hamburg, recognizing traumatic pain, contractile pain as shown in visceral lesions, inflammatory pain, and hysterical pain of the abdomen. The significance of abdominal pain is hard to determine in every case. Its location is one of the valuable points settled when elicited by pressure. Rigidity of the muscular wall is the next important aid. The causes of pain from obstruction, strangulation, volvulus, stricture, fecal accumulation, tumors, peritonitis, appendicitis, pelvic disorder, etc., are all noticed in detail with their significance and importance.

20. **The Psychic Factor in Disease.**—Greenleaf illustrates certain propositions which are given as follows: 1. That some cases of illness are simply neuroses without appreciable pathologic lesions. 2. That causes capable of producing such neuroses may act while disease is present and should be guarded against. 3. Purely psychic causes, as shock, grief, and the like, may pave the way for, if not directly cause, profound pathologic disturbance. 4. Attention to the psychic is capable under some conditions of so turning the scale to health that it may arrest, even perhaps cure, otherwise fatal pathologic conditions. 5. Attention to the psychic should be considered a routine measure in the treatment of delirium from toxic causes, as alcohol, belladonna, ether, and the like. 6. Attention to the psychic should also be considered a routine measure in the treatment and in the prevention of delirium in febrile states, as of typhoid. 7. Nurses should be able to enter into psychic relations with their patients; otherwise the value of their services is much lessened and may be harmful. He thinks the value of psychic treatment is not sufficiently appreciated and considers it especially important to nurses. Nurses graduated from the smaller hospitals are better in this respect than those who have had their training in the larger institutions as they are less slaves to routine and have had more special and individual care of patients. Another point which he makes is that the importance of the psychic element in the treatment is emphasized by the modern crazes of "christian science," mental healing, and homeopathy.

24. **Alcoholism.**—This article is the same as that published in The Journal of August 11, with the exception of the cases.

25. **Antitubercle Serum.**—Stubbert reports the subsequent histories of nine cases that have been treated with antitubercle serum in connection with climatic and hygienic measures. He refers to a former paper in regard to this subject, in which 39 per cent. were reported as apparently cured. Those whose histories have been traced are divided into two classes, representing those who have been discharged three and two years respectively. Four have been away three years and in all there seems to be an arrested or very much improved condition if not an absolute cure. In one there remains a slight dulness at the right apex as at the time of discharge. The five that have been away two years are all in excellent condition, and he reports in addition an apparent cure in an advanced case. In addition to these, nine cases are reported of those who have been away for one year at least and have spent at least one winter in their old environment and three other apparently arrested cases. As a résumé, he says that of those discharged apparently cured three years ago, 11 per cent. have remained cured; two years ago, 14 per cent. have remained cured; and 69 per cent. of those who have spent at least one winter in their old environment. He concludes that instead of the hoped-for specific we have in antitubercle serum simply another auxiliary to climate, hygiene and dietetic treatment. The results of two years' study of the subject would seem to indicate: 1. Further confirmation of the conclusions of the preliminary paper in 1898; the use of serum does not tax the functions of digestion or produce gastritis, diarrhea, or loss of appetite; in cases in which bacilli have disappeared, they have been lost while the sputa were still present, whereas in creosote cases the last specimens of sputa still contain bacilli. 2. Immunity seems to be established in apparently cured cases, capable of protecting the patient effectually in his old environment at least two years, and perhaps for a longer period. 3. The fact that cases for treatment must be selected, even among those in the incipient stage, and that it is less effective in low altitudes and city environment, conclusively ranks antitubercle serum among the auxiliaries to climatic treatment of phthisis, rather than as a specific.

26. **Infantile Paralysis.**—Bondurant reviews the history of acute anterior poliomyelitis as it occurs in children, and the difficulties of its diagnosis, and maintains that it is possible by treatment to prevent the contractures, deformities and extreme incapacity so common in the ordinary cases. He thinks after the fever has subsided that massage, tonics, and electricity can all be used, and surgical procedures in some cases. No case of infantile spinal paralysis, however unfavorable, should be regarded as beyond the reach of treatment.

27.—See also ¶ 11, above.

28.—Ibid., ¶ 9.

29.—Ibid., ¶ 7.

30.—Ibid., ¶ 6.

32. **Fissure of the Rectum.**—Patients suffering from rectal fissure usually let it go until it becomes chronic and makes more trouble than would otherwise have been the case. Monroe has never known a case to get well without treatment of some kind. Probably the first thing to do in its treatment is to relieve the constipation, regulate the diet, prohibit the use of alcohol and highly seasoned food, pies and cakes. Tea and coffee are objectionable; the use of laxatives such as compound licorice powder at night two or three times a week, and enemas is advised. The patient should drink plenty of water. He gives frequent enemas and recommends the use of at least two or three quarts of water at a time. For local complications he suggests, after cleansing, peroxid of hydrogen, and later applications of nitrate of silver, 10 gr. to the ounce of water. Five or six applications ought to cure. Next to this he prefers carbolic acid, with one to three parts of olive oil. He has had good results from ichthyol. Before using some of these preparations, it is well to apply a 4 per cent. solution of cocain muriate. In irritable ulcer of long standing, no local applications are used and the preferred of all operations is divulsion with slight cutting through the fissure. The patient should be given chloroform, placed on the left side on the operating-table, and the index fingers should be introduced, back to back, slowly separated and turned in every direction; the bowel should be pinched between the finger and thumb until it becomes soft and patulous. This will take from five to ten minutes and should be done with great care so as not to tear the muscle or mucous membrane. When sufficiently dilated, he takes the knife and draws it through the base of the fissure, frequently in two places, the cut not to be more than one-twelfth of an inch deep which is sufficient to separate the superficial nerves. This converts a chronic into an acute sore. Then the bowels should be kept quiet for two or three days and the wound dressed as a cut ulcer, washing it every day with boracic acid and water or Packer's tar soap and water. If a laxative is needed, give a seidlitz powder or a teaspoonful of sodium phosphate in a glass of hot water. He says that in delayed healing, a few applications of nitrate of silver, 10 gr. to the ounce of water, carbolic acid one to three of olive oil, or balsam of Peru should be sufficient.

35. **Parasitic Origin of Eczema.**—After noticing the difficulties of defining eczema and the term "eczematization" invented by Besnier, Jadassohn says the questions regarding the parasitic origin of the disease are summed up in three questions, in substance as follows: 1. Are there eczemas properly so-called in addition to the morbid processes mentioned? 2. If similar processes not caused by pyogenic infection exist, are they of parasitic origin? 3. Are the microbes in eczematous skin, factors of this process? The author himself does not deny that certain varieties of eczema may develop without the action of the pyogenic micro-organisms. There are lesions in which, by the methods heretofore in use, one can not discover any micro-organisms to which can be attributed any parasitic relation. In these cases we must admit local and general predispositions not readily explained as etiologic factors. In these processes, as in many other diseases of the skin, we can very often determine the micro-organism invasion—staphylococcus and streptococcus. The results of these are dependent on the degree of virulence of the microbe, the local and general predisposition, and upon the nature of the original processes. A long series of very different reactions of the skin results, from slight irritation up to the grave and chronic eczema. These so-called infections can be produced idiopathically without the pre-existence of recognizable morbid processes. Their development and degree depend equally upon the nature of the soil—ordinary primary infections of the skin.

37. **Fracture of Cranium.**—The points made by McLean are: That it is injury to the contents of the cranium, not to the bones, that must be considered in these cases. There may be contusion of the brain without fracture of the skull. There may also be intracranial hemorrhage in simple nondepressed fracture of the cranium. Severe intracranial lesions may occur with very slight external symptoms.

38. **The Position of the Uterus.**—Robinson claims that in the typical normal position of the uterus with the subject in the erect attitude, the uterus should lie in the middle of the small pelvis so that the external os should be about on a level with the inferior border of the symphysis pubis and on a level with the plane of the ischial spines. The axis of the cervix lies in the axis of the pelvic curve and the anteflexion angle is about 80 degrees, with bladder and rectum empty or slightly filled.

43. **Asepsis in Obstetrics.**—First reviewing the mortality from puerperal sepsis and showing that there has been a vast improvement in this respect, Barnhill insists on the need of still further attention to the subject. The dangers of infection are far more to the puerperæ than to those who undergo the great majority of operations in general surgery. In the puerperal condition the absorptive surfaces for diseased germs are far more extensive, the glandular structures more active. The nervous system is more unstrung and the resisting power generally lessened. The avenues of infection are generally through unclean hands, unsterilized instruments, bed-dressings and unsanitary surroundings. Every parturition is essentially a surgical procedure, and until this is recognized

we will continue to have a high mortality. The physician should impress upon his patients the advisability of consulting him early so that he may see that the necessary preparations are made. Just as much care should be taken as if a surgical operation were in view. The hands should be thoroughly washed for several minutes in soap—preferably the green soap—and water; the nail brush should be used, the hands rinsed in alcohol to remove the fatty substances, then in a 2 per cent. solution of permanganate of potash, decolorized in a solution of oxalic acid, immersed in a 1 to 500 solution of mercury bichlorid and finally rinsed in sterilized water. Examinations should be made with the greatest care and not too frequently. All abrasions, etc., should be prevented if possible, and lacerations should be immediately repaired. The average physician shrinks from a surgical operation, fearing more from sepsis than from anything else, yet he does not hesitate to attend cases of confinement with only the most meager preparation. This is a defect which he hopes will be avoided in the future. He mentions some of the unsanitary conditions in country practice and the need of insisting on the greatest caution and care in this direction.

44. **Hematoma of Vulva and Vagina.**—Wright believes that this accident is of very rare occurrence, more so in country practice than in the city districts. He suggests that the influence of syhpillis upon the blood-vessels may have something to do with its origin. A disparity in the diameters of the pelvis and the child's head may also act as a cause. Veins are more frequently ruptured than the arteries, but he doubts that varicose veins are necessarily a preceding cause of hematoma. The dangers of the condition are considerable and may be greatly increased by hemorrhage, especially dangerous if it is internal. The danger is very great if it appears in the vagina in advance of the head during parturition. Delivery should be effected promptly regardless of complications. The forceps is to be preferred to turning, owing to the pressure it may have upon the torn blood-vessels. Early delivery also relieves the local pressure stasis that increases the hemorrhage. The after-treatment must be to look after the patient's general health and restore the loss from the bleeding.

45. **Puerperal Eclampsia.**—The obscurity in regard to puerperal eclampsia, its origin, prognosis, etc., are noticed by Sylvester. He considers the various theories of its causation and seems to favor the idea of the toxic action from deficient elimination, but whether it is entirely due to the kidneys and not any part to the other organs is particularly questioned. He suggests that eclamptic coma may be due to excessive amount of acetone which can be demonstrated in many such cases, and believes that probably not one but several substances combined may be the primary cause of the symptoms. In the treatment it is necessary first to stop the convulsions. In plethoric persons blood-letting should be resorted to sufficiently to reduce arterial tension, while if necessary it might be carried to the extreme and the effects mitigated by the subdermal use of large quantities of normal salt solution. Chloral per rectum is highly recommended, and some advocate the hypodermic use of morphin, the results of which are said by Veit to be unequaled by any other method. The most influence for good, whether medication is used or not, would be in emptying the uterus promptly at whatever stage the convulsions occur. Artificial delivery should be resorted to when the symptoms do not improve under medical and dietary treatment.

47. **Spasmus Nutans.**—Miller reports three cases of this rare disease of which he finds only eighty-four cases reported in the literature. He discusses its symptoms and causes and concludes that it presents a strikingly defined clinical picture which ought not be confounded with the many other conditions associated with it. It can not be a serious organic affection as it has a brief and favorable course and lacks the general deterioration accompanying such, which takes it out of that category. He refers to Ravdnitz' theory that it is of visual origin and analogous to miner's nystagmus, though he admits that this explanation will not apply to all cases. The nature of the affection is still very obscure and can not be explained by any one theory. He does not think the administration of bromid is so essential as are attention to the diet and hygiene and the use of drugs that will favor the general health and relieve any constitutional vice or temporary illness that may be present.

48. **Nasopharyngeal Disease.**—Huber discusses the subject of nasopharyngeal disease as related to pediatric practice and sums up that the removal of lymphoid hypertrophies with cure of the associated nasopharyngeal catarrh and regained permeability of the nose will make it possible to avoid many local pathologic changes, will improve the general health and mental faculties, the speech and hearing and the functions of taste and smell; reflex neuroses of various kinds will be modified or cured, and nasal and supposed pulmonary hemorrhages will disappear. Thoracic deformity will be relieved or cured. The tendency to acute rhinitis, laryngitis, pharyngitis and pneumonia is reduced. The dangers attending large cervical lymph-nodes will be avoided. Various infectious diseases are less likely to occur as well as meningeal infection from the nasopharynx, and ear complications in general.

55.—See also title 78.

60. **Serum Treatment of Pneumonia.**—Elfstrom reports experiments with a method of serum treatment suggested by C. and F. Klemperer. He applied two leeches to one case of croupous pneumonia and in the following eight cases only one leech on the forearm and after squeezing the blood out of the leech, he diluted it with from three to five parts of normal salt solution and heated it to a temperature of 60 C. for two hours. The mixture was then decanted and injected subcutaneously. In the majority of his patients the temperature fell to nearly normal. The patients seemed to be able to leave the sick bed earlier than he could have expected under other treatment. In one case the patient died without a lowering of temperature, and in still another patient, reaction was absent. The quantity of treated blood did not seem to have a deciding effect, but later in the disease a more decided action appears to follow.

65. This article appeared in The Journal of July 14, p. 79.

66. **Creosote.**—The use of creosote in phthisis is discussed by Potter, who, while he does not give up entirely the theory of the bactericidal effect of the drug, favors the idea that it acts more as a sort of tonic and increases the activity of protoplasm. Clinical experience at any rate shows us that the judicious administration of the drug is frequently followed by an improvement in appetite and digestion and better gastro-intestinal action. With these come improved nutrition, improvement in strength, retardation of local disease, and diminution of the secondary symptoms resulting therefrom. He gives it in smaller does than was formerly the case and does not find that guaiacol is a full equivalent. He has yet to see a case of pulmonary tuberculosis markedly benefited with creosote treatment without alimentary improvement. As long as the appetite and digestion remain good it may be proper to increase the creosote and continue the large doses for some time. Perhaps the best plan is that of Anders, to run up to pretty good-sized doses and then drop down to smaller ones again. He has not found it specially valuable in advanced septic stages of tuberculosis, and patients suffering from abuse of alcohol seldom bear it well. Antecedent or coincident diseases that seriously impair the digestive organs often, for that reason, interfere and contraindicate the use of creosote. We must, therefore, be careful not to impose on the impaired organs, and functions already weakened. To do no harm is one of the first rules of therapeutics.

67. **Adiposis Dolorosa.**—Dercum reports the autopsy of the typical original case of adiposis dolorosa reported by him in 1888. The clinical history is repeated in brief and the autopsy findings detailed. The most striking peculiarity was the small size of the thyroid gland, and microscopical examination proved it to be abnormal beyond doubt. T
observed were indicative partly of hypertrophy,
ous small acini which appeared to be in
ment. He thinks the findings are rather surpri
to explain, but it may not be impossible that
hypertrophy following general atrophy of the
also probable that there were other factors,

changes of function that played a part in the peculiar symptoms of this patient. He suggests as not inconceivable that, as a result of deranged thyroid action, some substance was thrown into the circulation which prevented proper oxidization of the hydrocarbons, and also acted as a cause of neuritis and nerve degeneration. There are some features, like diminished sweating, slowness of speech and mental irritability which suggest that other thyroid disease, myxedema. It is worth noting also that in two previous autopsies of adiposis dolorosa, which were not microscopically examined, both thyroid glands gave unmistakable evidence of disease.

78. See also title 55.

81. **Is the Anglo-Saxon Race Degenerating?**—Russell's article is a general discussion of the regressive tendencies of modern civilization. He thinks there are disintegrating processes at work which if carried on will destroy the moral and intellectual stamina of the race, but he has faith in the Anglo-Saxon stock and believes that there will be no such consequences.

82. **Excision of the Testicles.**—In the opinion of Peters, every case of advanced tubercular testicle should be dealt with by operation and if the disease has spread up the vas deferens and reached the vesiculæ seminales the whole tract should be ablated, preferably by the Roux operation. It should be the aim of the surgeon to remove every particle of the disease as thoroughly as in a case of carcinoma, though failure to do so is less disastrous since the resistance of the tissues to tuberculosis is very great. The patient should be placed under the same hygienic conditions as are favorable to recovery from tuberculosis in other parts of the body.

83. **Adenoids.**—Morton believes in the reflex effects of adenoids even in cases where hypertrophy is slight and mouth-breathing only occasionally present. He thinks operation should be performed in every case because of the evil effects of mouth-breathing, their consequences in the production in ear diseases, their making the children more liable to infectious diseases and keeping up a chronic catarrhal condition leading toward atrophic states in later years.

85. See abstract in The Journal, xxxiv, p. 233.

95. **The Insurance Examiner and Health Resorts.**—In no part of his professional work is the physician put to a severer test than in examining for insurance and he is, if competent, specially valuable to the company in health-resorts where the difficulties are far greater and the responsibility heavier than in other situations. Lankford notices disorders met with in these places, the necessity of extra careful examination for tuberculosis, nephritis, etc., and the other diseases like rheumatism, for example, which often seem to be retarded or suppressed in these localities. A special difficulty is the transient character of the population.

96. **The Heart in Life Insurance.**—Under this general heading Wilkins considers the sounds, rhythm, muscular condition, and diseases that may exist without evidence in the physical examinations. The most frequent of all cardiac symptoms is that of mitral regurgitant murmurs. Formerly this was considered a serious matter, but now we know that it may be comparatively harmless. If it occurs in a young man, as yet not completely developed, the chances are in favor of his reaching the expectation of life so far as the heart is concerned. When it is the result of disease past middle life there is greater danger. A quiet, easy life, with plenty of fresh air and the non-use of alcohol or tobacco are favorable as compared with an active worrying condition or dissipation. Aortic regurgitant murmurs are far more serious than is aortic obstruction. It is the cause of many of the cases of sudden death and consequently must be avoided by the insurance companies. In case of heart disease we must look for the causes of death in other members of the family. It is possible for organic murmurs to disappear temporarily or permanently and this should be remembered in the examination. Accentuation of the aortic second sound is to be regarded as of grave significance, especially when observed in a patient past middle life. Disturbances of the rhythm are comparatively frequent and may be purely functional, but may arise from some obscure and serious organic disturbance. He therefore thinks it is well to give the company the benefit of the doubt and throw out the risk. Intermittent pulse is not inconsistent with perfect health. Hypertrophy of the muscular substance of the heart without valvular disease is more frequent than is generally supposed. In young people without a change in the aortic sounds, it may or may not be of grave significance, but in advanced life it should be carefully considered. Of those diseased states in which nothing is revealed by physical examination, the best marked is angina pectoris, and where there is the least suspicion of this disorder the medical examiner should postpone accepting the risk. Cases of mitral stenosis or double valvular murmur he considers also too hazardous, as are likewise aortic cases even in the young. When functional murmurs appear, he thinks it advisable to postpone the acceptance of the risk for a few months unless the applicant be willing to accept a loaded policy. When it is associated with anemia he would certainly advise postponing, when due to other causes, a very slight addition to the rate will cover the extra risk. The occupation of the applicant has an important bearing. Excessive or increased blood-pressure and any occupation requiring it, with symptoms of diseased valves, should exclude life insurance ordinarily, but with a sedentary life, provided the applicant is not a speculator, who is to be dreaded as much as a hard-working man, the case is different. The clerk with the small income, which satisfies all his wants, although he may have a leaky heart, may easily reach his expectation so far as life insurance is concerned.

110. **Summer Diarrhea in Children.**—Porter believes summer diarrhea in children to be the same as cholera morbus in the adult. For the treatment in many cases simple stoppage of food will be sufficient; for prophylaxis, cleanliness. Diluting the food with water is indicated as the weather grows warmer, the system does not need so much in summer as in winter. When the attack is serious all food should be stopped from twelve to twenty-four hours and as long as vomiting continues. Use plenty of sterilized water and in a few hours give rice, barley and albumin water. If the vomiting has ceased, the child may be nursed for two to three minutes at intervals of not over four to six hours and have plenty of egg water or plain boiled water between times. For artificially fed children he would have all food sterilized and well diluted, and he says he has had as good success with condensed milk as with anything else except cow's milk, and sometimes better even than that. For the mechanical treatment he would advise flushing of the colon, especially if the fever is high, repeated every three to six hours, always using cold sterilized water; not more than one foot of pressure should be used, as there might be danger of rupture of the bowel, and it is easier to retain. He always begins treatment with laxatives; calomel in small doses is best, combined with sodium and salol to begin with until there is the characteristic dark stools, then large doses of bismuth subnitrate, pepsin and zinc sulphocarbolate, either in powder or solution, preferably the latter. It is not a bad idea to continue small doses of calomel, 1/20 gr. every four hours for a few days. Never use opium when it can be avoided, only in extreme nervousness or to protect the child from its mother, who is sometimes liable to hinder the treatment. In cases that have become chronic his ideal is zinc sulphocarbolate, or better, copper arsenite. He gives this, 1/25 gr., in two ounces of water, in teaspoonful doses every two hours, and finds it especially useful in these cases. Never begin treatment with astringents; use stimulants when indicated.

112. **State Legislation and Medicine.**—This article is of interest as showing up the state legislation of Texas. It gives an account of the New York Medical College of San Antonio, which graduated a negro field-hand in seventeen days, and where the professor of diseases of children is the 6-year-old child of the proprietor. The legislation which charters such an institution and makes diplomas from such legally chartered establishments the only requisites to practice, is shown up. He suggests concentrated action of the profession to bring about a better condition of things. The article was prepared before the charter of the New York Medical College was revoked.

FOREIGN.

British Medical Journal, August 11.

Prevention of Insanity. R. Percy Smith.—The increase of insanity is first noted by Smith, and the fact that in spite of all the attempts to show that it is due to the accumulation of senile cases and to a diminished death-rate, yet we have to admit that the condition is increasing. His statistics have already been noted in the report of the meeting of the British Medical Association (The Journal, xxxv, p. 511). He then calls attention to three items in particular, viz., propagation of the race by those of insane inheritance or those who have suffered from insanity. The question whether persons with marked heredity of insanity should marry is treated and the fact that in many cases family interests, ignorance, etc., force such marriages is duly noted. He thinks it is the duty of the medical profession to give sound advice to those who consult them in the matter, and not to lose sight of the fact that heredity is the largest cause of insanity, as shown by statistics. While there may be a doubt as to the marriage of persons of insane heredity, there can be no question as to the impropriety of it in cases where persons have themselves suffered from an attack. These marriages should be absolutely forbidden, and yet cases occur where persons have sinned against knowledge, as, for instance, physicians marrying their patients, etc. The question whether it is right for persons to beget and have children after having had an attack of insanity is also mentioned. The new civil code in Germany gives three years continuing insanity as ground for a divorce, but he questions whether this would be allowed in Great Britain, though he thinks, in spite of the objections to such an enactment, it would aid in putting an end to the reproduction of bad stock. It might be thought superfluous to comment on the iniquity of congenital imbeciles being allowed to marry were it not that this has occurred in many cases where large property interests were involved. Again marriage ought not to be permitted in case of chronic epileptics of any type. [The statement here made is a sort of reflection on the ruling families of the monarchical countries of Europe, and might bring the author under the penalty of *lèse majesté* in some of them.] The influence of alcohol on the production of insanity is shown by the author to be of importance, and similarly the relation of syphilis to general paresis. He believes that the latter should be considered a preventable disease and that if syphilis were controlled it would lead, to a great extent, to its disappearance.

The Lancet, August 11.

Structural Lesions in Urethro-Stenosis. Reginald Harrison.—Harrison's article on "The Remote Results of Structural Lesions—Interventions Sanglantes—in Urethro-Stenosis" ends with the following: The conclusions arrived at from the examination of structural lesions used in the treatment of urethral strictures may be summed up as follows: 1. That there is evidence to show that in peri-urethral strictures of the deep urethra the effects of divulsion as practiced in Perrève's and Holt's operations may be limited to rupturing the dense stricture bands in the submucosa of the urethra, while the mucous membrane itself escapes any serious injury or laceration and is merely restored by stretching to its original dimensions. Here a permanent cure may result. On the other hand where the mucous membrane is in itself the seat of stricture and forms part of the latter structurally, it is necessarily torn or lacerated by the process of sudden divulsion, and the pathologic condition consequently becomes assimilated with that of traumatisms of the urethra from external violence accidentally applied, which are followed by strictures of the most contractile and recurrent form. 2. That there is evidence to indicate that where the entire thickness of the stricture can be included within an incision of moderate dimensions made by an internal urethrotome the normal caliber of the urethra may be completely and permanently restored. Where this happens it may be concluded that all the fibers of contraction constituting the stricture were divided at the time of operation. And further that the converse is equally true. There is also evidence to show that the absence of recurrence under such circumstances is not necessarily dependent on the use of a bougie, though the latter is a precautionary measure which should invariably be advised. 3. That in the case of multiple stricture or strictures of the deep urethra of considerable dimensions either in their length or thickness treated by an internal incision of corresponding proportion, apart from other considerations, the tendency to recontraction and recurrence with an additional amount of cicatricial material, is frequent; the latter being probably due to the circumstances under which healing takes place in wounds of these dimensions so situated. 4. That lesions of the urethra demonstrate in various ways the poisonous effects that unprotected and unconfined urine is capable of exercising both on the body generally and on the tissues in contact with it, and that the liability to such effects is greatly diminished where drainage and irrigation render these conditions of the urine unlikely. 5. That in the case of recurring stricture previously treated by incision and in primary strictures of such length or extent as to require an internal section of corresponding size or as to which there might be doubt as to whether it would be safely possible so to include them, for the purpose of the operation and its results such wounds should be made with due regard to other surgical principles in addition to the one pertaining to the division of the contraction. 6. That there is direct evidence to show that the tendency to recontraction and recurrence of stricture after internal urethrotomy is largely diminished by the concurrent employment of systematic and efficient urine and wound drainage such as the combination of external urethrotomy, or perineal puncture affords.

The Indications of Thyrotomy. Felix Semon.—The indications of thyrotomy according to Semon are: 1. Foreign bodies in the larynx. 2. Injuries to the larynx. 3. Laryngocele. 4. Stenosis of the larynx. Acute laryngeal perichondritis. 6. Laryngeal tuberculosis. 7. Scleroma of the larynx. 8. New growths in the larynx; (*a*) Benign growths, and (*b*) malignant. In the case of foreign body there can be little divergence of opinion as to the propriety of first trying every possible method where practicable of removing it by the natural route, but he cautions that under no circumstances is it advisable to allow the foreign body to remain impacted in the larynx, no matter whether it produces serious symptoms or not. He has seen and recorded cases where such a course produced very serious consequences and, considering that thyrotomy is a comparatively safe operation in healthy persons, we should not hesitate to have recourse to it if any attempts at intralaryngeal removal failed. If the case were not suitable for this method we should not hesitate to perform thyrotomy with or without preliminary tracheotomy, according to the special needs of the case. In the case of severe fracture of the larynx by bullet-wounds, etc., the possibilities of thyrotomy to set matters right can not be questioned. In case of laryngocele where symptoms are threatening, thyrotomy followed by extirpation of the cysts would be indicated. In stenosis he thinks it is likely that this will be performed more frequently than it has been in the past. The recurrence of stenosis after intubation is a contingency which he thinks gives this operation a future, and particularly in cases of hypertrophic stenosis with enormous fibroid thickenings of the mucous membrane, excellent results may be obtained. The indications for thyrotomy in acute laryngeal perichondritis are likely to remain rare in spite of Schüller's recommendations; occasionally, however, it may be of use. In laryngeal tuberculosis the indications are that the operation is optional in circumscript lesions and preferable in patients whose general state of nutrition is good even if their lungs should be considerably affected. It is not desirable under opposite conditions. There is one serious drawback and that is the danger of tubercular infection of the wound. In scleroma of the larynx, thyrotomy, occasionally to be followed by methodical dilation, appears to be a sovereign operation. As regards new growths, especially benign ones, no external operation should be performed until surgery has unsuccessfully endeavored to remove it by the natural way. Still he thinks that one ought not to be too dogmatic and in individual cases no generally accepted canon should be the rule. In cases of multiple papillomata in children attempts at intralaryngeal removal ought to precede external operation, but unfortunately cases will occur where the conditions are unfavorable. Personally, he would in these cases be in favor of prophylactic tracheotomy, the child wearing its tube until it has grown up sufficiently to assist intelligently in intralaryngeal removal of the growths. Here we should remember the chance of losing the tube and death occurring. With malignant growths we have the most frequent and important causes of thyrotomy, and its results nowadays in really suitable cases are of more than encouraging nature. It is of the utmost importance that the diagnosis should be made in time. In those cases where the disease is still limited without infiltration of the glands, thyrotomy will be found to suffice not only for the radical extirpation of the disease but also for the prevention of recurrence. Semon claims to have succeeded in lastingly curing 83 per cent. of all the patients on whom he has operated. In very advanced cases, of course, no operation may be necessary and in some complete laryngectomy may be required.

A New Disease with a Specific Urinary Reaction. N. F. Surveyer.—The author describes the case of a young Parsee woman who suffered from a vesicular eruption and conjunctivitis, with febrile symptoms following an injury. He examined the urine and on adding a drop of strong caustic soda solution to the centrifugalized deposit, with a view to testing for pus, he found that the urine assumed a bright pinkish-purple in color. The precipitate was scarcely, if at all, soluble in any of the solvents tried. The reaction could be obtained by adding any other alkali and was obtained after more than five months. Heat did not destroy the reaction. On recurrence of the attack there was pain in the ear, but the eye was less affected than at the first attack.

He has not found this modified reaction in any other case, and since the patient has recovered, did not see it any further. He has never seen anything like it in 195 cases of urine analysis, but if carmine is added in due amount to healthy urine the reaction is at once obtained; this is soon destroyed by hydrogen peroxid. Tinc. chlorof. c., which contains carmine, had been given, and to be sure that the carmine had nothing to do with the reaction he availed himself of the opportunity afforded by the second attack when the drug was withheld, yet there was no difference. The blood was examined for the reaction with negative results. As regards the nature of the disease he abstains from making any observations at the present time.

Annales de Dermatologie (Paris), July.

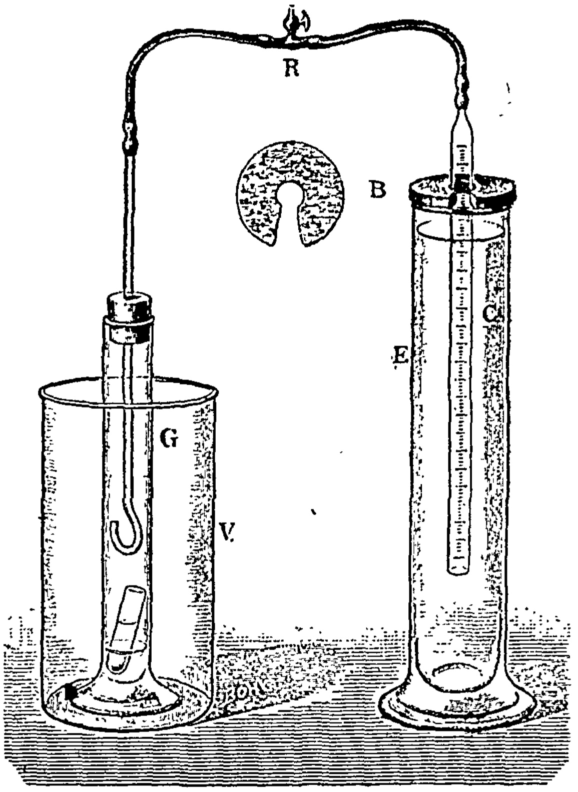
Improved Culture-Medium for Gonococcus. M. Sée.—Tubes of gelose are melted and cooled to 40 C. Half the volume of blood—drawn directly from the artery of a rabbit—is added to the gelose, and the tubes cooled slanting. The gonococcus develops on this medium more rapidly and luxuriantly than on any other. Characteristic colonies are evident in the first twenty-four hours, and retain their vitality for several weeks if not allowed to dry out. Bezançon and Griffon, who first described this method, have reinoculated cultures six months old.

Alloxuric Origin of Eczema. P. Tommasoli.—Hematopathology has discovered one constant element in every manifestation of eczema under all circumstances and in the most diverse subjects. This connecting link is uricemia. The alloxuric bodies—and uric acid in particular—are the cause of the affection, but they are not the only factors. Uric acid produces the disease, eczema; the other causes determine the variety. A communication from P. Gaston in the same issue summarizes the conclusions of seven years' study of the etiology of eczema as follows: Eczema has no existence as an entity, as a type of a skin disease. It is the expression of a disturbance in the nutrition of the papillary layer. The disturbance may be of parasitic or toxic, of external or internal origin, but the characteristic features, clinically and anatomically, are the signs of eczematization.

Chloric Acne. G. Thibierge.—Employees in electrical works are liable to an extensive acne induced by nascent chlorin. It especially affects those predisposed to acneic disturbances, although extreme cleanliness and cold weather may postpone its appearance. It does not differ clinically or anatomically from ordinary acne.

Bulletin de la Soc. de Pharmacie de Bordeaux, June.

Simplified Nitrogen Apparatus. G. Denigès.—Most of the apparatuses used to estimate the total amount of nitrogen in the urine are cumbersome, fragile and expensive. Denigès has modified his ureometer and claims that it is now possible to estimate with it both the urea and the total amount of nitrogen in the organic matters and fluids as accurately as with the most complicated instruments. It can also be used for the volumetric analysis of other gases, with manganese and lead carbonates, peroxids, hypochlorites, etc., merely adding some fluid to E less dense than water, that does not affect the carbon dioxid. The connecting rubber tube has an ebonized stopcock which allows communication between G and C and also the exterior, enabling the fluid in C to be brought to zero before the chemical action commences. The cork disc with the keyhole opening, B, used as a cover for E, acts as a spring to hold reservoir C. The opening in the disc is spread slightly apart with the left thumb and forefinger, thus allowing the reservoir C to be moved up or down as desired, while it holds the reservoir firmly when released. The detailed description of the original ureometer was published in the *Jour. de Méd. de Bordeaux*, of July 6, 1884.



Bulletin de l'Academie de Medecine (Paris), July 31.

Antitoxin of Pellagra. V. Babés.—It has been established that decaying corn contains a toxic substance which produces pellagra in certain localities, among the predisposed. Babés has further proved that an antitoxic substance is formed in the blood of persons, during or after recovery from pellagra, which possesses the property of annulling the toxic action of an extract of decayed corn obtained for this experimental research from regions where the disease is endemic. No other serum tested possessed this specific antitoxic property.

Sensitiveness of the Heart and Vessels. G. Pagano.—The venous portion of the vascular system, including the right heart, is practically insensible, while the arterial portion is extremely sensitive. The test excitation was made with prussic acid injected directly into the vessels and each half of the heart, the immediate effects alone being noted, to exclude the possibility of toxic action. The arterial tension was immediately increased to a marked extent when the substance was injected into the femoral artery, for instance. This reaction did not occur after removal of the abdominal sympathetic, thus demonstrating its nervous character. Pagano concludes from his research that the property of inducing at a distance actions modifying the statics and dynamics of the circulation is limited to the left section of the circulatory system, while the right—although it may respond to them—is incapable of generating them. He considers this sensibility of a sympathetic nature and that it is not the attribute of the capillaries alone, but also of the arterial trunks. This indirect or remote action may affect the entire organism or only certain regions. The sensory terminations—if this conception is correct—are nerve sentinels watching over the needs of the territory where they are stationed, ready to supply them before harm results.

Dourine, a Horse Disease. Buffard and Schneider.—These two young lieutenants in the French army in Algiers have succeeded in proving the etiologic identity of the dourine of Algiers with the "surra" of India and the "tsetse disease" of East Africa; they are all caused by a single trypanosoma, affecting horses and cattle. Dourine in horses is always propagated by mating and has never been known to affect a nonproductive animal. The symptoms are progressive anemia terminating in paraplegia, with fleeting circular patches on the skin, which remain flat, painless, non-fluctuating. The disease progresses insidiously to a fatal termination in four to ten months.

Journal des Sciences Med. de Lille, July 21.

Diabetic Myopia. Dujardin.—Two cases of diabetic myopia have been published recently and Dujardin has had occasion to observe a third. His case was a woman, 69 years old, with pronounced, chronic diabetes, who had used convex 4 D. glasses for reading. Her sight suddenly changed until she could read without glasses, while vision for distance was almost lost. The pupils resisted the mydriatic action of atropin, even a solution of 15 cg. in 10 gm. The idea of a spasm of the ciliary muscle seems more probable in this case than a physicochemical change in the lens as the explanation of the myopia. Paralysis of the muscle of accommodation might enable a hitherto latent hypermetropia to manifest itself. Horner has suggested that the presence of a large amount of sugar might result in the dehydration of the vitreous body, with consequent decrease in the size of the eye.

Nord Medical (Lille), August 1.

Pseudo-Coxalgia of Hernial Origin. Phocas.—When a child has a hernia, if dubious signs of coxalgia appear, the possibility of pseudo-coxalgia of hernial origin must be borne in mind and treatment commenced by curing the hernia. The child may limp and complain of pain in the hip-joint, but there is no atrophy of the member, and the muscular contraction is intermittent and subsides during repose. The movements of the joint are free except extreme abduction or flexion. There is no pain in the hip-joint on pressure at the classic points, and, finally, there is always hernia, although possibly unsuspected. The hernia becomes painful and produces an actual neuralgia of the cord. This neuralgia induces intermittent contraction and limping by reflex action. Phocas cites several instances in which a supposed coxalgia vanished completely after radical treatment of a slight and previously unnoticed hernia.

Presse Medicale (Paris), August 3.

Structure and Physiology of the Tonsils. M. Labbé.—Among the points emphasized in this communication are the important part played by the tonsils in hematopoiesis. The lymphocytes are transformed in them into mononuclear leucocytes with incessant karyokinesis. The antitoxic substances, oxidants and ferments secreted by the white corpuscles may possibly participate in the transformation of starchy matters in the mouth. The follicles of the tonsils by the extension of the epithelial surface are also a means of defense against microbian invasion.

Revue Hebd. de Laryngologie (Bordeaux), July 21.

Rapid and Effective Treatment of Fungous Otitis. A. Bonain.—"I cleanse, render antiseptic and anesthetize with cocained menthophenol. Then I remove with the loop or curette all the fungous growths and cauterize the raw surfaces left with zinc chlorid, pure or in a strong solution. After this I apply a gauze wick dressing and renew it every second or third day until all discharge has ceased." Bonain thus described his method, with which he has treated twenty-five cases of fungous otitis of the middle ear, among them one peculiarly chronic, rebellious case, cured in six days. Twenty days has been the average time required, with a maximum of forty-five in one complicated case. All but three have been cured or are still under treatment. These three have probably a lesion in the mastoid, but refuse operation.

Centralbatt f. Chirurgie (Leipsic), August 4 and 11.

Primary Carcinoma of Male Urethra. P. Rupprecht.—At the autopsy of a patient who had been operated on for primary carcinoma of the urethra nearly five years before, metastatic nodules were found in the lungs, and a carcinoma the size of a child's fist in the prostate, with involvement of numerous retroperitoneal lymph-glands. There had been no local recurrence and the patient had been in satisfactory health for four and one-half years, although requiring catheterization before and after intervention. He was 73 years of age at time of death.

August 11.

Necessity of Inflammation for Healing of Wounds. G. Meyer.—Modern methods of treating wounds neglect one of the most important factors in healing, *i.e.*, the natural reactionary processes of inflammation. We have learned that most of the benefits of antiseptic dressings are due to the slight inflammation they induce, and we know that absolute asepsis is unattainable. Meyer, therefore, claims that wounds should be rendered as aseptic as possible and then the preliminary stage of aseptic inflammation induced, to collect blood and leucocytes at the spot, so that the few invading germs that remain may meet their masters at once, even in the depth of the blood-clots, instead of finding conditions favorable for a culture-medium. He accomplishes this with tincture of iodin on aseptic, and aluminium acetate on infected, wounds. He considers treatment without inflammation absolutely dangerous in case of suppurating lesions on elderly or feeble persons. Thick dressings, holding the heat, to supplement the action of the aluminium acetate, attract the leucocytes and have proved very successful in his experience in such cases.

Advantages of Resection of the Pylorus. L. Rydygier.—Resection of the pylorus in appropriate cases, and not gastroenterostomy, is the operation of the future, according to Rydygier. He cites the history of one of his patients as a conclusive argument in favor of the former. She was operated on for ulcus pylori slightly encroaching on the pancreas, requiring resection of a portion of this organ with the pylorus. The operation was performed nineteen years ago, and she has since borne five children, the oldest now 17. She has done her own housework all these years and had only coarse fare to eat.

Dermatologische Zeitschrift (Berlin), August.

Pemphigus of the Conjunctiva. J. V. Michel.—This study of six personal cases of pemphigus of the conjunctiva concludes with the statement that systematic investigation of the mucous membranes and skin will usually disclose indications of pemphigus in all cases of adhesion of the conjunctiva not to be attributed to any evident cause, such as the action of caustics, trachoma or diphtheria. Pemphigus of the conjunctiva may appear at first in one eye, and become bilateral later. The prognosis is almost invariably bad. The process continues a progressive course as in other localizations. Boricized vaselin with cocain, or a plastic operation may be indicated. The success of the operation is usually annulled by the continuation of the pemphigus process.

Radiotherapy of Epitheliomata. V. Bie.—Sixteen cases of cutaneous epitheliomata have been treated with the chemical rays at Finsen's Institute, and seven have been completely cured. Another was cured, but has had a recurrence since. Five were improved, but not cured, and in three instances the treatment failed to produce results of any kind. One of the cases cured has been under observation for two and one-half years without recurrence, the rest from six to eleven months. Five cases had been ineffectually treated with vigorous measures before commencing the radiotherapy. Success is only possible when the epithelioma is superficial and accessible.

Transmissibility of Late Syphilis. O. Lassar.—A patient had acquired syphilis seventeen y [illegible] iously and had been thoroughly and apparently su [illegible] eat [illegible] married recently a healthy man who [illegible] She bore him a child in a normal [illegible] at three weeks presented all the symptoms of hereditary syphilis of the new-born. Another patient, infected seven years previously, was being treated for an ulcerating, gummatous lesion on the leg, when her healthy, six-months' infant presented unmistakable primary sclerosis of the labium majus.

Present Status of Radiotherapy. A. Loewald.—The writer reviews the reports published by Finsen and others in regard to the effects of treatment of cutaneous affections with the concentrated chemical or Roentgen rays, and concludes that they do not surpass those obtained with other methods. Their only superiority is the better cosmetic results, but with most patients the cosmetic benefits are out-balanced by the length and expense of radiotherapy. That the Roentgen rays have a peculiar and special effect on certain morbid conditions of the skin has been demonstrated beyond question.

Deutsche Medicinische Wochenschrift (Leipsic), August 2.

Diabetes Proved a Carbohydraturia. Rosin and Alfthan.—Baumann discovered that benzoyl chlorid combined with the carbohydrates—after decomposition with sodium hydrate—to form benzoyl compounds of the carbohydrates. It is possible to obtain by this means the total carbohydrates of the urine in the form of benzoyl esters. Rosin has been applying this fact to the quantitative estimation of the total carbohydrates in diabetic urine in comparison with normal, first expelling the monosaccharids by fermentation at 37 C. The research was conducted at Senator's clinic and many interesting results are hinted at, but this preliminary communication only announces that the benzoyl esters were found five to thirty times more abundant in diabetic than in normal urine. There does not seem to be any direct proportion between the amount of sugar and of the other carbohydrates. The results of the research seem to indicate that in diabetes not only the sugar, but all the other carbohydrates are increased in the urine, whether derived from the carbohydrates of the food or of the body or from the albumin of the food or organs. Alfthan concludes from special study of these benzoyl esters that the carbohydrates forming them are an intermediate product in the series of oxidations of the carbohydrate portion of the albumin molecule, and more particularly, of the organic glycogen, between the polysaccharids and grape sugar. He agrees with Rosin that this new research suggests that diabetes mellitus or insipidus is not merely a glycosuria, but an organic carbohydrate disease.

Future of Forensic Medicine. G. Puppe.—The writer of this article is superintendent of the "Investigation Prison" at Berlin, and his remarks are only intended for Prussia. He takes a gloomy view of the prospects of forensic medicine. In order to improve existing conditions he advocates that each medical graduate should pass an examination in this branch of medicine, after a special course which should include the legal questions involving the responsibility and rights of medical experts in criminal trials. The material for such courses should be derived from autopsies, which should be obligatory in every case of sudden death in which it is impossible to determine with certainty the cause of death, and in case of suspicious circumstances, even if no criminal proceedings are in view; also of suicides, of persons dying from cholera, plague, etc., of all unmarried women dying in the puerperium, and of all illegitimate children dying before the school-attending age. Further material would be afforded by examination of living subjects, claimants for damages, etc., and of blood-stained articles. The course would require a special institute.

A "Cured" Case of Diabetes Mellitus. Zaudy.—A man, 50 years old, was treated at Ebstein's clinic for pronounced, chronic and rebellious diabetes mellitus. The measures used were appropriate diet and four doses of salol on successive days. The sugar was reduced from 274.2 gm. to 50 gm. in 4570 c.c. urine in a month, and to merely traces by the end of the second month. There has been no recurrence during the year since.

Metatraumatic Alimentary Glycosuria. M. Haedke.—Twenty-five persons under treatment for severe traumatism with concussion, such as a fall from a height or serious injury to the skull, were tested with 100 gm. sugar to induce alimentary glycosuria the day after the trauma. Fifteen reacted positively, including two women.

Value of the Saccharometers in Vogue. A. Spaethe.—Comparative tables of the results attained with various tests and saccharometers demonstrate the superiority of Lohnstein's over Einhorn's and Fiebig's and the polarization test.

Milk and Salt in Severe Hemoptysis. E. Aronsohn.—Rectal injections of milk have been successful in arresting severe hemorrhage from the lungs, rebellious to all other measures, in several instances in the writer's experience. Eating salt has also proved useful in certain cases. One of his patients was attacked with recurring hemorrhage on the street, which was arrested at once by some salt obtained at the nearest house. It does not induce vomiting, but probably acts as an internal revulsive by the hyperemia it causes in the alimentary canal.

Variable Capacity of Morphin Syringes. H. Singer.—Twenty-nine morphin syringes were tested by Singer to determine their actual capacity and all were found to contain either more or less than the standard 1 c.c. Twelve were new from the factory and another dozen were borrowed from colleagues. The capacity varied from .865 gm. to 1.39, averaging 1.178. He suggests that syringes for subcutaneous injections should be officially inspected, as there is exceptional need for precision in substances thus injected into the system.

Wiener Klinische Rundschau, July 25 and August 5.

Treatment of Navel Infection. T. Escherich.—The importance of the umbilicus as a portal of entry for septic affections or as a local infectious focus is seldom fully realized. In 107 cases studied at Graz from this point of view, the evil consequences of a long, infected cord are conclusively demonstrated in tabulated statistics. They have convinced Escherich of the necessity of cutting the cord 3 cm. from the body as a routine measure. He uses the thermocautery for the purpose and then applies the band invented by Flick, which has a couple of tapes around the trunk and another around the back of the neck. The navel is inspected with ease as often as desired, without moving the child, by merely loosening the two tapes around the trunk and turning the bandage up. He applies dermatol or salicyl-talcum powder in most cases, but in gonorrheal affections has found aluminium acetate most effective, cauterizing with silver nitrate. In case of suspected tetanus the surface of the umbilical wound is scraped and a mouse inoculated with the scrapings. The tetanus was experimentally demonstrated in this way within twenty-four hours in several instances.

August 5.

Exclusive Milk Diet in Diabetes. A. Berger.—Five patients were fed exclusively with milk and kept in bed, two others were reliable out-patients, also restricted to an exclusive milk diet. The two cases of slight diabetes seemed to thrive on the milk and all sugar disappeared from their urine. The rest were chronic cases of diabetes and in each instance the amount of sugar in the urine materially increased under the influence of the milk.

Wiener Klinische Wochenschrift, July 19, 26 and August 2.

Post-Typhoid Suppuration of Thyroid Gland. A. Schudmak.—The writer explains the rarity of post-typhoid suppuration of the throid gland by assuming that some product of the gland usually renders the invading germs harmless. In a case he describes—about the thirteenth on record—the typhoid bacillus was found pure in the gland the ninth day after the first evidences of suppuration, the thirty-ninth after the first febrile symptoms. He states that the pyogenic property of the bacillus is not dependent on its virulence. He considers the leucopenia noted in abdominal typhoid the consequence of the localization of the disease in the principal leucocyte-forming apparatus and that it is not dependent on the virus of the bacillus. Whenever the latter locates at the periphery, leucocytosis is induced.

Iodin Intoxication the Cause of Basedow. R. Breuer.—In the course of a few weeks Breuer has had occasion to observe nine cases of "thyroidism," or of Basedow's disease, directly traceable to the administration of iodin. In some of the cases the symptoms were those of "constitutional iodism." The rest were secondary, and in one case primary Basedow's disease. The Geneva writers have also recently called attention to this same experience after administration of even small amounts of potassium iodid. The disturbance is probably due to the absorption of thyroid substance under the influence of the iodin, and the consequent flooding of the organism with it, which causes phenomena of intoxication—tachycardia, vasomotor disturbances, etc. These phenomena may be transient in some persons less susceptible than others, or they may become permanent by inducing constantly fresh congestion of the gland, thus forming a *circulus vitiosus*, which is manifested in chronic thyroidism, i. e., Basedow's disease. Goiter is extremely prevalent in Vienna. Breuer states that physicians residing there even for a few months have frequently noted that their necks became a little larger, requiring a larger sized collar. Possibly this local tendency may be an important factor in the frequency of the post-iodin thyroidism he has observed.

July 26.

Glycerin as a Vehicle for Antiseptics. O. V. Wunschheim.—The tests and experiences of the writer demonstrate that certain processes occur in 5 and 2.5 per cent. glycerin solutions of carbolic acid—either of a chemical or molecular character—which modify the acid in some way so that its disinfecting effect is completely lost. The addition of water restores this property. Diluting the 5 per cent. solution to make it a 2.5 per cent. glycerin-aqueous solution renders it as effective as the same solution without glycerin.

Artificial Interruption of Pregnancy. J. V. Braitenberg.—The particulars of twenty-two cases are tabulated in which delivery was induced for various reasons. One patient had applied for assistance in obtaining a living child, as her five previous children had died in the last month of pregnancy from no known cause. She was kept under careful supervision and when it was found that the fetal heart-beat and movements were becoming feebler, she was delivered artificially of a healthy child. This measure is recommended in case of habitual death of the fetus, as in this case.

Ferropyrin as a Hemostatic. E. Toff.—In sixty-five cases of gynecologic puerperal hemorrhage, the effect of ferropyrin in arresting the hemorrhage and favorably modifying the general symptoms was unmistakable in 90.7 per cent. of the cases. It is a mixture of ferrum chlorid and antipyrin, with none of the caustic properties of the former. It can be used freely on sensitive membranes.

Treatment of Necrotic Acne With Sea Salt. F. Luithlen.—Several cases of severe necrotic acne were treated by the writer with compresses impregnated with a solution of 1.2 per cent. solution of sea salt. This treatment was suggested by the improvement of a case during a course of sea bathing. The acne in each case had been treated ineffectually with the various remedies generally used, and the sea salt was a last resort. The effect was surprisingly favorable. The necrotic processes were arrested; the surface rapidly healed and there was no further loss of substance. In some of the cases salt baths were taken at the same time, but one was cured with the compresses alone. All were old, rebellious cases.

St. Petersburger Medicinische Wochenschrift, August 3.

Suffocation from Swallowing a Rubber Nipple. H. Lorentz.—A healthy 8-months' child was given a rubber nipple tied over a cork, which it sucked into the upper portion of the esophagus. It was tightly wedged and the entrance into the larynx was completely closed. Death occurred in fifteen minutes.

Influence of Frost on Peripheral Vessels. Zoege.—Rudintsky and the writer found in research on guinea-pigs that the more highly organized the tissue the more it is injured by frost. Cicatricial tissue takes its place and arteriosclerosis results when the process occurs in the vessels. The lesions occurring in the nerves at the same time are much less pronounced and less extensive than in the vessels under the influence of a freezing temperature, and it is evident that the vascular changes are not dependent on the nervous. Arteriosclerosis can thus be induced primarily without the participation of the nerves. This research also proved that exposure to cold, even months before, may entail disturbed nutrition in the part and consequent tardy gangrene.

Change of Address.

J. M. Brigham, Howell, to Kalamazoo, Mich.

J. W. P. Bates, 1830 Madison Ave., to 930 North Ave., Baltimore, Md.

Queries and Minor Notes.

MEDICAL LAWS.

To the Editor:—Will you kindly tell me something of the laws regulating the practice of medicine in New Mexico; also to whom should I apply?

Yours truly, J. F. S.

Answer.—A diploma, properly verified, from a medical college in good standing, is required as a condition for license in New Mexico. A four-year course and satisfactory preliminary educational requirements are necessary for recognition of a medical college by the board. Applicants for license must furnish satisfactory references of moral character and professional standing. Nongraduates or those without satisfactory diploma must pass examination. No licenses are issued to non-residents and no foreign diplomas are recognized. The secretary of the State Board of Health is Dr. T. P. Martin, Taos, New Mexico.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant General's Office, Washington, D. C., August 8 to 14, 1900, inclusive:

George F. Adair, acting asst.-surgeon, now at Fort Sheridan, Ill., to report to the commanding officer of that post for duty with the 5th Infantry, under orders for foreign service.

W. Edson Apple, acting asst.-surgeon, leave of absence granted, on the expiration of which he will report at San Francisco, Cal., for duty with troops en route to China.

Orlando Ducher, major and surgeon, Vols., former orders amended so as to direct him, on expiring of h f absence to report by letter to the Surgeon-C

Harry C. Gemmill, acting asst. nomas.

Ky., to accompany the 2d Infantry, under orders for foreign service.

Guy C. M. Godfrey, captain and asst.-surgeon, U. S. A., from the Department of Western Cuba to San Francisco, Cal., to accompany troops en route to Manila, P. I., where he will report for assignment.

Lewis A. Griffith, lieutenant and asst.-surgeon, 42d Infantry, Vols., now in San Francisco, Cal., to report in person to the Surgeon-General for instructions.

J. Randolph Harmer, acting asst.-surgeon, from Washington, D. C., to Fort Fremont, S. C., for post duty.

Philip F. Harvey, major and surgeon, U. S. A., from the Presidio of San Francisco, Cal., to Nagasaki, Japan, to establish a base hospital at that place.

John Van R. Hoff, major and surgeon, U. S. A., to proceed without delay to Taku, China, and report in person to Major-General Adna R. Chaffee, U. S. Vols., for duty as chief surgeon on his staff.

Alvis B. Kennedy, acting asst.-surgeon, former orders directing him to proceed to San Francisco, Cal., to accompany troops on foreign service revoked.

Thomas J. Kirkpatrick, Jr., lieutenant and asst.-surgeon, U. S. A., member of a board at Washington Barracks, D. C., to examine candidates for appointment as second lieutenants in the army.

Edward E. Lamkin, acting asst.-surgeon, previous orders amended so as to direct him to proceed from Baltimore, Md., instead of from St. Louis, Mo., to the Department of California.

Henry E. Menage, acting asst.-surgeon, now at New Orleans, La., to proceed to Denver, Colo., for assignment to duty at Fort Logan, Colo.

Edward L. Munson, captain and asst.-surgeon, U. S. A., member of a board at Washington Barracks, D. C., to examine candidates for appointment as second lieutenants in the army.

Arthur B. Smith, acting asst.-surgeon, from San Francisco, Cal., to the U. S. General Hospital, Fort Bayard, N. M., for temporary duty.

Bat Smith, acting asst.-surgeon, now at Fort Sheridan, Ill., to proceed to Wharton, Tex., for annulment of contract.

Albert E. Gruby, lieutenant and asst.-surgeon, U. S. A., relieved from the Department of Western Cuba and from further duty with the 1st Infantry: on expiration of present leave of absence to report at San Francisco, Cal., for duty with troops going on foreign service.

Benjamin B. Warriner, acting asst.-surgeon, from Fort Tremont, S. C., to San Francisco, Cal., for duty with troops going on foreign service.

The following acting asst.-surgeons to proceed from the places designated to San Francisco, Cal., for assignment to duty with troops destined for foreign service: Howard H. Bailey, Washington, D. C.; Louis Brechemin, Jr., Phildelphia, Pa.; William C. Mabry, Cleveland, Ohio; Clemen W. McMillan, St. Louis, Mo.; Robert E. Noble, New York City, N. Y.; Lorin B. Ohlinger, Alleghany, Pa.; Joseph A. O'Neill, New York City, N. Y.; Luke B. Peck, Brookline, Mass.; John A. Rafter, West Winfield, N. Y.; William Roberts, Washington, D. C.; J. Ralph Shook, Greencastle, Pa.; Charles A. Sturtevant, West Somerville, Mass.; Henry J. Watson, Ottumwa, Iowa; George Wilklow, Ellenville, N. Y.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending August 18, 1900.

Asst.-Surgeon M. K. Elmer, commissioned asst.-surgeon from July 18, 1900.

Surgeon C. H. T. Lowndes, commissioned surgeon from June 7, 1900.

Asst.-Surgeon W. M. Garton, detached from the *New York* and ordered to the *Massachusetts* immediately, temporarily, by the commander-in-chief of the North Atlantic Station.

P. A. Surgeons C. D. Costigan, G. A. Lung, J. T. Kennedy, ordered to the *Monocacy* for additional duty with regiment of marines.

Asst.-Surgeon E. Davis, ordered to the *Yorktown*.

P. A. Surgeon A. R. Alfred, ordered to the *Castine*.

Marine-Hospital Changes.

Official list of changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending August 16, 1900.

Surgeon J. H. White, to proceed to Jacksonville, Fla., as inspector; thence to proceed to Camp Perry, Fla., as inspector.

Asst.-Surgeon H. A. Stansfield, detailed by Chief Quarantine of the Philippine Islands as quarantine officer at Iloilo, P. I.: confirmed by Department approval August 15.

Asst.-Surgeon F. J. Thornbury, granted leave of absence for three days.

Asst.-Surgeon H. A. Stansfield, detailed by Chief Quarantine Officer of the Philippine Islands as quarantine officer at Cebu, P. I.; confirmed by Department approval August 15.

Acting Asst.-Surgeon F. C. McIsaac, granted leave of absence for fourteen days from August 3.

Hospital Steward B. E. Holsendorf, letter of July 20, 1900, granting Hospital Steward Holsendorf leave of absence for 30 days amended so that said leave shall be for 15 days only.

Hospital Steward C. A. Warhanik, relieved from duty at New York, N. Y. (Stapleton), and directed to proceed to Vineyard Haven, Mass., and report to medical officer in command for duty and assignment to quarters.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

SERUMTHERAPY IN CROUPOUS PNEUMONIA.*

J. C. WILSON, M.D.

Professor of the Practice of Medicine and of Clinical Medicine in the Jefferson Medical College.

PHILADELPHIA.

It is a matter of history that the diplococcus discovered in human saliva by Sternberg in 1880 and shown to produce in rabbits fatal septicemia, was found by Fraenkel a few years later to be almost constant in the rusty sputum of patients suffering from croupous pneumonia and in certain associated lesions. The confirmation of these observations by Weichselbaum led to the designation of this micro-organism as the "pneumococcus of Fraenkel and Weichselbaum." The rapidly following studies of Zaufal, Netter, Weichselbaum and others established the fact that the organism in question is present in the lesion of croupous pneumonia, the accompanying pleurisy, and in such intercurrent conditions as endocarditis, arthritis, middle-ear inflammations, parotitis, meningitis, pericarditis and others and in some cases of bronchopneumonia, orchitis, conjunctivitis and other inflammatory affections not necessarily associated with croupous pneumonia. It is, however, most commonly and closely identified with the last named disease.

The inoculation experiments of Netter in rabbits demonstrated the presence of the pneumococcus in the saliva of 20 per cent. of persons who had not had pneumonia, and in 82 per cent. of persons suffering from pneumonia. In the saliva of from 60 to 89 per cent. of persons who had passed through one attack of pneumonia, the pneumococci were shown to be virulent for varying periods extending over months and years—a fact which explains the common liability to subsequent attacks.

McFarland and Lincoln, who have recently written upon the subject, regard the evidence at this time as warranting the assertion "that about 75 per cent. of the cases of true croupous pneumonia are caused by the pneumococcus alone, about 15 per cent. by that organism in combination with the influenza bacillus, streptococcus, staphylococcus, colon bacillus, etc., and the remaining 10 per cent.—a very liberal allowance—by various bacteria other than the pneumococcus."

Netter found that in fatal cases the pneumococcus can be grown in cultures from the blood in the cavities of the heart. Kohn demonstrated it in 21.8 per cent. of a series of cases in the blood drawn from the veins of the arm, in patients suffering from croupous pneumonia, and concluded from an analysis of the cases that its presence in the blood adds greatly to the gravity of the disease.

Inoculation experiments have established the fact that intravenous or intraperitoneal injection of the pneumococcus does not give rise to pneumonia but to a general septicemia frequently associated with purulent pleurisy or pericarditis; while in some few instances the lesions of croupous pneumonia have followed direct inoculation of the lung through the chest wall.

These facts viewed in connection with the familiar phenomena of croupous pneumonia warrant the assumption that the disease arises from direct infection of the lung via the air-passages, the extensive exudate developing in the vesicles and terminal bronchi, and being, to use the phrase of Lambert, "practically outside of the body so far as the tissues themselves are concerned." The exudate contains the pneumococci in rich culture, and as Welch showed, in their most virulent state. Into the surrounding blood-vessels and lymph-spaces are poured the toxins produced, apparently small in volume, as separable products, but of great intensity, as shown by the common severity of the symptoms. The pneumococci, however, tend also to enter the circulation and cause a septicemia—a general pneumococcus infection of the entire body. The clinical picture is made up of the symptoms caused, on the one hand, by the mechanical disturbances due to the exudate, and on the other by those due to the toxemia, and varies as these respectively predominate. The gravity of any given case may be due to a massive exudate or to intense toxemia; but the fact must not be overlooked that the more extensive the exudate the more abundant the toxins produced. The variable virulence of the pneumococci in different instances may be invoked in default of other explanation to account for cases of massive exudate with comparatively mild general symptoms or limited local lesions with intense constitutional disturbances. General bacterial invasion of the blood in certain cases adds a new set of phenomena to those already present and serves to explain the gravest symptoms, distant local infections, exudative and suppurative processes and in many instances the fatal issue.

The knowledge of the bacteriology and pathology of croupous pneumonia, thus gradually acquired, has at each point of advance made it a more tempting field of investigation for the student of serumtherapy.

The worker in the laboratory here finds problems of the greatest intricacy, the solution of which gives promise of results of the highest practical value. The clinician awaits with eagerness this solution and the practical application of the results. The state of the subject at the present time is encouraging as to the future of serumtherapy in pneumonia.

The limits of this communication forbid any extended review of theoretical considerations. Suffice it to say that the earlier invest[illegible] Kl[illegible] and those who immed[illegible] experiments filtered cultures, cultures sterilized by heat or by antiseptics, glycerin extracts, etc., and produced an antitoxic serum; while the more recent workers, Washburn, de Rienzi, Pane, Lambert, and McFarland, have produced a serum by immunizing animals to increasing doses of live virulent cultures, until, as in the case of McFarland, a tolerance on the part of the horse to 100 c.c. of a very virulent culture has been established. These sera are anti-infectious. Lambert states that "the action of all pneumococcus sera which have so far been developed is to act within the blood-vessels and prevent a general septicemia, having apparently but little influence on the exudate." McFarland, on the other hand, expresses the hope "that the serum will be of use in the therapeusis of croupous pneumonia, exerting its effect upon the bacteria engaged in the pneumococcic processes in the lung, and that its immediate effects will be the reduction of temperature, strengthening of the pulse, production of an early crisis, and above all the prevention of the frequent accidental metastatic inflammations so common in the disease."

---

*Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

During the last four years a considerable number of cases of croupous pneumonia have been treated with antipneumococcus serum by different observers. On the whole the results are not discouraging, as regards the death-rate, the immediate effect on the symptoms or the course of the disease. De Rienzi reports a series of thirty-two cases with twenty-nine recoveries and three deaths. Numerous observers report improvement in the general condition and subjective sensations of the patients; lowering of the temperature and improvement in the pulse, without immediate crisis or shortening of the duration of the attack.

In February last Dr. McFarland placed at my disposal antipneumococcus serum prepared in his laboratory to be delivered fresh at such times and in such quantities as might be required for the treatment of cases of croupous pneumonia in the German Hospital in Philadelphia. The treatment has been carried out under my direction in a series of eighteen cases by Dr. Page, assistant physician to the hospital, and my residents, Drs. Moore and Uhle. I desire to express my thanks to these gentlemen for the interest and skill they have manifested in conducting the observations, and especially to Dr. McFarland for the opportunity of making them.

The extreme variations in the course of the attack and in the mortality of croupous pneumonia as modified by the age of the patient, his habits, previous health, antecedent disease and complications, render general statistics wholly unreliable in determining the efficacy of any plan of treatment. I therefore submit brief clinical histories of the cases, recognizing that the results can not be regarded as conclusive, but venturing to hope that as a contribution to the clinical study of serumtherapy they are not without value.

It is important to state that the serum was not used in these cases to the exclusion of other treatment. On the contrary, individual patients were treated in accordance with the usual plan in my service at the German Hospital, namely, by the systematic administration of Dover's powder; the application of ice bags to the affected region of the chest; the use of calomel, strychnia, alcohol, inhalations of oxygen when necessary, and such other symptomatic treatment as seemed judicious, in response to the indications in individual cases. The injections of serum were given in most instances directly after the patient's admission to the ward. In some few cases a delay of several hours arose in order that fresh serum might be obtained.

Case 1.—G. B., admitted Jan. 15, 1900, 23 years of age, single, male, Scotch, window-washer. Family history negative. Previous history: Scarlet fever in childhood; probably syphilis, alcohol in moderation.

The patient was admitted on the second day of the disease; his temperature was 103.4 F.; pulse 104; respiration 54. Onset sudden with chill and stabbing pain in right side of chest. Herpes on penis; crepitant râles and friction rub; tactile fremitus increased at right and left base. Pleurisy very marked. Signs of an effusion appeared on right side on the seventh day. Rusty sputum containing pneumococcus. Urine albuminous without casts, which disappeared before discharge.

Treatment.—Ice-bags to chest. Pulv. Doveri 0.3 every three hours. Serum started on fourth day of disease. Temperature 102.6 F.; respiration 36; pulse 104. Ten c. c. of serum was given hypodermically about every five hours. He received in all 19 doses, extending over a period of eight days. Temperature gradually lowered to 101 on the eighth day, then became septic and empyema was diagnosed. Transferred to surgical ward and operated upon.

Temperature not affected by serum but respiration and general condition improved after first few doses. Patient slept after nearly every dose. Blood counts were made before serum was given and daily afterward. It is interesting to note that *before serum was given the white blood-corpuscles numbered* 23,200. After three injections they were 42,400, and remained at this point for three days, when the serum was omitted for twenty-four hours, and the leucocytes dropped to 23,320. Upon resuming the serum the leucocytes again became 44,000. Patient discharged cured March 15.

Case 2.—F. C., admitted Feb. 19, 1900, aged 24 years, male, Italian, laborer. Family and previous history negative.

He was admitted on the sixth day of the disease. Temperature 101.2 F.; pulse 90; respiration 37. Herpes on lips; cough, painful in right chest. Dulness and tubular breathing over right upper lobe; crepitant râles at right lower lobes; impairment of resonance at left base. Heart—pulmonary second sound accentuated; no murmurs. Jaundiced on second day after admission.

Treatment—Ice-bags; pulv. Doveri 0.3; strychnia sulphate 0.002; whisky 15 c.c. every three hours. Serum treatment begun on eighth day. But two doses were given of 10 c.c. each. Temperature normal by crisis in twenty-four hours; no collapse. Uneventful recovery. Urine showed albumin and casts. No sputum or blood reports. Patient discharged March 7.

Case 3.—A. E., admitted March 4, 1900, aged 23 years, single, male, U.S.A., spinner. Family history negative. Previous history, smallpox.

He had been ill with grippe for three weeks. Three days before admission he had a chill and stabbing pain in right chest. Cough with rusty sputum. Tubular breathing; increased fremitus and flatness over base of right chest; a few fine râles; no friction rub. Sputum showed pneumococcus present. Urine showed albumin and casts; chlorids decreased. Blood examined on seventh day showed hemoglobin 55 per cent.; red blood-corpuscles 3,770,000; white, 12,500.

Treatment.—Ice-bags; pulv. Doveri 0.3; strychnia 0.002; whisky 15 c.c. every three hours. Serum begun on fifth day, evening. Temperature 101.6 F.; pulse 84; respiration 40. Six doses of serum, 10 to 15 c.c. each, about every six hours. Temperature normal in twelve hours. Treatment stopped. Temperature rose to 100 F. but returned to normal in two days without more serum. Recovered. Discharged March 19.

Case 4.—H. R., admitted March 4, 1900, aged 15 years, single, U.S.A., office boy. Family history: Mother, one brother and grandfather phthisical. Previous history negative.

Onset sudden with chill and stabbing pain in right chest. Cough with rusty sputum. Admitted fifth day. Temperature 101.2 F.; pulse 116; respiration 46. Base of both lungs dull posteriorly; dulness higher on left side. Increased fremitus; tubular breathing and râles over both bases; *no herpes.* Sputum showed pneumococcus present. Urine was albuminous; no casts; chlorids diminished. Blood examination, seventh day, hemoglobin 50 per cent.; red blood-corpuscles 4,250,000; white 8500.

Treatment.—Ice-bags; pulv. Doveri 0.3; whisky 15 c.c. every three hours. Serum began on sixth day. Six doses were given of 10 and 15 c.c. every five hours. Temperature 103.2 F.; respiration 38; pulse 104. Temperature normal on seventh day after five doses of serum were given. Recovered. Discharged March 18.

CASE 5.—W. H., admitted March 20, 1900, aged 39 years, male, married, U.S.A., salesman. Family history negative. Previous history: Tubercular testicle removed at German Hospital one year previous.

Present illness began suddenly with severe chill, great prostration, cough, rusty sputum, stabbing pain in left chest. Admitted second day. Temperature 103.6 F.; pulse 108; respiration 32. Tubular breathing over base of left lung posteriorly. Dulness increased. Fremitus, râles and marked friction rub. Urine contained albumin and casts; chlorids decreased .1 per cent. Sputum showed pneumococci; no tubercle bacilli. Blood showed hemoglobin 75 per cent.; red blood-corpuscles 4,290,000; white 16,000, third day.

Treatment was as usual. Serum begun at once, 9 doses of 20 c.c. each every three hours. Temperature 99 F. on sixth day. Serum stopped. Two days later patient became delirious, cyanotic and jaundiced. Right apex found solid and the seat of a well-marked pneumonia. Temperature 103.4 F.; respiration 52; pulse 120. Blood showed hemoglobin 71 per cent.; red blood-corpuscles 3,650,000; white, 20,000. Serum resumed as before, 14 doses of 20 c.c. each every three hours. Temperature normal in two days. Recovered. Discharged April 19.

Horse 628.—Bled Feb. 3, 1900, used March 20.

CASE 6.—J. VanD., admitted March 24, 1900, aged 28 years, male, single, Holland, laborer. Family and previous history negative.

Onset sudden with chill and stabbing pain in right chest; cough and rusty sputum. On admission, the second day of disease, temperature 104 F.; respiration 46; pulse 112. Entire right lung solid. Very delirious and cyanosed.

Treatment was as usual and oxygen every half hour. Serum not begun until third day. Three doses were given of 20 c.c. each every three hours. *No influence on temperature or symptoms.* Died in twenty-four hours.

Post-mortem confirms diagnosis. No other lesions found.

Horse 628.—Bled Feb. 3, 1900, used March 24.

CASE 7.—G. D., admitted March 27, 1900, aged 25 years, male, married, U.S.A., blacksmith. Family history negative. Previous history: Bronchitis three years previous; tobacco to excess; alcohol habitually in moderation.

Present Illness—Grippe for two weeks; recovery. Five days before admission had a chill and pain in left chest; cough, rusty sputum.

On admission, the sixth day of attack, the temperature was 102 F.; pulse 98; respiration 36. Great prostration; cough and pain; rusty sputum; herpes on lips. Dulness at base of left lung up to angle of scapula. Increased fremitus; tubular breathing; many râles and a friction rub. No friction rub heard in right lung over lower lobe. Sputum contained pneumococcus. Urine showed albumin and casts; chlorids normal. Blood—Eighth day, hemoglobin 75 per cent.; red blood-corpuscles 4,810,000; white 21,000.

Treatment was as usual. Serum begun on seventh day, five doses of 20 c.c. each, every three hours. On beginning, the temperature was 101 F.; pulse 88; respiration 32. The temperature became normal in twenty-two hours from beginning of serum treatment. Recovery. Discharged April 13.

Horse 628.—Bled Feb. 3, 1900; used March 27.

CASE 8.—W. B., admitted March 27, 1900, aged 42 years, female, single, Ireland, dressmaker. Family history—Sister died of phthisis. Previous history—Pleurisy seven years ago.

Present Condition—Grippe for two weeks before admission. Three days before admission suddenly taken with chill and pain in left chest, with cough.

On admission the temperature was 103 F.; pulse 120; respiration 40. There was cough with rusty sputum; pain in left chest; dyspnea; delirium; tenderness over gall-bladder; markedly cyanosed. Left lung expansion diminished; fremitus increased; dulness posteriorly over whole lung. Bronchial breathing; râles at end of expiration. Right lung edematous; numerous râles.

Blood examination showed hemoglobin 65 per cent.; red blood-corpuscles 3,890,000; white 8500. No urine report. Sputum contained pneumococcus.

Treatment was as usual. Serum begun on fifth day, six doses, 20 c.c. each, every three hours. All symptoms improved until the seventh day except pulse. Temperature suddenly went up to 105 F.; pulse 160; and death ensued on the third day after admission.

Horse 628.—Bled Feb. 3, 1900, used March 28.

CASE 9.—J. R., admitted April 4, 1900, aged 26 years, male, single, U.S.A., cigar-maker. Family history negative. Previous history—Enteric fever one year ago; tobacco and alcohol to excess.

Present illness began suddenly with chill and stabbing pain in right side; painful cough and dyspnea.

He was admitted on the *fifth day*. Temperature 103.4 F.; pulse 120; respiration 40. Herpes on lips; dyspnea; markedly cyanosed; delirious. Tubular breathing, flatness and increased fremitus over right lung except apex anteriorly. A few râles heard over both lungs. Friction rub over right lung. Blood count on eighth day of disease showed hemoglobin 75 per cent.; red blood-corpuscles 3,850,000; white 25,000. Sputum contained pneumococcus. Urine contained albumin; granular and hyaline casts.

Treatment was as usual. Serum begun at once on fifth day. Ten doses, of 20 c.c. each, every three hours. Temperature dropped to 100 F. in two days. All symptoms improved. Temperature ended by lysis, reaching normal on the fourteenth day. *Pleurisy continued, and signs of effusion at base of right lung* appeared on eleventh day and was absorbed before discharge. Recovery. Discharged April 25.

Horse 5597 G—Bled March 28, 1900; used April 4.

CASE 10.—J. F., admitted April 4, 1900, aged 30 years, male, Ireland, cigar-maker. Family and previous history negative. Alcohol at times to excess.

Present illness began suddenly with severe chill, pain in left side and dyspnea. Remained at home for two days without treatment, then walked to hospital. Admitted on third day. Cyanosed; herpes on lips; rusty sputum. Temperature 103.8 F.; respiration 42; pulse 128 and irregular. Lungs: Right lung, clear except for a few râles at base posteriorly. Left lung flat all over except at apex anteriorly. Pure tubular breathing and a few fine râles. Marked friction rub, heard best in axilla.

Urine showed albumin, hyaline and granular casts. Sputum contained pneumococcus. Blood count, fourth day, showed hemoglobin 75 per cent.; red blood-corpuscles, 3,730,000; white 28,000. Fifth day, hemoglobin 70 per cent.; red blood-corpuscles 3,780,000; white 20,000.

Treatment was as usual. Patient received serum, 20 c.c., every three hours and seemed to improve except that he was persistently cyanosed. After thirty-six hours, he became wildly delirious and died in that condition April 6 after a fit of screaming.

Horse 497 G—Bled March 28, 1900, used April 4.

CASE 11.—A. T., admitted April 19, 1900, aged 25 years, male, single, Jamaica, laborer. Family history negative. Previous history: Malaria several times; rheumatism twice. Syphilis. Alcohol in moderation.

Present illness began suddenly with fever and chill, stabbing pain in left chest, great prostration and dyspnea.

He was admitted on *fifth day*. Temperature 104F.; pulse 100; respiration 36. Intense dyspnea; no herpes; cough; rusty sputum; delirium; sharp pain over base of left lung. Left lung flat at base posteriorly up to angle of scapula; increased fremitus; fine crepitant râles at end of inspiration; tubular breathing.

Sputum showed pneumococcus present. Urine contained albumin, no casts. Blood, sixth day—hemoglobin 60 per cent., red blood-corpuscles 3,920,000, white 24,000.

Treatment was as usual. Serum begun at once, ten doses of 20 c.c. each every three hours. Temperature normal in thirty-six hours.

Patient developed an abscess in right thigh at seat of serum injections. Incised, drained; *healed rapidly*. Recovery. Discharged May 5.

Horse 736 B—Bled April 10, 1900, used April 17.

Case 12.—J. M., admitted April 21, 1900, aged 38 years; female, married, U. S. A., housework. Family history: One brother died of phthisis. Previous history negative.

Present trouble began two weeks before admission, with sore throat and other symptoms of influenza. Five days before admission she had a chill, with stabbing pain in left chest; cough. No rusty sputum or dyspnea.

On admission, sixth day, temperature 103.8F.; pulse 104; respiration 38. Cough, pain in left chest; purulent sputum, herpes on lips. Dulness anteriorly over right lung; increased fremitus and tubular breathing over upper lobe anteriorly and posteriorly. Râles over both lungs at upper lobes. Impaired resonance over upper lobe of left lung. Both bases clear.

Urine contained albumin, no casts. Blood, sixth day, before serum injections, hemoglobin 45 per cent., red blood-corpuscles 3,130,000, white 15,000. Three hours after first injection, hemoglobin 45 per cent., red blood-corpuscles 3,190,000, white 17,000.

Treatment was as usual. Three doses of serum, 20 c.c each, every three hours. Temperature normal in eighteen hours. Convalescence uneventful. Discharged May 2, recovered.

Horse 736 B—Bled April 10, used April 21.

Case 13.—J. W., admitted April 23, 1900, aged 19 years; female, colored, single, U. S. A., housework. Family and previous history negative. Present illness: Influenza one month previous. Recovered. Five days before admission taken sick again. Onset: vomiting and pain in right chest and abdomen. Two days later, chill, fever, cough, expectoration, sweating, pain in chest. On admission, third day, temperature 104.8F.; pulse 106; respiration 36; rusty sputum, intense dyspnea, restlessness. Dulness anteriorly and posteriorly over upper lobe of right lung, base clear; bronchial breathing; fremitus increased; râles over dull area.

Sputum showed pneumococcus present. Urine contained albumin; no casts. Blood fourth day, before serum injection, hemoglobin 55 per cent.; red blood-corpuscles 3,660,000; white 22,000.

Treatment as usual. Serum started on fourth day, 12 doses, 20 c.c. each, every three hours. When begun temperature was 105.4F.; pulse 120; respiration 40. Temperature normal in forty-eight hours. Recovery. Discharged May 10.

Horse 497 H—Bled April 6, used April 24.

Case 14.—R. B., admitted April 24, 1900, aged 19 years; male, single, U. S. A., laborer. Family and previous history negative. Present illness began sixteen days before admission with sudden onset, chill, headache, nosebleed, cough, bloody sputum, dyspnea and stabbing pain in right side. No herpes. Felt better the next day and went to work, but the following day all symptoms returned with greater severity and continued until admission. On admission temperature 102.6F.; pulse 116; respiration 34. Complains of pain on coughing and deep inspiration in upper abdomen; no expectoration; headache; dyspnea and malaise. Heart: Soft mitral systolic murmur; pulse irregular. Lungs: Right lung flat at base, extending laterally to mid-axillary line; impaired resonance at apex; vocal fremitus increased over apex anteriorly and posteriorly, absent over base posteriorly. Breath sounds absent over base posteriorly. Tubular breathing at angle of scapula. Fine râles heard. Left lung normal.

Sputum showed a few pneumococci. Urine contained albumin and casts. Blood three days after admission, before serum injection, hemoglobin 75 per cent.; red blood-corpuscles 4,030,000; white 4,400. Widal test negative.

Treatment was as usual. Serum begun the day after admission, three doses of 20 c.c. each, every three hours. Temperature normal in three days. Rapid lysis. Recovery. Discharged May 10.

Horse 497 H—Bled April 6, used April 26.

Case 15.—G. C., admitted April 25, 1900, aged 48 years, male, single, U. S. A., gardener. Family history negative. Previous history: Smallpox, enteric and scarlet fevers; alcohol and tobacco habitually.

Present illness began one week before admission with symptoms of grippe. Five days before admission had chill and stabbing pain in right chest; dyspnea; rusty sputum.

On admission temperature 102F.; pulse 112; respiration 36. Fifth day cyanosed with intense dyspnea; painful cough; rusty sputum. Heart: No murmurs; pulmonary second sound accentuated. Lungs: Consolidation of base of right lung; friction rub in axillary region. Sputum revealed pneumococcus. Urine contained albumin and casts. Blood: fifth day hemoglobin 50 per cent.; red blood-corpuscles 3,260,000; white 20,000.

Treatment was as usual. Serum begun on sixth day, three doses of 20 c.c. each every three hours. Temperature normal in nine hours. Recovery. Discharged May 9.

Horse 497 H—Bled April 6, used April 26.

Case 16.—C. W., admitted May 13, 1900, aged 34 years, male, single, U.S.A., show-man. Family and previous history not obtainable. Had been property man in Buffalo Bill's show for five years, during which time health had been good. Malt liquors in moderation. Weight about 200 pounds.

Present illness began eighteen hours before admission with a severe chill, pain in left chest and dyspnea.

On admission temperature 102.6 F.; pulse 120; respiration 50. Intense dyspnea; cough and rusty sputum; cyanosis. Pain in left chest. No herpes. Lower left lung solid; marked friction rub. Examination very difficult as any disturbance occasioned great cardiac distress. Urine showed albumin; no casts. Sputum had pneumococcus present. Blood: hemoglobin 76 per cent.; red corpuscles 4,390,000; white 15,000.

Treatment was as usual. Twenty doses of serum of 20 c.c. each, every three hours. Patient seemed to be improving but suddenly became very delirious, cyanosed and died very suddenly four days after admission.

Horse 497 T—Bled April 30, used May 13.

Case 17.—A. P., admitted May 2, 1900, aged 19 years, male, single, U. S. A., machinist. Family and previous history negative. Present illness began one week before admission with symptoms of grippe. Three days before admission was taken suddenly with chill; cough with rusty sputum and stabbing pain in left chest.

On admission temperature 105F.; pulse 124; respiration 50; delirious; very much cyanosed; no herpes. Heart: No murmurs; pulmonary second sound accentuated and metallic; pulse weak, quick and irregular. Left lung flat anteriorly and posteriorly all over. Tubular breathing everywhere except at base where for a few inches only harsh breathing and a few râles can be heard; fremitus increased; rusty sputum; no friction rub heard.

Treatment was as usual; 20 doses of serum given, 20 c.c each, every three hours. During the first twenty-four hours had to be stimulated nearly all the time. Right lung became very edematous and patient seemed to be dying. In forty hours the temperature reached 100F.; pulse 120; respiration 44. He seemed very much better and lungs began to clear. Temperature was slightly elevated for two weeks, probably on account of an abscess at site of serum injections, which was opened and drained, when temperature immediately became normal. Sputum revealed pneumococcus. Urine showed albumin and casts; at present only a trace of each. Blood: seventh day, hemoglobin 82 per cent.; red blood-corpuscles 3,430,000, white 37,000. Seventeenth day hemoglobin 60 per cent., red blood-corpuscles 2,890,000, white 21,000. Recovery. Discharged May 23.

Horse 736 B—Bled April 10, used May 3.

Case 18.—T. D., admitted May 11, 1900, aged 23 years, male, single, Wales, weaver. Family history negative. Previous history: Diphtheria and scarlet fever. Habits good.

Present illness began with sudden onset, chill, stabbing pain in right chest, cough, bloody expectoration.

On admission, fifth day, temperature 104F.; pulse 120; respiration 46; herpes on lips; rusty sputum. Lungs: Tactile fremitus increased. Tubular breathing and flatness over lower right lobe, posteriorly. Sputum had pneumococcus present. Blood: eighth day, hemoglobin 70 per cent.; red blood-corpuscles 4,150,000; white 11,000. Urine was albuminous, with casts; later, trace of albumin; no casts.

Treatment was as usual. Thirteen doses of serum, 20 c.c. each, every three hours. Temperature normal in forty-two hours. At that time the temperature was 99F.; pulse 92; *respiration 22. Recovery. Still in hospital.*

Horse 497 T—Bled April 30, used May 11.

Of the foregoing 18 cases 2 were women, 16 men. The youngest was 15 years of age, the oldest 48. The patients were all working people, most of whom had occupation up to the time of the attack. There were no tramps, coal-passers or sots among them.

Eleven of the patients were natives of the United States, one of Scotland, one of Wales, one of Holland, one of Jamaica, one of Ireland, and two of Italy.

One patient, Case 13, was a colored woman. The remainder were white.

In three instances there was a history of previous attacks of pneumonia.

One patient was admitted on the first day of the attack, 3 on the second, 2 on the third, 3 on the fourth, 4 on the fifth, 4 on the sixth, and in one instance the day of the attack was not ascertained.

The temperature upon admission varied from 101.2 to 105 F. The pulse frequency upon admission ranged from 90 to 128, and in 16 of the cases was 100 or higher.

Albuminuria was noted in 15 cases. In 9 of these cases casts of various kinds, usually hyaline, were also present, and in one, Case 14, blood was present in the urine.

Blood examinations were made in 15 cases, usually upon the day following admission; in some instances later than this. In 13 of the cases there was very marked leucocytosis. In two the leucocytes numbered 8500. In one of these, Case 4, the defervescence was complete twenty-seven hours after the first serum injection; in the other, Case 8, admitted on the fourth day of the attack, death took place on the seventh day. This patient, a woman aged 42 years, weighed over 200 pounds. The attack followed influenza.

There was a reduction of the red blood-corpuscles in all cases, usually moderate. The amount of hemoglobin was notably reduced in every instance, the least reduction being, in Case 16, to 76 per cent., and in Case 17 to 82 per cent.

Rusty sputum was present in 17 cases. In Case 12, admitted on the sixth day, the sputum was purulent.

The pneumococcus was reported to be present in the sputum of 15 cases. In Case 2, and in Case 6, no report was made, while in Case 12 it is distinctly stated that no pneumococci were found.

The summary of the dosage is interesting. In the earlier cases, it was given somewhat timidly, and at considerable intervals, the effect being closely watched. Later it was given freely and rapidly. In the first four cases the age of the serum, that is, the period that had elapsed from the time the serum was taken until its employment therapeutically, was not ascertained. In the subsequent cases it was known and recorded. The serum in all the cases was administered hypodermically. The total quantity varied from 20 c.c., in Case 2, to 460 c.c., in Case 5. Three cases received 400 c.c., or more. The administration extended over a period varying from six hours, in Case 6, to eight days, in Case 1. The age of the serum, as above stated, varied from seven to fifty-three days. The immediate effects were more favorable and more marked in recently-drawn serum than in that which had been drawn for longer periods. They consisted in general in lowering the temperature and pulse frequency, mitigation of pain and tendency to drowsiness. Several of the patients expressed themselves as feeling better after the injection and seemed to be anxious for the time when it should be repeated. There were no effects observed that could be ascribed to the trikresol present in the serum.

Of the 18 cases, 4 died, a mortality of 22.2 per cent. In two of the fatal cases, 6 and 10, no improvement followed the administration of the serum. In Cases 8 and 16, it is noted that slight improvement followed the earlier administrations of the serum, but that the later injections were without effect.

The defervesence was usually by crisis or rapid lysis. The duration of the attack varied from five to fourteen days, the majority of the cases coming to an end on the sixth, seventh or eighth day.

Of the 4 fatal cases, death occurred in 2 on the fourth day of the attack, in 1 on the fifth, and in 1 on the seventh. In three of these cases, 6, 10, and 16, the patients were alcoholic. In Case 8, no information concerning the previous habits of the patient could be obtained. In 6 of the cases that recovered there was a history of habitual excesses in alcohol.

The average duration of the stay in the hospital of 13 of the 14 cases that recovered, was 20½ days, one patient remaining in the ward at the time of the writing of the paper.

It is interesting to note that of 20 patients treated in my service in the men's medical ward at the Pennsylvania Hospital during the same period, on the same general plan, but without serum injections, 4 died, a mortality of 20 per cent. In this series, 8 of the patients, including the 4 fatal cases, were intemperate. No conclusions as to the effect of a plan of treatment can, however, be drawn from a limited series of cases.

DISCUSSION.

Dr. A. O. J. Kelly, Philadelphia—In connection with this important communication by Dr. Wilson I should like to report briefly for Dr. John H. Musser and myself, a single experience with the use of the antipneumococcic serum in the treatment of croupous pneumonia. A man, Charles D., 30 years of age, a native of Pennsylvania, and a lead-worker by occupation, was admitted to the Hospital of the University of Pennsylvania, to the service of Dr. Musser, March 9, 1900. He had been a hard worker all his life, constantly exposed to the inclemencies of the weather, and he had consumed alcohol to great excess. He had had at least two attacks of delirium tremens, and was reported to have been more or less under the influence of alcohol for a long time. On his admission to the hospital, it was ascertained that the patient had been complaining of cough and general malaise for two weeks. On Saturday evening, March 3, he went on one of his customary debauches, and continued drinking until the following Monday morning. On the evening of this day, March 5, he was taken with a severe chill, which lasted twenty minutes, but chilly sensations continued throughout the night. From this time until his admission to the hospital, he complained of pain in his right chest, cough, rusty expectoration, dyspnea, and fever. On admission to the hospital his temperature was 102.4 F., his pulse-rate 100, and his respirations 45. He was markedly cyanosed, revealed a blue line on his gums, and presented well-marked physical signs of consolidation of the right lung. There were also heard superficial to-and-fro friction sounds that were attributed to a concomitant pleuritis. The heart was negative with the exception of a systolic murmur at the base. Examination of the urine revealed a specific gravity of 1024. It was dark-amber in color, slightly turbid, and acid in reaction. It contained no sugar, nor indican; albumin was present in small amount; the chlorids were apparently normal. Microscopic examination revealed a few pus-corpuscles but no casts. Examination of the blood revealed hemoglobin 84 per cent., erythrocytes 4,300,000, and leucocytes 6770. The treatment instituted consisted of the local application of cold, the internal administration of carbonate of ammonium, whisky and strychnin, and a single hypodermic injection of morphin (1/32 grain). The following morning, with the exception that his respirations had increased to 56 per minute, the patient's condition had not changed. At 1 p. m., however, he became much worse, complained of extreme pain in the respirations had increased to 62 per minute. Physical examination of the chest revealed the signs of consolidation of the lower lobe of the left lung. Another hypodermic injection of morphin relieved the pain. Delirium, which was slight before, now became very marked, casts were detected in the urine, diplococci were found in large numbers in the sputum, and friction râles were heard over the pericardium. In view of the hopeless character of the case under ordinary circumstances, it was determined to try the effect of the antipneumococcic serum, which was very kindly placed at our disposal by Dr. Joseph McFarland. Injections of 20 c.c. each were given every three hours, commencing at 7 p. m., March 10. Only seven injections were given, because of the lack of serum. The leucocytes, which on admission had numbered 6770, just before the first injection numbered 17,360 per cubic millimeter. A half hour after each succeeding injection they numbered 16,420, 15,120, 19,420, 23,760, 24,520 and 29,400 respectively. At 6 p. m. March 11, they numbered 27,300, at midnight 28,200, and shortly before the patient's death, which occurred at 8 a. m. March 12, they numbered 33,400. The necropsy, which was performed by Dr. Flexner, revealed acute fibrinous pneumonia of the lower lobes of both lungs, extensive bilateral fibrinous pleurisy, chronic adhesive pleurisy of the right side, acute fibrinous pericarditis, acute splenic tumor, cloudy swelling of the liver and kidneys, slight atrophy of the cortex of the kidneys, moderate arteriosclerosis, and softening of the bronchial lymph-glands. I can not persuade myself that the serum was of any material value whatever in this case, but I admit that in view of the necropsy findings it is not likely that any treatment with which we are acquainted could have been of the slightest utility. The action of the serum, however, seems favorable rather than otherwise. The patient's general condition appeared to improve a little after each injection, but this may have been fanciful, as the pulse-rate and the respiration-rate gradually increased; the former reached 148, and the latter 72 per minute. Delirium also became active and ceased only a short time prior to death, when extreme exhaustion supervened. The serum, however, seemed to exert a marked influence in the production of leucocytosis. I am not unmindful of the fact that this may have been more apparent than real. It may possibly have resulted from the reaction of the body to the infection of the second lung, which became involved a short time prior to the commencement of the injections. But this is not likely. The treatment seems to merit further trial.

Dr. Delancy Rochester, of Buffalo—I rise to report a case in this connection of some interest because it bears upon the serum-therapy of pneumonia. About eight years ago, in the service of Dr. Charles Stockton, in the Buffalo General Hospital, there was a case of lobar pneumonia, and shortly after recovery another case entered the hospital. We were experimenting at that time and, with the permission of the patient, we blistered the convalescent patient and injected the serum thus obtained into the sick one. I do not remember the details of the case, but there was a decided improvement in the patient's condition for twenty-four hours. We were unable to obtain enough serum from the patient, but the evidence so far adduced in the use of the antipneumococcic serum points to the fact that we will yet have an agent of much value, when sufficiently concentrated, and when given in large enough doses. In the use of the antidiphtheric serum good results follow large doses, and I think the same thing will apply if larger doses of the antipneumococcic serum be used.

Dr. McFarland, Philadelphia—We found that small doses of the serum did but comparatively little good; it should be administered *ad libitum* until a large total amount of the serum is given. We are by no means certain as to the nature of the serum, and at present there is no accurate way of measuring its strength. The serum is prepared by administering living cultures of the pneumococcus to the horse. The pneumococcus is a difficult organism to cultivate, and its virulence is so quickly lost that one is never certain of the nature of the culture that he is administering to the horse. The best method by which the pneumococcus is kept virulent is by growing it alternately on artificial culture-media and in animals. The nature of the serum is uncertain. It may be antitoxic or antimicrobic, probably antimicrobic. While it is true that the serum of diphtheria and tetanus are specific for the respective diseases, there are proofs that the antipneumococcic serum is not specific for pneumonia but may be equally operative upon other microbic infections. I can cite for you an interesting observation made upon a horse which was immunized to the pneumococcus for four to six months, and one day received by mistake a large dose of the streptococcus culture. The dose should have killed it, but no ill effects followed. This leads me to believe that the serum is not specific for pneumonia alone. It is difficult to estimate the strength of the serum and it is natural to conclude that the number of theoretical observations made depend on the serums used and on their different strengths. The early observations on the pneumococcic serums are entirely useless. To administer 10 c.c. of serum from a convalescent patient is perfectly ridiculous; the patient is not getting any appreciable amount of the antitoxin. I have hesitated to use the intravenous method of injecting the serum, on account of the fact that the increased coagulability of the blood in pneumonia might lead to thrombosis. Later on we may find that this is the necessary mode of treatment. The serum should be fresh. Dr. William Park, of New York, urged that the serum should not be kept longer than six weeks, on account of losing its germicidal power. At the present time the whole subject is a very vague one, but the result of animal and culture observations indicates that the subject is one deserving much future investigation.

PSEUDO (?) OR MODIFIED (?) SMALLPOX.*

T. J. HAPPEL, M. D.
TRENTON, TENN.

The diversity of opinions in regard to the eruptive disease that has prevailed throughout the United States during 1899, has atracted much attention. My having had a personal experience with at least two hundred cases in one of the large counties of Tennessee (Gibson), and a nominal supervision of fully one hundred more as county health officer, has induced me to report this epidemic as briefly as possible. My sole object is to provoke a discussion, in which we should be deeply interested, as smallpox has been regarded with no favor by medical men.

SOME FEATURES OF VARIOLA VERA.

Before entering directly upon the phase of the subject presented in this paper, I desire to review briefly some of the chief characteristics of variola vera. It has been defined as an acute contagious and infectious disease, communicable at any time from the first rise in temperature to the final desquamation of the patient, and even after death, by the body itself in the dead-room, or by the effluvia of the corpse, when disentombed years after burial. It may be communicated by the urine or feces of affected patients, or by the small particles of the cuticle or scabs thrown off during the desquamative, or desiccative period. It has been rightly termed one of the most communicable of all the eruptive fevers.

According to Osler, one of our best authorities on the subject, "The contagium develops in the system of the smallpox patient, and is reproduced in the pustules. It exists in the secretions and excretions, and in the exhalations from the lungs and skin." . . . "Smallpox is one of the most virulent of contagious diseases, and persons exposed, if unprotected by vaccination, are almost invariably attacked. . . . There are instances on record of persons unsusceptible to the disease." He adds, further, that in the fearful epidemic in Montreal, in 1885, 86 per cent. of the deaths were of children under 10 years of age, when there died in that city, of smallpox, within nine months 3164 persons. He holds that the nature of the contagium of smallpox is still unknown, and that it is a little remarkable that in a disease which is rightly regarded as a type of all infectious maladies, the specific virus should still remain undetermined.

---

*Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Hartshorne, in "Reynold's System of Medicine," holds that the disease is communicable from the time of the initial fever till the last dry scale has disappeared; that in confluent smallpox the mortality is 50 per cent.; that in 2654 cases of the disease the mortality was 37 per cent., but that in this series of cases, the mortality in children under 5 years was 50 per cent., and from 40 to 60 years, 69 per cent., and from 70 to 90 years, 90 per cent.

Dr. Haygarth states that during his long attention to this subject, "Not a single instance had occurred to prove that persons liable to smallpox could associate in the same chamber with a patient with the disease without receiving the infection." "It is communicable in every way." "*A single breathing of the air is sufficient.*" "It is communicable from the moment of the initial fever." It has been caught in the dissecting-room from dead bodies that have been prepared for use on the table. I might thus continue to cite authorities showing the infectious and contagious nature of variola vera; its fatality—the death-rate varying from 25 to 45 per cent.—the fact that the disease is especially fatal when it prevails among negroes; that with all classes in the extremes of life—infancy and old age—the mortality is very great.

Other points upon which all authorities agree are: the date of the eruption—the third day from the initial headache, backache and fever—the fact that this eruptive stage lasts about three or four days, and that the eruption is first papular, then vesicular, then pustular; that in the vesicular stage the points of eruption become flattened, generally umbilicated, and slightly shriveled—this condition being followed by a state of euphory on the part of the patient; that on the eighth day of the eruption the contents of the vesicles become completely purulent, the eruption attains its greatest development and the vesicles become hemispherical and distended to their utmost, and the "suppurative, irritative or so-called secondary fever," begins, the temperature ranging from 102 to 105, or even higher; "that the mucous membrane of the mouth, fauces and larynx becomes most dangerously involved; that the vital forces of the patient are put to the severest test, and his life is placed in the greatest jeopardy"; that the cutis between the pustules becomes inflamed and the face, hands and feet swollen and disfigured far beyond that of the primary or eruptive stage; that pus begins to exude, and thick, yellow and dirty scabs and crusts form which, when removed, leave deep suppurating ulcers; that about the third day of the eruptive stage an intense itching sets in, and that this becomes almost unbearable in the suppurative stage when the crusts and scabs begin to loosen and fall off; that in the secondary fever we often have a muttering delirium; that it is frequently followed by deep-seated boils, and that most of the patients are left scarred and marked for life with pits at the sites of the points of eruption, especially on the neck, face and hands. These are points, as I have said, on which all authors agree.

THE EPIDEMIC AMONG NEGROES.

On June 1, 1899, I was called to Fruitland to see F., colored, aged about 35 years, supposed to have smallpox. I found the patient in one of the railroad section-houses sitting at a sewing-machine at work. I obtained the following history: In the latter part of April, or the first of May, a negro man came to the section-house from Mississippi, stopping in Jackson, Tenn., from one train to another, in a part of the city in which there had never been a case of smallpox. A few days after his arrival in Fruitland he became sick, went to bed in an adjoining house, and, "broke out," as the woman expressed it, "just as she was, but more so." She also told me he suffered before the eruption with headache, backache and fever; when the eruption appeared he was perfectly relieved from fever and pain, and in about two weeks was well and ready to go to work; that about the time he recovered, his wife became sick in the same way, only she was worse than he, and recovered in about the same time; that all of the colored inmates of the two section-houses freely mingled with these two cases, and that the white family, separated only by a fence, made no effort to maintain non-intercourse; that the head of the white family saw both of the sick negroes several times, and that the white children at the fence were frequently close to those who had just been in contact with the cases. None of the parties had ever been vaccinated; this fact I ascertained by an inspection of the arms. This woman stated that about four days before she was suffering with headache and backache, and called on her physician for something to relieve her; that finding some "bumps" on her face, he gave her some medicine and told her to keep in the house closely, as he suspected smallpox; that on the following day she was free from pain and fever, but that the bumps were still present, and that it was reported that she had smallpox; that she was not suffering at all, was, in fact, as well as she had been for months, and that there would have been no report or alarm had she not called for relief for her head and back, as her case was similar to the two reported, but much slighter. The eruption was found passing into the vesicular stage, with probably not more pain, and was at work, as has been stated. The disease was regarded as suspicious, and all the inmates of the section-house who could then be found were vaccinated, but the section laborers were away, and escaped vaccination at that time.

All were cautioned to remain on the premises, but were not quarantined or guarded. On June 21 I was again called to the section-house. I found a negro man about 30 years old with a confluent case of the eruption mentioned in the first case. He gave a history of headache, backache, fever, swollen face, hands and feet; eyes closed by the intensity of the inflammation; the papules discrete, but as numerous as possible; then, the vesicular stage, in which the blisters coalesced, forming large blebs, in many places larger than a silver dollar, with still larger ones on his hands and arms. Some of the blebs were fully 4x6. They appeared to involve only the most superficial layers of the cutis, and were unicellular. The patient did not claim to suffer at all, except from the natural soreness of the parts, blistered as they were. He had no fever, could have been up but for the condition of his feet, hands and buttocks. He was more comfortable lying down. He was then [illegible] seventh or eighth day of the eruption. A week [illegible] days later I saw him again. He met me at the [illegible] and claimed to be well. He had no secondary [illegible] i- any complications. To-day there is not a [illegible] so on his person, except some few stains [illegible] ed arms due to a deposit or accumulation of [illegible] on, terial in the skin. A few who were [illegible] had first visit had typical vaccin-sores. [illegible] hese caped the disease, the balance [illegible]

Dr. [illegible] Library

after case occurred in the two section-houses, never more than two at a time, till all but one or two had the disease. The two last seen by me were an old man, fully 70 years old, and a child about 4 years old. The old man's case was a reproduction of the second one, already reported, whilst the child's case was very similar to the first one. The child had been successfully vaccinated by me on June 2, and developed the disease in August. The old man gave an undoubted history of a successful vaccination in childhood.

July 23 I was called to a negro family in another neighborhood. This family had contracted the disease from a negro man who had visited the cases in Fruitland. He considered the disease of no importance till he had fully developed the eruption in the vesicular stage. Two families or more had then been in close contact with him. The family which I visited consisted of a man, his wife and three or more children. The two of the three children had had the disease in a mild form, leaving only maculæ on the cutis. If the youngest child had developed the disease, it was so mild that they did not discover it. The mother had broken out slightly on the Wednesday preceding my visit, which was made on Sunday. She was at church that day, just the fourth day from the date of the eruption. The man was then in the eighth day of his eruption. The points were conoidal, not at all inflamed around the base, and were discrete. He said that aside from the eruption, he was well; there was no fever, no loss of appetite. He had suffered from nausea and a decided sore throat. None of these parties had ever been vaccinated. On a subsequent visit I saw two families. In one, where the hygienic surroundings were good, the house being large and roomy, all the cases, some seven in all, had been very mild. None of these had been vaccinated, and not more than two at a time had developed the disease. In the other house I found a family of nine. The disease had existed in that house for a month or more, it having been contracted from the party who visited Fruitland. In this house two cases at a time was the rule. There had been six cases at the date of my visit, including the one just entering the eruptive stage. In some of these cases the headache, backache and fever had been severe and the eruption abundant, but after the first case no physician had been called, the mother stating that as soon as she discovered that she had to deal with a case of "the eruption" she felt easy, knowing that there was no danger. The mother claimed that she would not have the disease, as she had been vaccinated, but before the last case recovered she and the old grandmother, who had also been vaccinated, had a mild attack. Later on, in the same neighborhood, I visited a negress about 35 years old, who was suffering from the confluent type of the eruption. She gave a clear history of vaccination in her childhood. There were four children in the family. All were vaccinated, though in one or two there was "no take," yet all had the disease in a very mild form, the successfully vaccinated one having a severer attack than the baby under one year of age. In this settlement there were about forty cases. None were very sick; none were in bed for a longer time than four days, except the confluent case, which was confined for one week. When the disease first developed in this neighborhood, the first case, one of the severe ones, was visited by a physician, who carried his son, aged 4 years —who had never been vaccinated—into the negro cabin with him, where both remained nearly a half hour; neither contracted the disease. The fullblooded negro, except in one instance, alone suffered. In the excepted family, the negroes were almost white, and their attacks were very slight. Later on I vaccinated five of these children, of which number one had escaped in a large family. In this one the vaccination was successful, though he failed to have the disease, being exposed to it for at least six weeks. In another neighborhood, among families known as the Johnson families, there were about 30 cases—all black negroes. Two of these cases were confluent, the others discrete, being milder in proportion to the decreasing age of the subject. In one of these families three children, nearly grown, who had been vaccinated in March, 1899, escaped the disease, but the mother, who had a good vaccin mark, had a mild attack, and a daughter, who had never been vaccinated, escaped with not more than a dozen papules and vesicles. About one month after the complete recovery of two children in this series of cases, I vaccinated them. The result in one case was a typical vaccin sore, and negative in the other. I have reported now as briefly as possible the epidemic among the negroes.

AN EPIDEMIC AMONG WHITE PEOPLE.

On October 21 I was notified of the appearance of a case of the disease in one of the best white families in Fruitland. The source of infection was traced through a negro child. Her case proved to be a very mild, discrete eruption. On the eighth day of the eruption, when I saw her, she said that she was well, except the conoidal vesicular eruption. She had no fever, and from that day on desiccation progressed rapidly, and when seen on November 1, all of the eruption had disappeared, except the red elevated nodular base of the vesicle. On my first visit an effort was made to vaccinate all the members of the family. Some were conveniently absent from home. On November 1, I visited the family a second time, and found two new cases, the son, who had never been vaccinated, and a daughter with a typical vaccin sore, both mild, but the son much the milder of the two. Two other cases appeared, one that had been successfully vaccinated, the other not. The son who had the disease was afterward successfully vaccinated.

October 22, 1899, I was called to see J. H. A passing physician eight days before had called when he was suffering from headache, backache and fever, and when the eruption was just beginning to become vesicular, and had diagnosed the case as measles. The family suspected a mistake, and kept the case quiet. The report having gone out that the case was measles, those neighbors who had had rubeola visited the family, so that six families were exposed from the time of the initial fever till the date of my visit, several persons having been in the house and in the room after the eruption had become vesicular. My visit was made on the ninth day of the eruption. The patient was free from fever and sitting up in bed, able to eat all he could get; he said that he was well except the soreness of his hands, feet and buttocks. The eruption on his face was flattening and desiccating rapidly; that on his body was conoidal in shape, and filled with an opaque lymph; there was no pus, no itching nor other complaint.

There were ten inmates in this house at the time of my visit, besides the patient. All of these were vaccinated and notified that they must stay where they were or go to a pest-house. All were adults except one—a child of about eight months—five males and five females. Only two had been previously vaccinated—one in the sixties, the other before the war. The latter had a typical mark, well pitted; the other had a glazed cicatrix on the site of the vaccin sore. Every family that had been at all exposed was vaccinated—a total of thirty. Two days later I returned to see the patient, and found him rapidly improving. Five or six days later I founl typical vaccin sores on seven of the inmates of the house, but the remaining three had "no takes." The patient was out of doors, all crusts or scales had dropped, and nothing remained of his disease except red, elevated points, which had been the bases of the original papular eruption. On November 31 two members of the family began to suffer with headache, backache and a rise in temperature, two others with slighter pains and the baby became fretful, with no assignable cause. On November 5 a papular eruption made its appearance on five of the inmates mentioned, changing rapidly to a vesicular one. On Tuesday I visited the family and found the baby with not more than fifty points of a conoidal eruption, the mother with probably twice as many—vaccination having failed completely on these two—a discrete eruption scant on the remaining three, but much severer on the two young men. The three had typical vaccin sores of a week's duration. The grandmother, who had been vaccinated before the war, and on whom vaccination had again taken well, suffered most from the localized pain in the bases of the eruptive points. Of the three who escaped, two had been successfully vaccinated, the other unsuccessfully. One of these quarantined persons had left the place, deeming it safe to return home, as his vaccin had proved a perfect success, but on the same day, November 4, the initial fever developed, and on November 6, the eruption came out severely; but as soon as it fully appeared, he got out of bed and claimed to be well. None of the other inmates were confined to bed at all, except about October 28, when one of the young men remained in bed about thirty-six hours with a sick-headache and a sore arm. When I visited them, November 7, all were up and free from fever. Bear in mind that all of these parties, ten in number, were exposed from October 13, the date of the beginning of the fever of invasion, till October 22, the date of my first visit; that on this date they were all vaccinated; that on the 28th or 29th six of them had typical sores, and that no eruption appeared on any of them till November 5 or 6, just fourteen days from the date of vaccination; and do not forget that the mildest cases were the mother and child, on whom the vaccination did not take. Not a case appeared in any of the six families exposed. In every family, save one, there were some failures in vaccination; in one of these cases in which vaccination failed, the child had been exposed to the case several times during the febrile and early eruptive stage. On November 1 a case in another white family was reported, and was at once visited by me. In this case no contact could be traced with a case of this disease—exactly as it was reported by the patient J. H.

This last case, Mr. C., gave a history of fever, headache and backache, followed by an eruption, beginning on October 28, the fever subsiding on the appearance of the eruption. This man had never been vaccinated. The eruption was smaller and more irregularly shaped than in any of the other cases, and on the face, especially the forehead, it was almost confluent. On the arms and lower limbs it was discrete and conoidal. The eruption had not fully passed the papular stage on the hands and feet, though the vesicles had assumed an opaque appearance on the face. The patient was out of bed, with a temperature less than 100 F., feeling well, and ready to eat anything and everything brought to him. Five members of this family were vaccinated, after many threats and much persuasion, and four had the disease.

These cases are reported in as brief a manner as possible, and sum up about eighty colored and eleven whites.

AN OUTBREAK IN ANOTHER PART OF THE COUNTY.

About November 15, a new point of infection was reported in the county, in an incorporated town. I was sent for; I reported to the authorities that the disease was what we had had in the southern part of the county; that the State Board of Health called the disease smallpox; that I didn't consider it variola vera, but in deference to the health authorities, advised isolation and vaccination without quarantine. The first cases were, as elsewhere, negroes. The families were vaccinated successfully, and kept in their own premises, but every one of them developed the disease.

The local authorities next discovered the disease in a white family that could not account for its presence. These were detained for about fourteen days at home, but refused vaccination, and one-third of the family developed the disease, the later cases being milder than the first. No further efforts were made to prevent the spread of the disease, and it was reported that nearly every negro in the town had the disease, and not less than twenty-five whites, making in all about 100 cases, with no deaths; though one old lady 76 years of age died from congestion of the lungs while suffering from a very mild eruption. The disease appeared in the only hotel in the place, all of the proprietor's family being attacked, but business was never suspended, the traveling public being received.

In a country district just east of this incorporated town the epidemic held undisturbed sway. I was never called in; nor were many vaccinated. They preferred the disease to vaccination, so they reported officially to me. Here, too, the disease ran its own course, gradually growing milder, killing no one. There were forty or fifty cases in that district.

In another town three colored families became infected. After the first case all were vaccinated, except the babies, but not one escaped the disease, the mildest cases being the unvaccinated babies. In one family two cases of a severe type developed twenty-one days after vaccination, followed by a typical vaccin sore. Here there were seventeen cases, with no deaths.

At another point, in a family of twelve negroes, there was only one case, and this was not discovered till the fourth day of the eruption, which, while discrete, was severe. The family had been constantly in contact with this patient, but during the day lived largely out of the house. The man went to his work on the fifth day, and so continued till he was turned loose. He is now spotted, but the maculæ are rapidly disappearing. Living in another house was a family of three men, one woman and a baby. One of these men contracted the disease from the same source as the last case reported. All were successfully vaccinated except the baby. All had the disease, the baby in a milder form than did any of the others. These cases were at the county seat, and had been mingling with other negroes till the appearance of the eruption, and yet no other cases developed. In another negro family with the disease, all unvaccinated except the father and mother, this disease was so mild that the children were sent home from a crowded schoolroom during the vesicular stage of the eruption, and returned before desiccation and desquamation had been completed. I personally inspec [illegible] cases; only one member of the famil and that for only one or two hours, when they thought she had a chill. The vaccinated mother finally had the disease as severely as any of the others.

The disease finally ceased in the county, without any special efforts to check it, save the isolation of the families. There were in all about 300 cases, the large majority of them being negroes. In those cases where the whites contracted the disease they appeared to suffer more than did the negro. The last cases in the county were negroes who had had the disease in their families for weeks before it was discovered. When at last found out they were transferred to a house of detention. There on April 26, 1900, I visited in person and closely examined them. One man, who had contracted the disease on April 10 or 12, was nearly well. His was reported to have been one of the most severe cases. It was claimed that he had secondary fever, but this was disproved fully. His face was thickly marked with dark, almost black, spots. The next case, a colored male, a syphilitic, was in the eighth day of the disease. The scales were already dropping off. His face presented a variegated appearance. His nose was almost double its natural size. Crusts were abundant, but no thick scabs, and no pus anywhere. His temperature and pulse were normal. This was a severe confluent case. When seen he was very busy disposing of a full breakfast of rice. Of the fourteen cases in the house, not one was in bed. The cases ranged from two days to two weeks in duration; the patients were from 1 to 50 years of age. They were about equally divided as to sex. With this number in a room just before it had been aired and swept there was not the least odor. The eruption varied in size from a grain of wheat to a large vesicle. The cases of the children were mild in proportion to their ages. All were hungry. Not one complained of anything except of being detained in the house. There was no itching. It has been my experience further, in two large families, where all the inmates had been unrestrictedly allowed to mingle with the one case of the disease up to the fourth day of the eruption, to have had no case except the first in either family. One family, with the exception of two or three members, was successfully vaccinated; the other unsuccessfully. One was white; the other colored. In another family the only two members who had contracted the disease had had variola vera in their younger days—one being well pitted. The epidemic has shown a decided preference for the colored race, and the history of these cases has shown that it is more easily communicated from one to another among negroes than among the whites; but this is easily accounted for by the difference in their hygienic surroundings.

CHARACTERS OF THE EPIDEMIC COMPARED WITH SMALLPOX.

The points of similarity in these cases and true smallpox have been brought out in the clinical histories. There is in some the same backache, headache and initial fever, papular eruption, followed by the vesicular, then becoming opaque, but in the large majority of cases having none of the appearance of pus. These vesicles have in many cases flattened, but lacked the peculiar umbilication, and when full of opalescent fluid were conoidal, not hemispherical, in shape. There was no puckering around the eyes. None of them ever had creamy pus in them, and in no case was there ever an ulcerated surface left upon the removal of a crust. The vesicles, no matter how confluent, went through a process of desiccation, not of suppuration—only the epidermis and a few superficial layers of the cutis being involved. There were no crusts, only thin scales. In not a single case was there any secondary fever, the highest temperature on or after the eighth day not reaching 100 degrees, though the family physician reported secondary fever on the sixth day before the eruption had fully matured; with a temperature of 100.3 degrees. In no case at the time the secondary fever should have developed was there any inflamed margin around any of the so-called pustules, nor even in the confluent cases was there any inflammation about the skin after the eighth day. The cutis between the sores on the body and the extremities was normal in appearance, and there was no inflammation about the face or hands after that date.

In every case with the appearance of the eruption the fever subsided, and the patient got out of bed, and so remained, except in a few confluent cases mentioned, where the patients were more comfortable in bed on account of the condition of the feet and hands. After the eruption appeared the appetite returned in all of the cases. In not more than 5 per cent. of the cases was there nausea or vomiting. Itching was absent in nearly all, especially was this so in those patients whose skin had been kept clean. In not more than a half dozen cases was there any pitting, and in these few cases the marks were due to the patient rubbing off the vesicles to hurry up the process of recovery, as they supposed. In the few marked cases, the skin is rapidly assuming a normal appearance. The cases are chiefly marked by maculæ, in the negro, caused by an undue deposit of black pigment in what had been the base of the papules; in the whites this pigment is reddish or purple. This gives to the face a spotted appearance, but, as in the case of the pits, the pigment is rapidly disappearing.

Vaccination has not seemed to exert any protective influence whatever, but as so few of the negroes have been vaccinated, it is difficult to draw any conclusions on this point, but I would especially call attention to the results of my experiments in vaccinating those who have had the disease. In one instance, when two were vaccinated there were a "take" and a failure, and in the second lot, where five were vaccinated, one, who had escaped the disease through a period of six weeks' contact with it, showed a typical sore, and another one a slight "take." Again, in parties who in childhood had been vaccinated, two of them had a confluent attack, and in at least two instances, children who had been vaccinated about one month previously contracted the disease. Lastly, where of ten vaccinated persons, with seven typical sores developing six days after vaccination, and where three of the same lot of cases entirely failed to "take," fourteen days after the vaccination and seven or eight days after the appearance of the vaccin sore only three had escaped the disease, one of these being one on whom vaccination had no effect, and the two mildest cases of the eruption being the baby and wife of the first case, the two having failed to show any vaccin sores at all. Again, two cases with vaccin sores twenty-one days old had severe attacks of the disease, and still again, of a family of ten persons, all of whom were vaccinated at the development of the first case, not one escaped the disease; and there was a duplication of this in another family. You answer that it has frequently been reported that parties who have had smallpox have been successfully vaccinated. "It is to be observed, however, that the smallpox has been experienced, in most cases many years before."[1] It is admitted by all that the more recent the vaccination, the more protective it is. Yet I found persons vaccinated a month and those vaccinated two weeks before the appearance of the disease equally affected. In my last series of cases, one that had a typical cicatrix, and was again vaccinated successfully, with the vaccin sore fully matured, conditions in which, according to Dr. Hare, protection is most easily afforded, had just as severe an attack as did any of the others in the house. The primary vaccination should have perfected it, yet the disease appeared, while one who had never been vaccinated, and on whom vaccination had failed in this group of cases, escaped.

---

[1] N. Y. Record, July 5 and 26, 1879.

Smallpox is communicable in every stage of the disease, while this disease becomes communicable only in the late vesicular, opaque lymphoid or pustular stage. This fact has been demonstrated in every case with which I had to deal. I have already cited families exposed in my last cases. Is this disease that has been so widespread true variola, such as we have met with for years—a disease having a death-rate of from 25 to 50 per cent., while this has none?

I find in examining medical works of old as well as recent dates but little reference to any eruptive disease corresponding with this. In Good's Study, published in 1829, Mr. Marshall reports what is called Kandayan Epidemic. While several cases made a near approach to varicella, all of them so far deviated from the ordinary character of the variolous secretion as to be devoid of a creamy and consistent pus, and rarely exhibited more than a whey-like matter, whether the eruptions were distinct or confluent, or the fever mild or severe. In other respects, Mr. Marshall observes, "the disease did not materially differ from the description given of the smallpox by systematic writers." These were mostly cases that had been preceded by vaccination.

Van Swieten has described a spurious or bastard variola under the name of *Steen-pochen* (Stone-pox), which he claims to have seen as frequently epidemic as the genuine variola, indeed, running apace with the latter, and sometimes succeeding it.

Reynolds,[2] under the head of "Variola Benigna," refers to Van Swieten's description "of natural smallpox under the title of Variola Verrucosa, or Cornea, Stone-pock, horn-pock and wort-pock, which we sometimes see in these days, and in which the disease is of a mild, modified character." He says: "These are examples of a mild, natural smallpox, such as have occurred no doubt at all periods to a few favored individuals, and in which, fortunately for the subjects attacked, the disease leaves no trace behind."

CONCLUSION.

Can this disease be called variola vera? The initial fever, backache and headache are the same, but all eruptive diseases have the same train of symptoms to a greater or lesser degree. In a large per cent. of cases of variola in this stage we have nausea and vomiting, with an inflamed condition of the mucous membrane, whilst in this epidemic this state of affairs has been the rare exception. In variola the eruption is, as a rule, more regular in its development. In this I have seen cases as late as the sixth day with vesicles still appearing. In variola the eruption is, as a rule, in the pustular stage, hemispherical; in this, in the third stage, conoidal in almost every case. In smallpox the rule is that the patient begins to fight for his life on the eighth day, but in this he begins to recover. There is no suppurative stage, but a stage of desiccation, and when the scales are removed by force there are no ulcerated bases seen even in the confluent cases. This eruption has never in a single case been followed by boils or phlegmonous swellings, which are too common in smallpox. Smallpox is prevented by vaccination, this is not, nor even, so far as my experience and experiments go, modified, as I have seen milder cases in the same house among the unvaccinated than among those whose arms had a vaccin sore, 8 or 10, or even 21 days old. Smallpox, as a rule, stamps its indelible imprint on its victim; it is the exception to find one "pitted" with this disease, and when pitted at first, the skin rapidly becomes smooth. There is no mortality in this disease, but in smallpox about one-fourth of the cases die. In this disease there have been neither complications nor sequelæ, but in smallpox they are the rule. In the cases which I have seen, and they have been many, not a dose of medicine has been given. Nature has not been interfered with, and all have recovered, whether in the hovel, hut or comfortable house.

You ask what I call the disease—I answer frankly that I do not know.

DISCUSSION.

DR. J. J. WALSH, New York—It must be remembered that the great Vienna school of dermatologists have never admitted that there is an essential distinction between varicella and variola. Prof. Senator, of Berlin, said not long ago that while at first in his medical career he held with the Vienna school in this matter, later he came to disagree with them, and yet now goes back to his former opinion and thinks the two diseases have some very intimate connection. In Berlin, when an epidemic of varicella appears, Prof. Senator always looks for a true case of variola somewhere in the vicinity.

Dr. Happel's observations, so carefully made, are very valuable as showing, perhaps, an intermediate stage between varicella and true variola. In children-hospital practice it is possible to have with varicella, severe fever, 104 F., perhaps, and, after two or three days, umbilicated vesicles, pustulation and minute pitting, very much resembling smallpox. The study of the two diseases, and especially of cases that seem to occupy a place between them, is most interesting. Dr. Happel is to be congratulated on the faithful observations he has made and on his delay in making a diagnostic conclusion until he was assured of the true character of the disease he had to deal with.

DR. JAMES, Missouri—I was much interested in the paper, because in Missouri we have been enjoying this epidemic in a somewhat exaggerated form. We have been fortunate enough in having but few deaths from variola, or discrete smallpox. In our state we have had to fight for an opportunity to demonstrate the benefits of vaccination. We have also had an opportunity of demonstrating the peculiarities of some of the medical profession, and the mistakes of a great many of the profession who depend too much on their knowledge as clinicians. We are called to see a case that is supposed to be smallpox or chickenpox and we, on the impulse of the moment, diagnose the case, possibly in the stage of desquamation or inflammation. It is chickenpox. We are too bigoted and too bright to acknowledge our error; it is chicken-pox and the whole locality is so informed. In the western portion of Missouri several thousand cases of this form have appeared in certain localities, and the board of health of which I have the honor to be a member has been invited to pass upon the disease. In one locality, in a town of 15,000 or 20,000 people, I was informed that the disease prevailing was chicken-pox, passed on by men of vast experience in that disease during the Civil War. The locality begged for help. I called and found that this town had from 150 to 200 cases of discrete smallpox, with possibly 4 or 5 cases of the confluent form. In another locality there was a case which was brought to Kansas City; immediately I was invited to visit the case. I isolated it and vaccinated the people who had been [illegible] [illegible] [illegible] that we had no further development of [illegible] [illegible] locality.

---

[2] Reynolds: System of Medicine, 1880, p. 32.

Dr. Chapman, Ohio—In Ohio during the last year or two, there has been quite an epidemic of this disease. I have also had to contend with the doctors in regard to the name of the affection. In some communities, hamlets or villages where I have personally inspected the patients, I have found 30 in a population of 102 in bed with the disease. In the majority of cases they were adults and very sick. A great many cases occurred in those who had been vaccinated and who bore the well-known marks of pseudo-vaccination. None of them had been vaccinated recently or had any mark of recent vaccination. I wish to call attention to one point. The disease varicella or chicken-pox is not a disease of adult life. It is a disease rarely found in adults. I beg to differ with the writer of the paper regarding his views. I have failed to see a case develop where vaccination had run its course. I object to vaccination after the disease has developed five or six days, because you then would have two diseases running. I do not believe that this is varicella. Formerly varicella and variola were considered alike. In a community of 102 there were 4 deaths from this disease. I believe that if it be left to run rampant there will be more deaths. I believe that if we, as health-officers, do not do our best to isolate the cases and vaccinate the community we shall get a severe epidemic of smallpox such as has never been seen. The majority of doctors have never seen a case of smallpox, and yet they know more about smallpox than those who have.

Dr. Corlett, Ohio—Twenty years ago I studied smallpox in London, and since that time I have studied the disease in various countries, and especially in this country and in the State of Ohio; we get different epidemics, differences in virulence and in clinical features. That is well recognized by all writers on this disease. During the past few years we have had in the State of Ohio a visitation of smallpox, which first started in a small town from an alleged case of chicken-pox. From those few cases the disease has gradually spread over the whole state. In Cleveland we have had a great many cases, hundreds of them, and during this time I have taken the occasion to make photographs of the disease, which I hope to exhibit to another section, showing the differential diagnosis between smallpox and chicken-pox. In Cleveland we have had a number of fatal cases; we have had an opportunity of showing the value of vaccination. I believe that many cases of supposed vaccinations, reported as typical vaccination marks, were due to other pathogenic organisms gaining access. When tubes are used with proper antisepsis a typical lesion occurs and it is devoid of the formation that is so common in a more careless vaccination. I am still of the opinion that we have chicken-pox and smallpox, which differ in severity, and that vaccination is the only safeguard against smallpox.

Dr. Woodruff, Ohio—I know vaccination is a protection. I know of one family of eight people, a dirty, filthy family, all had the disease but the mother and she had been protected by vaccination. I know of another family, where a young man, well to do, had a case of smallpox; he had the pustular form, with much fever, and he was very sick. In that family there were three others, two sisters and a mother, who were protected by vaccination and none of them took it. The stand taken is wrong, for we know that from the disease occurring in a town the whole country may become infected.

Dr. Stewart, Philadelphia—In an epidemic a few years ago in Philadelphia we had as high as 255 deaths in one week from smallpox. There was no mistake about the diagnosis of the disease at all. Any man who went through that epidemic can not fail to recognize the differences between varicella, varioloid and variola. They are as distinct as can be. There could be no mistake in diagnosing the three forms. In regard to the paper read here I do not think from the evidence given that it is any form of variola at all. It comes under eruptive diseases, of course, but I should think it was some form of vesicular exanthem of some kind, due to climatic conditions.

Dr. McCormack, Kentucky—The cases from Tennessee were cases of genuine but mild smallpox, and may have been the cause of the violent outbreak that occurred there where the death-rate was 60 per cent. [Dr. McCormack then moved the resolution which was published in the official minutes of the Section in The Journal, June 23, p. 1630.]

Dr. T. J. Happel, Trenton, Tenn.—I think the resolution is a gross injustice. Dr. McCormack never saw a case of the disease coming from Gibson County, and no case of the disease has been reported as going from Gibson County into Kentucky and none of the Kentucky or Ohio authorities know anything about these cases. I consider a resolution of that kind a gross injustice.

Dr. George Dock, Ann Arbor, Mich., Chairman—The resolution is out of order.

Dr. Happel (continuing)—I must say that many have misrepresented the intent of the paper. I have nowhere argued against protection against variola. Ninety-five per cent. of the persons living in my town were vaccinated under an enforcing ordinance drawn up by myself. Taking the position that I have in the paper, I wish to say that I have no axes to grind. I have succeeded in doing what I expected to do. Personally I have this to say. My first experience in the practice of medicine was with smallpox, and I have met with it time and time again. The cases reported have none of the typical appearances of true smallpox. I am not alone in this statement. I regret that the time allowed me does not permit my enlarging on this point. Whenever this disease has appeared there has been this same difference of opinion as to its identity with variola vera. The older practitioners, as a rule, who treated smallpox twenty years ago, constitute a majority of the doubters. The text-books written from twenty to fifty years ago do not describe any epidemic of smallpox where, as a rule, there was no secondary fever, no pustular stage, no pitting and no mortality. Some of our more recent works on practice have been rewritten on the subject of variola vera and have been made to conform to many of the features of this disease.

One of the most nonsensical arguments, or rather, statements, made in regard to this present epidemic is that continued vaccination through several generations has so modified the systemic conditions of the people that this epidemic in its mild form is easily accounted for. This statement is completely negatived by the fact that there has been no systematic vaccination of the negro population since 1860, and but little up to that time, as the Southern planter depended on isolation to protect his slaves, and not on vaccination. In the South the negro has borne the burden of this epidemic, representing fully 75 per cent. of the reported cases. In Tennessee vaccination, outside of the cities and incorporated towns, has been almost entirely neglected since the war of the sixties, owing to the reports of suffering brought back by returning soldiers who had been vaccinated.

Now, in conclusion, permit me to repeat and emphasize the fact that there is no stronger advocate of repeated vaccinations in this Association and no greater believer in its efficacy and protecting influence against variola than I am, but the point that I make in this discussion is that vaccination has not protected against this disease, as has been proved in the cases reported by me and in the letters received from different sections of our country, which I herewith submit and make a part of this paper.

In addition to what has been already said, I desire to present a few communications in regard to this disease that I have received from different parts of the South when the cases first appeared. I desire to show that I am not alone in the views presented in my paper. The first is an extract from an article by Dr. J. P. Fletcher, of Lonoke, Ark., sent me when I first began the preparation of my paper:

> Much discussion has been had at the bedside of the patient, as well as at the offices of the physicians of our town and surrounding country, about an eruptive disease which has been lingering in our midst since August 17 last. The history is as follows: About August 1 last, one of our citizens visited Little Rock, Ark., and was detained over night, which he spent at a private boarding-house. Upon returning home he was taken with a chill on the morning of August 17, which was followed with a high fever, pain in the head and back, lasting thirty-six to forty-eight hours, when a full crop of papules made their appearance on the face, followed by a full crop on the body. The fever subsided with appearance of

eruption. Patient up in five or six days. No secondary or recurrent fever followed. Desquamation leaves a discoloring of the skin, but no pits, but rather a prominence. This gentleman's family consists of wife and three little boys from 5 to 9 years of age. The boys took it in the course of the following twenty days. The wife and mother escaped entirely. The attending physician diagnosed the case chicken-pox, confirmed by the president of the State Board of Health. . . . I will now give you a brief history of the most interesting and mystifying case that has come under my care. Dr. J. F. O., who was well vaccinated two years ago, was taken ill December 14 or 15, with all the symptoms of all the other patients. There was a full crop of eruption, representing all the stages of full pustule—umbilication excepted—to the minute papule, winding up without a single pit. Up to the 12th inst. his face was still covered with papules, which were gradually fading, leaving the surface smooth and natural. His family consists of father, mother, wife and two little girls. The elder of the little girls was vaccinated when her father was, some two years ago. Both children and grandmother had mild attacks. Grandfather and wife escaped entirely. What is this disease? From the teaching of our latest and best writers I can not think it smallpox. I have been exposed to it from the commencement, and am not an immune from smallpox. Up to this writing have not had any symptom of the disease. I have treated thirty-two cases. We have had, in all, possibly sixty cases in town, with only one death.

Lonoke, Ark., Nov. 29, 1899.

Dear Doctor:—With great pleasure I have watched the proceedings of the Tri-Medical Association during its late session. I was very much interested in your paper on smallpox diversion. The *Commercial-Reporter* gave only a synopsis of your paper, but sufficient for me to comprehend your position in the matter of the disease. In August, 1898, the first case occurred in our town and during the summer and fall we had from 50 to 75 cases, in which we had but one death, and that was a young lady of very delicate constitution, who was also suffering from menstrual trouble. We were informed by an expert, so-called, that as soon as cold weather set in the disease would spread rapidly and be attended with great fatality. During the cold weather, however, there were but few cases, and these very mild, so much so that few called a physician or even consulted one. Up to May 1 of the present year we had 150 cases in the town and surrounding country, with but the single death mentioned above. Another remarkable feature of the disease was that the only fully confluent cases which came *under my care were those that had been vaccinated a year or* two before. Again, in families of from 5 to 8, 2 to 6 cases would occur, and the rest escape. There was no odor nor recurrence nor secondary fever or pitting after desquamation. My experience with this disease, so-called smallpox, is that it is evidently not even moderated by vaccination, but rather intensified. It is still lingering in our state and it seems to be a concurrent opinion with the profession that it is smallpox, except a few independent thinkers who have the backbone to express their convictions to the contrary. I hope some learned expert will soon find a name for the intruder.

Yours fraternally, J. P. Fletcher, M.D.

South Boston, Va., Dec. 1, 1899.

Dear Doctor:—I am heartily in favor of abandoning the old name of smallpox as applied to this mild or pseudotype of the disease. We have had some 75 or 100 cases here, and they all seemed to get along all right without even the attention of a physician; some kept at their ordinary duties until detected by the health officer. Not one case was sick enough to require special attention. Many of them were negroes, and, according to our best writers, this race usually suffers most. In this instance the negroes suffered least; many of them never stopped from their usual labors. I am unable to understand why we should have such a mild type of so fatal a disease. Vaccination seems to have but little effect in preventing or modifying the attacks. Hence I am at a total loss to know what to call the disease that is contracted from those who have previously undergone thorough vaccination. There does not seem to be any difference in severity in those who have and those who have not been vaccinated. Do you think genuine smallpox can be contracted from varioloid? Fraternally,

Bittle C. Keister, M.D.

Columbia, Tenn., March 15, 1900.

Dear Dr. Happel:—It is currently reported here that you have backed down from the position you took last year in regard to this thing that every little four-by-six doctor is calling smallpox. We have it here, and have hundreds of cases, and not a single scar or death from it yet, nor a single case that has been sick enough to give any concern; any number of them running their course in four to seven days and none lasting longer than fourteen days; never any true pustules or crusts nor any secondary rise of temperature. It occurs as readily and as often in persons recently vaccinated as those not. Vaccination takes as readily after the attack as in those who have not had it.

It occurs as severely in those that have previously had true smallpox as in any other class, as I have had an opportunity to observe in two cases. The patients are sick only one or two days and often not then. In other words, it has nothing in common with true smallpox, and I am very sure it is nothing akin to the genuine article. Please write me if you have changed base in the matter. Your sincere friend,

W. K. Sheddon, M.D.

Coldwater, Miss., Jan. 11, 1900.

Dear Doctor:—This is to obtain a knowledge of your views relative to a very prevalent skin disease simulating smallpox that is scattering all over several states in the South. We have it in this town and prominent physicians are very much divided in opinion as to what it is. It is unnecessary to give you symptoms in detail, as I learn that you have the same trouble in your county. But very few of my cases pit, and none seem to be protected by vaccination. The mortality is very low. I am not of the opinion that it is true smallpox. But many of my older colleagues are very friendly toward the variola idea, yet none have ever seen a case of smallpox before the appearance of this disease. If you have named the trouble please write me full particulars. Yours truly,

Geo. H. McCain, M.D.

McKenzie, Tenn., March 24, 1900.

Dear Sir:—Our town is just now having its first experience with the so-called smallpox, so pronounced by Dr. Albright, Secretary of the State Board of Health. Dr. R. D. Given, one of our oldest and ablest physicians, stoutly contends that it can not be smallpox. He has been attending the patients daily and has treated old-fashioned smallpox several times during his practice. It has been told here that you contended for a long time that the disease that has been *called* smallpox by the state health authorities in your county was not smallpox, but that you had recently changed your views and are now convinced that you were mistaken in the opinion you formerly held. For my own satisfaction, and for that of others, I would like to know if this is true. Very respectfully,

J. T. Burns.

Hickman, Ky., May 13, 1900.

Dear Doctor:—Have you had any experience with the cutaneous eruption that has infested this country for the past twelve months or more? If so, do you think it is smallpox as it has appeared in this country before, or as it is described by the authors on the subject? Do you think it likely we could have at this place over a hundred cases of smallpox—most of them negroes—broken out from head to foot—many of the lumps so close together as to compress each other like peas in a pod and not have a case of secondary fever? A few of the cases had chills; most of them had chilly sensations, headache, backache and fever. Eruption appeared on third day. Patients feel ill on the fourth day; some of them on the fifth. After that the appetite is good. They claim to feel as well as *ever, and go to work if you allow them. The eruption remains* out for weeks in some cases. There is a little milky fluid under the cuticle about the fifth or sixth day. If the cuticle be rubbed off, the lump is smooth and oval, and is removed by absorption at the base, remaining oval on the apex—unless scratched or irritated—until it disappears, leaving no pit whatever. Some of these cases have quite sore throats for two or three days. One of my cases had marked photophobia, with inflamed lids. In all the cases—I have seen over thirty—I have prescribed a gargle in four only, and solution of boracic acid for the eyes in one. That is all the medication they received, except cosmolin over the exposed parts. If we admit this to be a mild type of smallpox, do you think it would have been advisable to have placed all these cases in a small pest-house? Might it not have aggravated the type? I had guards put at the houses, and isolated them the best I could in that way. But after the fifth day it was almost impossible to keep them confined in any place. Yours, etc.,

Alex. A. Faris,

Crockett Mills, Tenn., May 26, 1900.

Dear Doctor:—I am desirous of obtaining your ideas on an "eruptive disease" which we are having at present in this part of Crockett County. I have been informed that you have had considerable to do with a malady of this type in your county, hence my writing you. I will relate the history of a typical case which, with two others not so typical, has been under my care and observation. The patient, male, white, aged 17, was taken sick the 10th inst. with slight fever, headache, malaise, etc., as the history was given me on Saturday, the 12th, which was the first time I saw him. At this time, the third day of his illness, he complained of frontal headache, general malaise, constipation and some muscular pains; his temperature was 101.2 F. No chill had preceded these symptoms, nor was there any nausea or vomiting or lumbar pains. There had been also in the same family, about two weeks previous to the case in question, some eruptive trouble, which I did not see, but which was diagnosed by the attending physician as "biliousness and impetigo contagiosa." This patient, a girl, remained in bed only two days, so I was informed. Knowing that there had been a "suspicious case" in the family before the boy was taken sick, I took particular care to examine his entire body for some sign of an eruptive trouble, but found none. I inferred therefore that the case was one of la grippe. On the following morning I called again, at which time the boy was covered from "head to foot" with a vesicular eruption, each having a "halo." His temperature at the time was normal, all discomfort had disappeared, and, to use the boy's words, "he felt like being out." These vesicles were on all parts of the body, but more particularly on the face and hands, and not more than one in a hundred were umbilicated, and then only slightly so. On pricking them with a needle they at first would collapse, but later would not, showing that they were reticulated. They remained in the vesicular stage for four days, when they assumed the pustular form, going on to scab and desiccation during the next twelve days. As before stated, there was no pre-eruptive rash of any description, neither was there even a papular stage preceding the vesicular, and his temperature stayed at normal from the appearance of the eruption till the end of the attack. Three representative physicians of this county saw the case with me during the lactescent stage of the eruption, and they unhesitatingly diagnosed the case as one of true, discrete variola. From this diagnosis I dissented, for the reason that there was not and had not been anything charactristic of this malady any of the time, except the vesicular eruption, which was then present; and because the temperature, as in the other case, was normal, and remained so all the balance of the time. Neither was the beginning of the attack characteristic of variola—no chill or chilliness, no nausea, no "backache," and above all, no pre-eruptive rash, followed by papules, giving the "shotty feel" on palpation. In fact, there was absolutely no indication of an eruption until the crop of vesicles appeared. You will notice, too, that from the initial stages until desiccation was nearly complete only sixteen days elapsed, and there was no "secondary fever." I am sure the case was not varicella, because the eruption came too late for that, came out suddenly, and there was not the characteristic phenomena of papules, vesicles and crusts appearing on the same parts of the body in proximity. I omitted to say that the eruption appeared scantily on the tongue and the pharynx.

There have been more than fifty cases of this trouble in Crockett County, with no deaths, and in many instances the parties having the disease did not go to bed, or only stayed there two or three days. I can hardly bring myself to believe this to be variola; if so, I have been misled by the most eminent authorities, viz., Osler, Anders, Tyson and the American Text-book (Pepper). Now, Doctor, I have written you with no other motive in view than obtaining information, or rather obtaining your ideas on the subject, which I may say without any degree of flattery, I am sure are as good as I can obtain, believing, as I have a right to do, that you have seen similar cases and are competent to give me something definite on the subject. I shall hold what you say "sacredly confidential" if you desire it. The cases in question were never vaccinated.

W. T. Redmond, M.D.

Salt Lake City, May 23, 1900.

Dear Doctor:—I see by the program of the American Medical Association that you are to read a paper on "Pseudo (?) or Modified (?) Smallpox." This subject intensely interests me, as we are having an epidemic of modified (?) smallpox (?) in the West—Utah, Montana, Colorado, Oregon and Wyoming. The profession is at sea and many good men differ as to a diagnosis. Yours, H. N. Nayor, M.D.

PSEUDO, MODIFIED, OR TRUE SMALLPOX—WHICH IS IT?

H. M. BRACKEN, M.D.
MINNEAPOLIS, MINN.

The first term is in common use at the present time. Let us analyze it. It is applied indiscriminately to a mild eruptive disease prevailing quite generally throughout the southern and middle states and, to a limited extent in other parts of the country. This disease is admittedly like smallppox in many of its characteristics, but those who use the above term in describing it insist that certain characteristics of smallpox are absent. I presume no one will dispute the fact that the disease prevailing so generally, whether accompanied by slight or severe symptoms, is one and the same when the line of infection is clearly continuous. It is therefore all smallpox or not smallpox. Let us consider carefully some of the arguments used against the diagnosis of this epidemic disease as true smallpox.

First, the mildness of the disease! It is absurd in this day of advanced knowledge to put forward such an argument. We all know that there may be mild epidemics of diphtheria, in which the majority of cases may show but little membrane; that often diphtheria prevails as an epidemic under the false name of tonsillitis until a few deaths arouse the lethargic physician, or a microscopic examination reveals the presence of the bacillus of diphtheria. Who would say that an epidemic sore throat with the specific bacillus of diphtheria present was not diphtheria because the disease was of a mild type, and had none of the dangerous symptoms of malignant diphtheria? Again, we have probably all seen an epidemic disease with many of the characteristics of scarlet fever but varying in degrees of intensity from the mildest rash, characterized by the old-woman doctors of both sexes as scarlet rash, to the severest type with the accompanying fatal sequelæ. Would any intelligent physician of modern days say that the cases with the mild symptoms and those of the severe type were not one and the same? It was not many years since it was considered necessary to have the typical history of typhoid fever before we were willing to call a fever by this name, but now we know that there may be a mild typhoid fever with very few of the classic symptoms of that disease. Let us be reasonable then and admit that while it is the rule to have a mortality of from 25 to 50 per cent. with smallpox, it may be possible to have the disease in mild form with a very low mortality.

The eruption is said not to conform to the book description of smallpox. Are we such slaves to books that we can not make a diagnosis of smallpox without all the cases having an ideally-formed eruption? It is no uncommon thing to find grouped together cases with the typical eruption at one extreme and the non-eruptive cases at the other, with all grades of eruptions between. Would any one with the history of a common infection say that some of these cases were smallpox, and the others not? What would those who need a classical eruption in order to make a diagnosis do with the most fatal of all, the hemorrhagic cases? I presume they would call them purpura hemorrhagica instead of hemorrhagic smallpox.

The temperature is said to be too mild in the majority of cases. Why should not the temperature be mild if the infection is mild? It certainly would be a freak of nature to cause a prevailing fever out of all proportion to the degree of infection. The secondary fever is said to be absent. The physician who has to wait for the secondary fever of smallpox before he can make a diagnosis would do well to change his profession. Why should there be marked secondary fever when the eruption is mild? Not long ago I saw a young lady with probably not more than a dozen smallpox pustules on the entire body. Why should she have secondary fever? Her brother, a young man, contracted the disease from her. He had confluent smallpox and a secondary fever.

Those who wish to call this mild type of smallpox by some other name, point to the fact that good authors state the danger of infection from smallpox is present during the entire progress of the disease, and likewise that all who are exposed to a given case at a given time do not promptly succumb at one and the same date, about fourteen days from the time of exposure. But why should they? All individuals may not be equally exposed at one time. Some may be more susceptible to infection than others. It is possible for an individual to have absolute resistance to infection at one time and not at another. It is even possible to have a natural immunity against this disease, the same as with other infectious diseases. Some writers at least who use the evidence of mild or irregular infection as an argument against smallpox, in speaking of this disease seem to recognize the fact that as a rule it attacks all, or at least many, of the non-immune members of a household when it once appears. Those physicians who consider the disease smallpox are cognizant of the fact that all who are subjected to a casual exposure do not of necessity become ill. Why should they? With the disease in mild form it is quite natural that the degree of infection should be mild. But even with the disease in severe form a casual exposure is not necessarily followed by infection. About one year ago I visited a child who died of confluent smallpox while I was at the house. Her father, a physician, had failed to recognize the disease. As a consequence the whole village had practically been exposed, many of the inhabitants more than once, for the child lay ill in a semipublic room and had many visitors. Yet, following this there were only eight cases from direct infection.

It is said that some of the prodromal symptoms of true smallpox are wanting in this epidemic. Granting this to be so, it proves nothing. We do not need all of the classical symptoms of typhoid fever in order to make a diagnosis. If a few typical ones are present, that is sufficient. I venture to say that with the exception of the smallpox cases without eruption, all of those occurring even in mild form have a sufficient number of symptoms at some stage of the disease to enable the careful observer to recognize the presence of smallpox.

Some of the doubters state that vaccination does not protect against the prevailing epidemic. This does not agree with my experience. An old vaccination, an imperfect vaccination, a vaccination made after exposure, may not afford protection. But in a large percentage of *successful,* recent vaccinations protection is complete. Some have been vaccinating these cases during or immediately following their recovery with the belief that evidence of a successful vaccination under such conditions would tend to stamp the disease as not smallpox. Such a test is absolutely useless. There is no reason why vaccinia and variola should not exist at one and the same time in an individual. They may have some influence on each other without complete antagonism. It would be strange, however, if all those who had this mild form of smallpox should respond to vaccination made a sufficiently long time after recovery from the first disease. I do not think they all will, and my opinion in this matter has been borne out by the experience of those observers with whom I have been associated.

Regarding the advisability of calling this mild type of smallpox—for such it undoubtedly is—a modified smallpox there is little to say. It certainly is not varioloid, for by this we mean smallpox modified by vaccination, and many of these mild cases under consideration have never been vaccinated. If vaccination had been practiced quite generally over our entire country thirty and forty years ago, and then neglected during the past twenty years we might then think that a partial immunity had been secured. I do not lean to this latter belief, but rather to the opinion that we have nothing more or less than a mild type of disease, such as may occur at times with other infectious diseases. A few illustrations may be of value.

About a year ago I was called to see a man, aged 40 years, suffering from an eruptive disease called chicken-pox by his attending physician. He gave the history of having had somewhat marked symptoms before the eruption appeared, with but little discomfort afterward. The case had not been quarantined before the seventh or eighth day of the disease. The population of the village was about eleven hundred. Investigation brought out the fact that in all there were eleven cases in this village; nine preceding and one following this man. Most of these were adults, all closely associated. None had as marked eruption as the man under consideration. All had marked prodromal symptoms but not all of those described in books as belonging to smallpox. The source of infection for these cases was traceable to undoubted smallpox. The man under consideration had smallpox. The others had beyond a doubt the same disease, although in very mild form. None of the cases were fatal.

Again, in the early spring of 1899, a man, aged probably 50 years, returned from California, visiting for a time in Nebraska before reaching his home in southern Minnesota. At the time of reaching home he had a mild eruption, which did not discommode him at all, and which he called chicken-pox. Shortly after his return, his wife became ill with smallpox and died. She undoubtedly contracted the disease from her husband, who had had smallpox in mild form instead of chicken-pox. There were five other cases of smallpox from these exposures, varying in degree from a very mild exanthem to a most marked eruption. One of the patients, a physician, died of smallpox contracted while attending the first fatal case.

Again, early in August of 1899, it was reported to me that two young men, doing business in a city having a population of about 3000 inhabitants, were ill with chicken-pox. I advised the local health officer to be on his guard, as in all probability the young men had smallpox in mild form. Later I learned that no heed had been given my advice. The young men had carried on their business as grocers, regardless of the disease. From this infection there were in this city and vicinity over two hundred cases of smallpox *without a death.* However, there were four deaths in places somewhat remote, traceable to infection at this place.

It is not difficult to furnish illustrations like the above. There have been over one thousand cases of smallpox in Minnesota since January of 1899, having the characteristics of the so-called pseudo or modified smallpox. There has been a total mortality of a trifle over 2 per cent., although in some localities with many cases there have been no deaths. Some of the fatal cases were of the acute hemorrhagic type, causing death before the fifth day. In several of these cases a correct diagnosis was not made until after death.

We can not be too careful in dealing with the present general epidemic of smallpox, and those physicians who have failed to make a correct diagnosis or who are seeking notoriety by suggesting a new name for an old disease can do much toward aiding in the suppression of the trouble by admitting their errors, or at least ceasing to preach false doctrines.

TYPHLITIS, PERITYPHLITIS AND APPENDICITIS IN INFANCY AND CHILDHOOD.

CAUSATION AND RELATIVE FREQUENCY*.

JOSEPH HENRY BYRNE, M.D.
Visiting surgeon, Metropolitan Hospital and Dispensary.
NEW YORK CITY.

The title of my paper might possibly lead some to suppose that I was about to bring forward few or many well-grounded facts which might tend to sustain the theory of the older writers. I wish, however, to correct any such impression at the start, for I fear it is not within my power to add much, if anything, to a subject that has been so thoroughly gone over by the most competent men in the profession, both here and abroad. The wonderful strides that have been made in pathology and bacteriology, within the past two decades have so thoroughly revolutionized matters that we are forced to disregard theories that only a few years since appeared tenable, as patient research and the aid of the microscope have removed many an obscurity. However, this does not seem to have been the case with typhlitis and perityphlitis, as the theories that were first accepted seem to have been the result of mere speculation. Most of us are familiar with the teaching of Albers, which he advanced about 1838, and which was accepted as the correct view by the majority of all writers of text-books for nearly half a century. About the same time Grissolle did his best to controvert these teachings, as he certainly perceived that they were groundless. He was by many of his confrères looked upon as a "crank," and, in reality, he was the one who set the wheel of knowledge revolving in the proper direction. He rightly asserted that inflammations involving the cecum were not accompanied by accumulations of pus and perforation of the appendix, which we find in the right iliac fossa, when even dysentery and ulceration of this part did not tend to involve the adjacent connective tissue. He again claimed that disease of the vermiform appendix, with its phlegmonous inflammation, pus formations and perforations, explained in a satisfactory manner the chain of events as they actually take place, and he thus gave us a fairly true picture of what we now know positively occurs. His theory was not speculative, but was the result of patient and careful research and actual post-mortem investigations.

The weight of evidence is so abundant that we must be led to the belief that the premises on which the other writers based their conclusions, with the exception of Grissolle, were erroneous. We are also forced to the conviction that the inflammations around the cecum take little or no part in the production of appendicitis; also that few cases of typhilitis exist as a primary disease, and that perityphlitis only takes place as a secondary complication. In fifteen years I have never seen a case of primary typhlitis or perityphlitis, and the literature of recent years shows that the majority of others have had like results.

Hawkins, in his book on diseases of the vermiform appendix, while referring to the inflammatory trouble found in the right iliac fossa, states that the cecal theory has undergone gradual modification until it is now quite extinct, owing to the fact that all evidence is opposed to this theory, both clinically and pathologically. It is very easy to understand how such men as Laennec, Ferrall, Burne, Albers and others entirely ignored this little rudimentary offshoot when the great surgeon, Dupuytren, looked on the cecum as being the starting-point in the trouble, and it was probably owing to his support that the true cause of the disease was so long withheld from view.

Einhorn, of Germany, in 100 cases, found the appendix the origin in 91 per cent.; the cecum in only 9 per cent. Wallis, in 52 cases, found the cecum to be the cause of 10 per cent.; the appendix in 89.8 per cent. Renvers, in 586 autopsies after perityphlitis, found the appendix ruptured in 497 cases, and expressed as his view that five-sixths of all the fatal ones were caused by perforation of the appendix, and that perforation of the cecum occurred in 13 per cent. Agar, in 218 autopsies for a similar condition, found cecal perforation in but 29 cases. Volkmann stated that it was his belief that typhlitis and perityphlitis are due to perforation of the appendix, except in those cases of tubercular and typhoid ulceration of the cecum itself. Talamon says that early operation seldom, or never, shows the presence of inflammation or perforation of the cecum, and that we are, therefore, correct in ignoring the observations of the older writers. He, however, admits that it is secondary to the inflammation of the appendix; that the process takes place from without inward, owing to the proximity of the organ to the peritoneum covering the former. Hawkins, like Volkmann, believes that the cecum may be the seat of trouble in tuberculosis, dysentery and typhoid fever, but concludes that the process is then only part of the original disease, and that perforation under these conditions is not likely to occur. Stercoral accumulations in the cecum may very rarely produce a mild inflammation, but never give rise to ulceration and easily disappear on the administration of purgatives. Mynter, like all recent writers, states that the chain of events points directly to the appendix as being the primary seat of the trouble, and directs our attention to the predisposition of the affection to occur after one attack, whether that be mild or severe, and such, I firmly believe, must be the experience and conclusion of all of us.

Owing to the fact that the mucous membrane of the appendix is continuous with that lining the cecum, it would be a most natural assumption that inflammatory and ulcerative conditions involving the membranous covering of the latter would by extension spread to that of the former, but such does not seem to be its tendency.

The inner coat of the gastrointestinal tract is frequently the seat of varying degrees of inflammation during the periods of infancy and childhood, and we are all familiar with the different forms of gastro-enteritis and ileocolitis of the catarrhal, follicular and ulcerative types. If these ordinary inflammatory states played a major part in the production of appendicitis, we would frequently meet with this condition during early life, while statistics prove beyond question that the disease is rather infrequent before the fourth year, increasing between that period and the tenth, while the majority of cases take place between the tenth and thirtieth years.

---

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

If any relation existed between these two conditions, we would naturally look for an increase in the number of cases during warm weather, when the above diseases are more prevalent; but there seems to be no difference whatever so far as the seasons are concerned, as appendicitis is just as frequent in the cold as in the warm months. It is a well-known fact that inflammations in the large and small bowel have little or no tendency to involve the peritoneum, and that the opposite is the rule with an inflamed appendix. With this in mind it is easy to understand how the inflammatory process can extend to the serous coat of the neighboring parts and the adjacent connective tissue.

ANATOMY.

Before proceeding further it might be well for us to view the component parts of the appendix with its blood-supply and mesentery anatomically, for in these parts, as we will later see, are to be found a few potent factors in the causation of the disease.

From within outward we find the mucous coat lined with cylindrical epithelium with its basement membrane, tubular glands and closed follicles. The reflection or folding of this membrane, when such takes place, at the cecal opening, forms what is known as the valve of Gerlach. The submucosa is made up of connective tissue, with spaces for the blood-vessels and lymphatic openings. The muscular coat is composed of a few non-striated, longitudinal muscular fibers, with a varying amount of fibrous tissue, innermost to which are found some circular fibers that are not very numerous in the majority of cases, the combination of both forming the greater part of the entire wall of this organ. Some have gone so far as to state that no circular muscle fibers exist, but the majority rightfully claim otherwise, as the microscope has disclosed their presence on numerous occasions. The conformation of the fecal concretions so frequently found adds another proof of their presence, as the tapered ends and convex surfaces of these masses tend to show that peristaltic waves take place from either end of the appendix toward the center of these bodies.

Lastly, we come upon the serous coat, which, in the majority of cases, i. e., over 75 per cent., entirely surrounds this organ. While this membrane is in close proximity to the underlying structures of the appendix, and takes a more or less active part in all the inflammations involving it, it must not be forgotten that it is a distinct structure in itself, and is only a part of the general peritoneum.

The meso-appendix, which is triangular in shape, varies in size, sometimes accompanying the organ for its entire length; in other cases, and, in fact, in far the greater number of cases, it only extends part way; or, again, it is occasionally conspicuous by its absence.

The arterial supply, which consists of a single branch, passes along the free edge of the meso-appendix to the distal end of the organ; when no mesentery exists it passes beneath the peritoneum in the same direction. In the female an anastomotic loop is given off from the region of the right ovary.

The appendix varies more in size, position and general make-up than all the other structures of the human anatomy. The size seems to bear no relation whatever to the frequency of the disease, as a very large appendix is just as apt to become the seat of an inflammatory process as a smaller one. In childhood the organ is very rich in lymphoid tissue, has been compared to the tonsil, and, therefore, has been styled the tonsil of the intestines.

The appendix is an atrophied organ, or the rudimentary remnant of a lengthened cecum seen in nearly all mammalia except man. It is also found in the wombat, and is present in the different types of the higher apes, but in the latter, so far as our knowledge goes, it does not seem to become the seat of inflammation. It being an admitted fact that this organ is an atrophied, a functionless and rudimentary one, with a blood-supply that can easily be interfered with, and which at its best seems barely sufficient under healthy conditions, it must, therefore, be more or less susceptible to any inflammatory state. The physiologist up to the present time has not credited this little mischief-maker with any special function or assigned to it even a remotely-indirect part in our vital economy. Some have suggested that the secretion might act as a lubricant to the adjacent parts; but if such were really its office, the dwarfed condition which we find would not be the rule, but the exception. The fanciful ideas of some need not receive our consideration, as up to the present we know nothing of its good qualities, and have prudently learned to fear it. It, therefore, resolves itself into a useless and dangerous organ, and we may honestly classify appendicitis as one of the later additions to the ills that we are told man became heir to on the fall of Adam.

The first anatomic description of the appendix is credited to Capri, 1524. Videus, in 1561, applied to it the qualifying term "vermiform," which it holds to the present day, while the valve and the appendix were both described by Lieberkühn in 1739, but real accurate accounts did not appear until the present century. As early as 1759 a case of perforative appendicitis was described by Mestivier, and between 1827 and 1868 a number were recorded by English, French and a few by German writers. In these early cases, although the description points conclusively to the existence of true appendicular inflammation, all of them being of the perforative or suppurative varieties, the pathological conditions were not understood, and their views, necessarily, are not in accord with the knowledge which we possess at the present time. This offshoot from our alimentary canal can be looked on as unimportant, so far as its usefulness is concerned, but most important from a medical and surgical standpoint, owing to the fact that it is commonly the seat of pathologic changes. It did not attract much attention until within the past fifteen years, when the real importance of appendicitis became understood, its pathology disclosed and the different stages first described. Although the earlier writings of our foreign brethren first brought the subject to our notice, the credit for our present knowledge regarding the disease belongs to us, owing to the able contributions of Weir and McBurney, of New York, and Fitz, of Boston, which placed the disease within the proper focus, thus enabling us to intelligently understand the part the appendix played in the different conditions, as formerly described and as we see them today, our eyes being opened for the first time to a clearer insight into the sequence of events as they take place pathologically in this appendage. If I were to stop here I would be doing an injustice to one of the younger men in the profession, as it was Dr. Hodenpyl, of New York City, who first suggested that the bacillus coli communis played an important part in the production of appendicitis, and later observation by himself and others proved this to be correct.

ETIOLOGY.

Formerly the principal cause in the pro
disease was attributed to the presence

foreign bodies in the lumen of the appendix, and an operation that did not reveal the presence of such a body was not looked on favorably by the laity, so forcibly was this impressed on their minds. Within the past ten years or less the disease of this organ has attracted so much attention that its true character has been better understood, so that the existence or absence of orange, grape or date seeds, etc., is looked upon as playing but a minor part in the production of this affection. When, however, they do exist, they, like fecal concretions, act in a mechanical way, and thus become pathologic factors in bringing about the trouble, either by occluding the lumen, by interference with the blood-supply or the normal peristaltic movement, or, finally, by acting as irritants. The knowledge within our possession leads us to classify our causes under two main heads—predisposing and exciting.

PREDISPOSING CAUSES.

The variations in the size, position, character of the lumen, and the anatomic structures in and about the appendix, call our attention immediately to the consideration of a few very important agents in bringing about this disease. The average size of the appendix, according to Ribbert, varies during the different periods, being longest during early adult life. At birth it measures 2 4/7 cm.; up to 5 years, 7 2/3 cm.; from 5 to 10 years, 9 cm.; from 10 to 20 years, 9.75 cm., and from here on it seems to decrease. With the length it may be well to take into consideration the mesenteric attachment. When the latter accompanies the organ in its entirety, or nearly so, it is apt to assume a position that is straight, or one that is nearly so; but where the mesentery is incomplete it may then become curved upon itself or twisted, which it actually does, thus interfering with the circulation and the free drainage of the normal secretion, which, when locked up for any length of time, may of itself, or by the addition of another factor, bring about a catarrhal condition. Again, the curve, or kink, would naturally retard the egress of any fecal material that might perchance gain admittance, and we then have added a new element of danger, as the conditions are then ripe for the formation of a concretion which may receive further additions of fecal material, and which may also become the seat of calcareous deposits.

The next point for consideration is that of position, and we are all well aware that the appendix is not exclusive in its choice. It, however, in about 60 per cent. of the cases, selects one of two positions; in the first the appendix takes an upward and inward direction, looking toward the spleen, and in the second instance it lies directly behind the cecum itself. Both these favor the complete emptying of the cavity of its normal secretion or any fecal matter that might possibly have gained admittance. If, on the other hand, the selection is in any way opposed to gravity, we have certain elements of danger added, as the ingress of material is facilitated and the egress is more or less hampered; thus an unusual amount of labor is put on the muscular coat, which we all must acknowledge is barely sufficient under normal conditions.

The appendiculo-cecal opening and the cavity itself are of some moment, and, therefore, must claim a share of our attention. The former being the common entrance for both incoming and outgoing material, an opening that would permit free passage is one that we would naturally select, and in the majority of cases this is not always what we find, as the door of communication is sometimes so narrow that a filiform bougie is passed with difficulty. Whether this state is congenital or more likely the result of one or more mild attacks of inflammation, or retrograde changes, does not concern us only so far as it obstructs the way. Along the canal itself constrictions are commonly met with, and act in a similar manner to the above. They are the result of cicatricial contractions following one or more inflammatory attacks, and vary according to the degree of destruction of the mucous membrane and the underlying tissues. The lumen varies considerably, a narrow pouch facilitating the complete discharge of mucus or fecal material, when no strictures or twists are present, while a large one adds to muscular effort, and, owing to the likelihood of its incomplete emptying, favors the production of fecal concentrations and inflammatory processes.

A very interesting table is one given by Ribbert, in which he tells us he found 99 cases of stricture in 400 bodies, and what is still more interesting, that the frequency varied with the age of the individual: At 1 to 10 years, in 4 per cent. of bodies; at 10 to 20 years, 11 per cent.; at 20 to 30 years, 17 per cent.; at 30 to 40 years, 25 per cent.; at 40 to 50 years, 27 per cent.; at 50 to 60 years, 36 per cent.; at 60 to 70 years, 53 per cent.; at 70 to 80 years 58 per cent.

The infrequency of stricture between the first and twentieth year leads to an important question: i. e., whether the lesions are the result of inflammation or retrograde changes. Fitz and others claim that the condition is pathologic, but Ribbert and Hodenpyl, while admitting the possibility of the former, state, however, that the majority are the natural consequence of the latter. Strictures have been found a number of times in the fetus, and Hodenpyl notes two cases found by him in the new-born.

Most of us are called on to treat children suffering apparently from some stomach or intestinal trouble, which usually responds to treatment in the course of three or four days, the cause being ascribed to some indiscretion in diet. It is my firm belief that if we were a little more careful in our examination we would often find the appendix the seat of a mild catarrhal inflammation, which later on may result in a constriction. As an exemplification of the effects of these mild attacks of inflammation, I will cite a very interesting case which lately came under my observation.

A little girl between 12 and 13 years old, according to her mother's statement, for several years had occasional attacks of what she called "biliousness"—two or three each year—during which time she suffered from nausea, vomiting, pain in the abdomen and headache. The child usually recovered in three or four days. A purgative was always administered with other home treatment, the doctor not always being consulted. The last seizure was more severe; about the fifth or sixth day the family physician was consulted, and the following day, through his kindness, I saw the patient. A few hours after my first visit I removed the appendix and found the proximal end of the canal nearly closed for about one-fourth of an inch; the minute communication that still existed was filled with broken-down material. The appendix was a little over three inches long, and three-fourths of an inch wide at its center. It was flattened upon itself, gangrenous, ruptured through both sides a little above the center, and still contained within its lumen a large fecal concretion. The cavity itself was considerably dilated, this being due to the long-continued retention of mucus and fecal matter. Firm adhesions walled in about two ounces of pus, detritus and feces. The stump was so rotten that it was sutured with difficulty, and finally gave way on the eighteenth day from incessant coughing, caused by a complicating double pneumonia. The patient eventually recovered.

The concretion in this case was evidently secondary to one or more attacks of catarrhal appendicitis, for had the opening been many times larger it could not have gained admission to the cavity. Healing by granulation near the opening resulted in the formation of cicatricial contractions, the fecal matter that entered was locked up within its walls, the watery constituents absorbed and the first stage of this condition was completed. The dilatation of the lumen followed from the retention of the normal, and, later, the exaggerated, secretion, the concretion acting as a ball valve at the door of communication. The subsequent attacks resulted from decomposition of mucus, the irritation caused by the presence of the concretion, interference with the circulation, and, lastly, from the invasion of micro-organisms.

Comparatively speaking, the appendix is relatively larger in fetal life, infancy and childhood than it is in adults; and, according to Ribbert, it compares with the large bowel as 1 to 10, while in adults its relation is 1 to 20. It is also somewhat longer and wider in the male than in the female, and this holds good in the early periods of life.

With the diminishing ratio, which is nothing more than a retrograde process, the vascularity of the part must also be lessened, and, as the tissues receive their nourishment through this channel, I am firmly convinced that the slight immunity that exists in the earlier periods of life can be credited to the fact that these changes in the majority of cases are not sufficient to interfere with the integrity of the organ until after the fifteenth year, and statistics support this assumption, as only about 15 per cent. of all cases of appendicitis occur prior to the fifteenth year.

Mucous Membrane.—In early life the mucous membrane of the appendix possesses wonderful power of absorption, and this in itself becomes an active predisposing cause.

Sex.—All statistics prove beyond doubt that the female is less frequently the victim of appendicitis than the male, and the percentage does not seem to vary any more in the earlier periods of life than it does in later years. Some good reason evidently gives the female this advantage, and this is accounted for by the increased blood-supply, a small anastomotic branch being given off from the region of the right ovary, and passing along the appendiculo-ovarian ligament of Clado, and secondarily to the comparatively smaller size of the organ itself. In the male a single blood-vessel supplies the part, and all anatomists agree that no anastomosis exists. When for any reason the circulation is interfered with by kinks, twists, constricting bands, compression, etc., compensation can not take place, and the result is a lowering of the vital powers, an inability to resist even a mild inflammation, if such should attack the part.

Recurrence.—Mucous membranes that have once been the seat of catarrhal inflammations are predisposed to successive attacks. This is seen in that covering the tonsils, bronchi, air-vesicles, bladder, etc., and the lining of the appendix does not seem to be an exception to this rule. The following figures, taken from the work of Mynter, treat particularly of relapse, and are worthy of note, as they give the result of accurate observation, but, unfortunately, do not state the actual number of cases on which the percentage was based: Irish found that 50 per cent. of the cases tabulated by him suffered recurrence; Price, likewise, 50 per cent.; Richardson, 49.4; Ransohoff, 50; Knaussold, 23; Krafft, 22; Porter, 9.5; Bryant, 11-17; Sahli, 20; Gage, 33.5. Some place the ratio much higher, others consider it less. Although these cases were taken collectively, and, therefore, do not refer specially to early life, they are yet important, owing to the fact that 15 per cent. of all cases occur between the first and fifteenth year. My own experience, however, leads me to believe that recurrences are less frequent in infancy and childhood than they are in later years, although the first involvement may lay the foundation for attacks which occur later. At all events, it is true that one attack predisposes to subsequent inflammation, whether this be occasioned by secondary constrictions of the caliber of the appendix or a contraction of the orifice itself, by adhesive bands, the presence of concretion, or any condition that will in any way interfere with the circulation, and, finally, by a resulting subacute inflammation that sooner or later becomes active. Occasionally we find a complete occlusion of the entire canal in the adult. While such is possible during early life, I have never seen a case recorded.

Constipation and Diarrhea.—Either of these alone probably plays little or no part in the production of appendicitis, but when associated with any of the above enumerated predisposing causes, the result may occasionally be an inflammation.

If the observations of Maicaigne be true, namely, that the bacillus coli communis found in diarrheal discharges is much more virulent than that found in the healthy bowel, diarrhea might then become a potent factor in the production of the disease.

Any inflammatory state of the membrane in this region may at times play a part in the causation of the disease, especially when the mucous coat at the door of communication is involved, as, owing to the devitalized condition of the structures, the epithelium lining with its basement membrane may undergo a destructive process, the repair of which results in the formation of cicatricial bands. These mild catarrhal inflammations may play a more important rôle in the etiology than we give them credit for, and the fact must not be lost sight of that the powers of absorption which the appendix possesses are greatly enhanced during early life on account of the abundance of lymphoid tissue: its power of resistance gradually diminishes as the retrograde metamorphoses advance—which retrogression may easily become pathological—and, therefore, when attacked, it must necessarily succumb to a gradual process of destruction on account of its lessened vitality, which destruction may be complete or otherwise.

Exposure.—Deaver notes three cases that are interesting: one caused by wet feet, a second due to a cold shower taken after a hot bath, and a third from being chilled shortly after taking a full meal. These are possibilities, but are so remote that few of us will ever be able to record such instances.

Typhoid and Tuberculosis.—Both are minor factors in the causation of the disease: the former more frequently than the latter, as the solitary glands are often the seat of ulceration, the healing process resulting in the formation of a stricture. Both are common occurrences post-mortem, but are seldom met with after operation for appendicitis.

Exciting Causes.—Micro-organisms are with[illegible] ht prime factors in the production of appen[illegible] may act independently, but the invasion is [illegible] ly secondary to a twist, kink, constriction, interference with circulation, the presence of a concretion or a foreign body or any irritating material, or condition that will bring about an action or virulent state of the bacillus coli communis, a natural inhabitant of the intestinal tract, which, under normal conditions, seems harmless. Welsh believes that the germ is innocent, so long as the integrity of the mucous membrane is maintained, but becomes pathogenic when the same is the seat of inflammation or of traumatism. Others disagree with this view, and Hodenpyl found numerous bacilli on the walls of the appendix without any lesion of the mucous membrane. This bacillus is without doubt a most important etiological factor in appendicitis, as Hodenpyl records its presence 34 out of 35 times; Hawkins, 57 times in 61 cases, and the experiences of many others have given like results.

Traumatism.—This occurs much less frequently than we are led to believe. It is of two kinds, direct and indirect; the former due to a pin or sharp foregn body that might enter the lumen of the appendix, causing an injury or abrasion of the mucous membrane, by penetrating a part of or the entire wall itself, while the latter is caused by violence directed through the abdominal wall. Instances of direct injury have often been recorded, and while it is possible for indirect violence to become an etiological factor, I feel positive that the appendix is already in a receptive state—from one or more of the predisposing causes mentioned—and, therefore, that the traumatism, while it may seem the active agent, is in all probability only a minor factor in the causation of appendicitis.

Foreign Bodies and Concretions.—Both, when they exist, can be credited with bringing about an inflammation. The former are introduced from without—seeds, gall-stones, pins, buttons, etc.—and may become a nucleus for the latter, which are always found in the appendix. Foreign bodies occur less frequently than is generally supposed and therefore do not play the important rôle with which they were formerly credited.

Concretions are of more frequent occurrence, and act first as irritants to the mucous membrane, producing catarrhal inflammation, facilitating the invasion by micro-organisms, and then by mechanical interference, either by occluding the lumen, acting as a ball valve at the opening itself or at the seat of a stricture, causing retention of secretion, with its consequent dilation and thinning of the walls of the organ, also by obstructing the circulation even so far as producing gangrene, and bringing about necrosis from pressure.

Actinomycosis.—Kelynack reports one case caused by this, Lange another; both, however, were in adults, and even here the instances are rare. The parasite has not been charged with producing appendicitis prior to the fifteenth year.

Although the case which I am about to relate does not come within the scope of my subject; it is a very interesting one and records the first attempt—successful or otherwise—to expel a fecal concretion by digital manipulation.

April 15 I was called to see a boy of 10 years, who for five or six days previous had suffered from constipation, nausea and general malaise. On the 13th, after an attempt to force a movement, he was taken with a slight pain about the region of the umbilicus, which continued at irregular intervals. The family noticed his condition, but did not attach any importance to it, and he was therefore permitted to take a horseback ride on the afternoon on the 14th. He returned in a short time, stating that the jolting increased his abdominal pain. After returning home he went to bed, and on the following morning visited Sunday-school, where he was seized with severe vomiting, the pain becoming so intense that he finally had an attack of syncope. I saw him a few hours later; he was on his side, with his thighs flexed, and stated that this was the most comfortable position; temperature was 101, pulse 114; he complained of continuous pain in the umbilical region, with rather frequent spasmodic seizures so severe as to cause him to cry out. The entire abdomen was found to be somewhat sensitive, but the tenderness was most marked in the right iliac fossa.

On careful digital examination the appendix was found in a perfect state of erection and in a somewhat unusual position, i. e., on the outer side of the gut, directed upward and outward toward the crest of the ilium. The abdominal wall was exceedingly thin, the muscles not very tense, and it was therefore exceptionally easy to make out the parts.

I judged that the appendix was about three inches in length, and about one inch from its distal end I discovered one small, but rather hard, concretion which I was able to dislodge and pressed toward the gut. A purgative was administered and an ice-bag applied.

April 16: Temperature, 101; pulse, 104; pain still present; tenderness in right iliac fossa more marked; appendix could be no longer made out distinctly. I suggested an operation, and while the father appreciated the condition, he preferred to wait till after my visit the following morning.

April 17: temperature, 99; pulse, 84; complained of no pain; tenderness still present, but greatly diminished. The appendix could be made out, but the concretion was no longer in evidence. The boy said he was perfectly well and complained of extreme hunger.

April 19 he was permitted to sit up, and passed out of my hands, as the parents considered a recurrence the main indication for an operation.

The expression of hardened fecal masses by digital manipulation, to my knowledge, has never before been referred to, and although the cases where this mode of procedure would be applicable must necessarily be few, yet I could not refrain from calling your attention to the manner in which this very satisfactory result was accomplished.

TRAUMATIC INSANITY.*

WITH REPORT OF A CASE.

E. G. CARPENTER, A.M., M.D.

Superintendent Columbus State Hospital; Professor of Nervous and Mental Diseases in Ohio Medical University; Neurologist to the Protestant Hospital.

COLUMBUS, OHIO.

The absence of sufficient clinical, pathologic and histologic data often give rise to mooted medical questions. Any evidence brought to view, having the semblance of fact, is grasped with avidity as an addition to the fabric of truth. As long as a medical question remains undefined, open to all contributors, so long is there an opportunity for error to hold sway, and thus lend perpetuity to its obscurity. The truth-seeker, therefore, must still busy himself in combating the false and vagarious, and not permit them to foist and fix themselves upon that which is in most need of truth and clearness.

In the light of to-day's science, moral causes figure more lightly in the etiology of insanity, and more stress is being laid on such physical causes as heredity, degeneracy, the diseases causing malnutrition, infectious diseases and autointoxication. Surgery has been strongly suggesting the participation of pelvic diseases, postoperative influences and traumatism as causal factors. In this eagerness to explain much of the obscurity in the cause of insanity, injuries to the cranium have been given some prominence. Believing it to be one of the rarer causes, I wish to offer the following report of a case, with some added observations:

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Case.—F. B., male, age 39, native of United States, single, musician; no family or personal history obtainable, except that patient habitually used alcohol to excess; not epileptic, sleep irregular, but general health and appetite good. Regarding his mental condition, the physician making out his commitment papers said of him: "No evidence of mentality since January 29, 1898. On that date he was struck by a motor car and sustained a fracture at the base of the skull."

The following statement was given by Dr. T. C. Hoover, visiting physician to St. Francis Hospital, where the patient was taken immediately after his injury:

The patient and his brother were street musicians and were struck by an electric car. As a result of the injuries received, the brother, who was blind, died, and our patient was an inmate of St. Francis Hospital from January 29 until March 14, when he was brought to the Columbus State Hospital. When received at St. Francis Hospital he was in an unconscious condition, and remained so for about a week. During this week he developed ecchymoses about the eyes. He had no hemorrhage from the ears, but presented in other ways signs of fracture at the base of the skull. As he gradually regained consciousness and was able to speak, he showed evidence of mental disturbance, which was characterized more by a condition of dementia than by any active mental symptoms. Before he left the hospital he expressed delusions, especially concerning his brother, whom he would not believe was dead. At the time of leaving the hospital he was able to be up and to walk about, and to perform some of the feats to which he had been accustomed on the streets. On March 14 his mental condition had not changed. He remained demented and held to his delusions, and in this condition he was sent to the Columbus State Hospital. Aside from the mental symptoms described, there had been no symptoms of cerebral or meningeal disease.

At the Columbus State Hospital: From the date of admission he was in fair physical condition, ate and slept well, and the functions of all his organs appeared to be physiologic, excepting that he complained of severe and almost constant frontal headache and pain in the right ear, which was quite deaf, but at no time was there any discharge from the ears. His mental condition changed very little, however. It was characterized by extreme loss of memory for both old and recent events, a lack of appreciation of his surroundings—in short, a case of advanced dementia. About the first of August these symptoms became more marked, and three weeks later he developed fever, went rapidly into a comatose condition, had frequent and prolonged attacks of convulsions in which all the extremities were involved, and died on August 28. His temperature during the last few days was in the vicinity of 103 F.

Autopsy twelve hours after death: Well-nourished male, apparently 35 years old, rigor mortis marked, no special marks on body. Internal organs in normal position, no exudates or other foreign substances in the various cavities.

Lungs: Both have old adhesions at apices and posteriorly, are edematous, especially in lower lobes; no consolidation.

Heart: Marked hypertrophy of left ventricle, valves throughout in good condition, muscle rather soft and shows streaks of fat, especially plain on the papillary muscles.

Spleen: Slightly enlarged, capsule thickened and opaque, pulp soft, rich in blood, with stroma well marked.

Kidneys: Capsule adherent, tearing off kidney substance on removal; substance markedly yellow, in spite of the abundance of blood it contains.

Ureters and bladder show no change.

Liver: Large; weight, 1600 gm.; very light in color and soft; fatty, rich in blood.

Gall-bladder: Normal size; contains a quantity of light-colored bile.

Gall-ducts: Pervious.

Stomach and intestines present no abnormal conditions, nor does the pancreas.

The aorta, both at the arch and in the descending portion, is rough, with elevated yellow patches and calcareous patches, especially in the ascending portion of the arch.

Brain: Skull-cap thin; longitudinal sinus contains fluid blood; dura thick, opaque; vessels distended. Two large dark-red patches over the parietofrontal region of the right side, caused by comparatively recent hemorrhage confined between the dura, and a thick well-organized exudate extending on the inner side of the dura over both hemispheres. Under the pia-arachnoid is a large amount of yellow pus, enveloping the entire brain, especially thick over the base, and extending the entire length of the cord. The vessels of the pia engorged. Weight of brain, 1500 gm. Ventricles filled with the same kind of pus as that under the pia. Bacteriologic cultures made from this pus gave a pure culture of a short, thick, straight bacillus, which is also seen in the stained sections of the brain and cord, lying in the pus that fills the subpial spaces and the central canal of the cord. A slight scratch on our pathologist's finger, unnoticed at the time of the autopsy, caused a severe infection, accompanied with high fever and rapid enlargement of the axillary glands. Microscopic sections of the cortex and of the cord showed the blood-vessels to be unusually numerous, prominent and distended with blood, and a diffuse infiltration of round cells with well-stained nuclei.

On stripping off the dura from the floor of the cranial cavity, an old fracture of the left side of the occipital bone was disclosed, which had been faultily repaired. At the left posterior quadrant of the foramen magnum a lens-shaped piece of bone, 5 cm. long by 2.2 cm. wide, and slightly elevated above the surrounding parts, was broken loose, having been attached anteriorly by the narrow strip of bone lying between the posterior condyloid foramen and the margin of the foramen magnum, and attached posteriorly for a distance of 2.5 cm. where the fracture had completely united, leaving a curved line 3 cm. in length between these two points, ununited and open. This line of fracture crossed at a very acute angle the inferior curved line of the occipital bone, and ended in the median line, one-third of the distance from the inferior curved line to the occipital protuberance. Here it met with another very distinct line of fracture, extending from the posterior median edge of the foramen magnum, backward and upward, a middl of the occipital bone almost to its upp wh it made an abrupt curve to the left across the parietal bone, becoming less distinct, and finally being lost near the posterior edge of the temporal bone. This line of fracture, 16 cm. long, was united except for a distance of 2 cm. at its lower extremity, where there was a wide gap, with thick, well-rounded edges, forming part of the plane side of the before-mentioned lens-shaped piece of bone broken from the surrounding part. The bone about these lines of fracture was intensely injected. The dura was thickened over these parts, but shows no scars, nor were the sinuses involved.

Further preparation of the base of the skull showed other fractures. The apex of the petrous portion of the right temporal bone was cut off 3 cm. from its tip by a line of fracture which ran on the anterior aspect from the foramen spinosum upward and outward, crossing the superior ridge just internal to the eminence for the superior semicircular canal, then downward on the posterior aspect to the outer extremity of the foramen lacerum posterius. The articulation behind with the basilar process of the occipital bone, as well as the articulation in front with the great wing of the sphenoid, were both distinctly separated, and show evidences of the absorption of bone. The articulation of the left petrous portion with the basilar process of the occipital was also somewhat loosened.

The pathological findings in this case, then are: An extensive fracture of the base of the skull, a traumatic pachymeningitis hemorrhagica interna, with recent hemorrhages into the organized membrane, and an acute purulent meningo-encephalitis, all these superimposed upon a chronic alcohol poisoning, as shown by the arterial changes and the fatty degeneration of heart, liver and kidneys. Our explanation of the fracture is this: Severe mechanical violence, applied to left side of the occiput directly, caused the fracture of the left occipital bone. The strong bridge formed by the petrous portions of the two temporals and the basilar process of the occipital wedged in between them transmitted the force of the blow to the right side of the skull, where it expended itself in loosening the articulations with the occipital bone and in producing the transverse fracture of the petrous portion of the right temporal bone at its point of least resistance, and at the same time damaging the structure of the internal ear on that side. The avenue of infection of the subsequent purulent encephalitis was undoubtedly this last fracture, as there was no focus of suppuration elsewhere in the body from which infection might secondarily have taken place.

The sudden onset of the acute symptoms six months after the injury, and the character of the findings leave no doubt that the meningo-encephalitis was a terminal accident and had nothing to do with the causation of the insanity in this case. Alcohol as the predisposing cause, and the concussion of the brain and pressure of hemorrhage caused by the severe trauma—a motor car fracturing the base of the skull—as the direct exciting causes, present much more probable claims for recognition as etiological factors in this case.

I think the multiplicity of cause in insanity can be distinctly enunciated from common ground. From the same point of understanding, complexity of cause must be admitted. It is this complexity which makes it questionable whether we are justified in allowing singleness of cause in any given case. A number of preparatory conditions, if present, would explain the ease with which a single incident, like traumatism, might be a determining factor. These conditions may be:

1. The neurotic temperament; 2, hereditary predisposition to insanity; 3, acquired predisposition; 4, operation of some great moral stress.

Regarding the first, I can do no better than refer to Duret's well-known essay, "Sur les Traumatismes Cerebraux," to show how in the neurotic type injury might give emphasis to the nervous phenomena resulting from irritation to the dura mater. His conclusions are as follows:

1. That the dura mater is abundantly supplied by sensory nerves from the fifth pair, by anterior, middle, and posterior branches. He suggests the possibility of special terminal organs, which increase the delicacy of the sensibility of the membrane and account for the marked "physiological" troubles ensuing on their irritation.

2. That irritation of the dura mater, especially of its inner surface, causes pain.

3. That irritation of its nerves causes reflex movements in both voluntary and involuntary muscles, but not so local or definite as those caused by irritation of the cortex. They are not more localized than those caused by irritation of peripheral sensory nerves.

4. His cases of purposely-produced depressed fractures of the skull in animals showed all the reflex results, as of irritation of the dura mater, both on the same and on the opposite side; and not as of direct cortical irritation. He made this clear by finding, post-mortem, the cortex *uninjured*. If a *superfluous amount of violence* was used, the symptoms were rather those of cerebral commotion.

5. That the secondary contractures, which follow injury, are due to dura mater reflexes, appearing almost indiscriminately on the same and opposite sides.

6. That reflex vasomotor disturbances are also the result of irritation of the nerves of the dura, consisting in spasm or paralysis of cerebral and ocular vessels, and that light is thus shed on the causation of secondary effects of cerebral traumatism, through the agency of cerebral vascular conditions.

From these conclusions of Duret, it can readily be seen *that an injury producing such a degree of irritation* to the membranes as to cause spasms, contractures, and paralysis could also cause such an amount of disturbance to the integral cell elements of the cortex as to induce a condition of insanity.

In predisposition both by heredity and that acquired, as by the taking of some toxic, such as alcohol, it must be admitted we have a cell tissue of lessened potentiality to resist and to inhibit. With such an established condition of the cerebrum, the commotion caused by either a direct impact on the brain, or that brought about by the reflex effect of some more distal traumatism, might be sufficient to establish a positive pathologic state, associated with symptoms of insanity.

The fourth possible predisposing condition includes those who at the time of the receipt of a cranial injury are suffering from some great moral stress. The depression of the vital functions, incidental to a bereavement, a loss, or a disappointment, should not be discounted. While moral causes should be weighed with allowance, we are forced to note their inhibiting effect upon the heart's action, as well as that upon the secretory functions. How this in turn harasses the whole digestive tract, and blocks the assimilation! Every organ of the body suffers from want of proper nutrition. The brain is among the earliest to succumb. Must we not grant that an impoverished brain is a most susceptible organ; and that an injury, though slight, under such conditions might prove a source of mental disturbance. The conclusion we can reasonably draw is that an injury to the cranium, received upon such a basis of predisposing conditions as above enumerated, should not be estimated as the cause itself, but as the final determining factor of the mental disorder consequent to it. The causes of insanity are so complex that I doubt if we are justified in saying that injury is a cause in itself.

Kiernan estimated that in 45 of the 2200 patients under his care, the disease was due to traumatism. Hay found 60 cases in 2500. Starr, in "Brain Surgery," says that 2 per cent. is a fair estimate. Clouston ascribes a few cases of insanity to blows on the head, falls, and other traumatic injuries to the brain. He says, "We have had twelve cases of traumatic insanity and the insanity of sunstroke sent to the Royal Edinburgh Asylum in the past nine years, which is only .33 per cent. of the admissions." Krafft-Ebing says traumatism is a common factor in the cause of insanity, and yet found but 1 per cent. out of 462 cases. It is doubtful if experience and close observation will bear out the truth of the statement as to its being a common factor. I find in the Columbus State Hospital, with 1400 patients, 10 cases, or .7 per cent., which might be regarded with some certainty as due to traumatism of the brain.

The question of interval of time between the occurrence of the injury and the insanity should be carefully considered. Dr. J. Christian[1], analyzing 100 cases of traumatic insanity, finds in 54 cases the interval was from 1 to 5 years; in 21 from 5 to 10, in 11 from 10 to 20, in 7 from 20 to 30, and in 7 more than 30 years.

In the ten cases in the Columbus State Hospital, the time between the injury and the initial symptoms of insanity varied from the time of the injury to fifteen years, often with no other evidence that the injury was a causal factor than that the mental disease followed it in time.

Two other considerations are now to be borne in mind: 1, the kind of an instrument producing the blow, and the kind of an injury received from a fall; 2, whether these agents produce a localized or a diffused effect.

From the analysis of twelve cases in the American War of the Rebellion, locality of injury is an important point.

In 3 cases the middle, in 4 the anterior, in 1 the posterior fossa was affected; in one case the anterior and posterior fossæ, in 1 the middle and posterior fossæ, in 2 cases the anterior and middle fossæ were affected.

From this it appears that injury to the base of the skull is most prone to yield subequent mental disturbance, and that the middle fossa is more frequently involved than the other parts.

SUMMARY.

1. Conditions already present may predispose to the causing of insanity by an injury.
2. The insanity should speedily follow the injury.
3. The extent of the concussion may be a determining factor.
4. The locality on the cranium may be an important consideration.

DISCUSSION.

Dr. Hough—It is the fortune of the general practitioner to see not infrequently cases of injuries to the head, which, while not making the sufferer necessarily an inmate of an insane asylum, to a certain extent incapacitate him for the subsequent following of his occupation. A typical instance is a carpenter of middle age who was struck by an electric car, producing fractures of the skull. He recovered from his injuries; there was no paralysis at the time, but a year afterward he came to see me, and told me—and his wife corroborated his assertion—that his memory was seriously impaired; that there was a certain amount of difficulty in using the left arm, and that he had been unable to do any work since the accident. That class of permanent result from head injuries is by no means uncommon.

Dr. Richard Dewey, Wauwatosa, Wis.—I was struck, while listening to the paper, with one fact which has arrested my attention before in traumatic cases; that was the association of alcoholic excesses. In a considerable number of my cases excess in alcohol was closely associated with the insanity or with injuries of the brain in some cases not associated with insanity, so much so that it has been questioned whether, without the added element of alcoholism, the condition of insanity would have developed. The fact that there are many cases in which very severe injuries of the head are recovered from without serious results, without insanity developing seems to indicate that this may be the case.

Dr. G. W. McCaskey, Fort Wayne, Ind.—I wish to refer to one case that came under my observation three or four years ago. The patient was examined with a view to securing a pension. During the Civil War he was in action and was supposed to have been killed. He was evidently left comatose upon the field. He disappeared and was not found for several years. During all this time he had forgotten his own identity. After four or five years he regained consciousness of his own identity. During this time, so far as could be traced, there was no great amount of aberration in performing the menial duties which he assumed. Very suddenly his identity returned to him, and he came home. The case was interesting to me because of the sudden loss of consciousness of his identity and its sudden return. Careful examination of the head showed no external sign of injury whatever, and I presume there was nothing more than concussion, although there may have been a fracture of the inner table.

Dr. T. J. Happel, Trenton, Tenn.—I am surprised at the statement that there are so few such cases. Within the last few months I have come in contact with three; one case in which trephining was done to relieve a weak-minded condition, which was the result of an injury. I know a man in active business, with an irritable mental condition, owing to cranial injury; and during the last few months I saw a man who had a history of having been struck with an iron on the head during the late war, and was recently again struck with a stick on the head and at once developed acute mania.

Dr. Drayton, New York—It is indeed fortunate that there are so few instances in which the results are serious. When we consider the free use of the club in some of our cities by those who are supposed to be authorized to use their batons of office, we can congratulate ourselves that in nearly all of these cases of severe injuries to the head there is prompt recovery. I can recall two or three instances in which there was very marked insanity of the acute order for several months. I gave a happy prognosis to those interested in the victims, and that prognosis was verified by a subsidence of the symptoms and the return of the individuals to their vocations and former ways of life. I therefore say that society should be congratulated on the very happy treatment by nature of these cases, and that we have so very few instances in which the results are chronic. Nevertheless, I am far from advocating a policy in the management of municipal affairs that is indifferent to the manner in which the policeman employs his club.

Dr. E. T. Carpenter—The fact of the case becoming insane by an accident, and being speedily operated on, does not argue that the case would have recovered without the operation, and at the same time does not argue really that the accident was the direct cause of the condition, notwithstanding I say in my conclusions that the insanity may occur speedily after the injury. The location of the injury has something to do with causing the insanity. I have a table of the cases during the War of the Rebellion which shows that injuries to the base of the skull are most apt to result in mental disturbances.

MEASUREMENTS OF CHICAGO SCHOOL CHILDREN.*

W. S. CHRISTOPHER, M.D.

Professor Pediatrics, Medical Department, University of Illinois; Professor Diseases of Children, Chicago Policlinic; Chairman Child Study Committee, Chicago Board of Education.

CHICAGO.

For the past year measurements of children in the Chicago public schools have been made under my direction. The work was started March 6, 1899, and continued throughout the remainder of the school year with Mr. F. W. Smedley and Mr. C. Victor Campbell as operators. This corps was increased in September by the addition of Messrs. Donald P. McMillan and C. C. Krauskopf as paid assistants, and Miss A. Loesch as a voluntary assistant. Mr. F. W. Smedley, who heads the corps, had been engaged for a number of years in laboratory work in physiological psychology in the University of Chicago, previous to his appointment for this duty by the Board of Education of Chicago. He is a man of large experience, thoroughly scientific, and eminently qualified for the work. The remaining assistants were appointed after competitive examination; of these, Mr. McMillan and Miss Loesch had also previously had extensive experience in laboratory psychology, and Messrs. Campbell and Krauskopf were teachers of ability and standing. From the personnel of the corps of observers, I am justified in claiming for the results an unusually high degree of accuracy. My own part in the matter has consisted in determining the observations to be made, watching the work, and later, in discussing the results in conjunction with Mr. Smedley.

Last year the work included only the determination of the following points, with each pupil: Height; height sitting; weight; ergograph work; strength of grip, right and left; hearing, right and left; "vital capacity." The observations were limited to these few points in order that as large a number of pupils as possible could be examined. In all, about 1200 pupils were examined from March to June, inclusive, and the results obtained were so encouraging that the Board of Education agreed to continue the work and established as a permanent part of the school system a department of "Child-Study and Pedagogic Investigation," and appointed Mr. Smedley as director of the department. I believe this is the first instance of a municipal board appropriating money for research work, a fact which redounds greatly to its credit. During the present school year the same observations have been continued, in order to obtain sufficient number of observations to establish reliable norms; the total number now, April 22, 1900, amounting to 5636. In addition to these observations, sight tests have been made. Acuity of vision has been determined by Snellen's cards, and examinations have been made as to color-blindness. In addition to this, obvious developmental defects have been noted, and signs of fatigue and nerve-strain recorded.

DESCRIPTION OF INSTRUMENTS AND METHODS.

In measuring height, and height sitting, a stadiometer of the Bertillon pattern has been used. In taking heights, the height of the heels has been accurately calipered and subtracted from the gross height, giving a net height, which was found on trial never to differ from the height measured in stocking feet more than 2 millimeters, and to present an average error of about 1 millimeter.

The weights were taken with ordinary schoolroom clothing. Last year 121 children brought back their clothing to be weighed. This was in the latter part of the month of May, 1899, and it was found that the clothing ranged in weight between 2.8 and 8.2 per cent. of the gross weight of the child. The average weight of boys' clothing was 5.8 per cent. of the entire weight, and of girls' clothing was 5.5 per cent. of the gross weight of the individual. The clothing in the great majority of the cases ranged between 4 and 7 per cent. of the gross weight.

Strength of grip was measured until recently, by an ordinary two-spring dynamometer, graded in kilograms This dynamometer was tested from time to time to insure its accuracy. Lately an adjustable dynamometer, invented by Mr. Smedley, has been employed. This dynamometer is adjusted to the size of the hand. Each pupil is given several trials of strength, and the best result obtainable is recorded.

The old term "vital capacity" is employed to designate the amount of air which can be forcibly expired. Two wet spirometers were employed, one made especially for this work and one purchased from the Narraganset Machine Company. As neither differs materially from the ordinary wet spirometers, a detailed description seems unnecessary. In using the spirometer each child tested was given several trials, and the best obtainable result recorded.

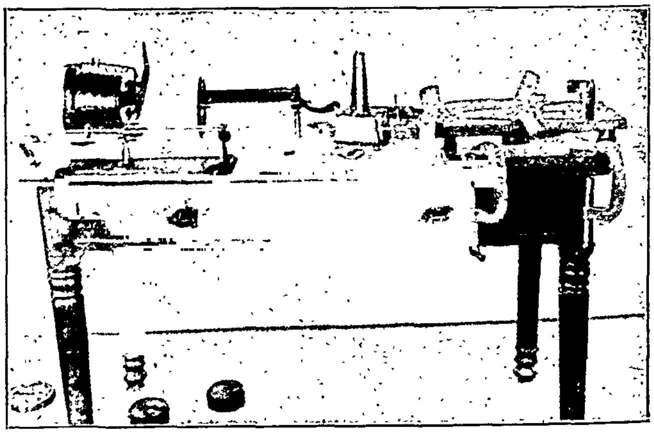

Fig. 1.—Ergograph.

Hearing was tested with the audiometer invented by Prof. C. E. Seashore, of the Iowa State University. This is an electric apparatus in which the loudness of the sound produced is definitely determined by resistance-coils. It is graduated by an arbitrary scale ranging from 0 to 40. The normal point on the instrument used seems to be about 11. Numbers above this represent degrees of difficulty of hearing, while lower numbers indicate special acuteness of hearing. I am not yet ready to present the results of the tests on hearing.

Fatigue and endurance were tested with the ergograph shown in Fig. 1. The instrument employed was Mosso's ergograph, modified by Mr. F. W. Smedley.

DESCRIPTION OF ERGOGRAPH.

The apparatus consists of two parts, a fixing board, and a traveler mounted on a suitable frame. The forearm is placed on the fixing board in the prone position, and held in place by suitable straps and clamps. There are also clamps to hold down the index and third fingers, leaving the middle finger free. It is the design of the apparatus to hold the forearm so firmly in position that only the flexors of the middle finger can be brought into action. This it does not accomplish perfectly, but as the error is common to all those examined, the influence of the error is practically eliminated in comparative results. From the traveler two cords extend, one toward the fixing board, carrying a clamp to attach it to the free middle finger of the subject examined; the other, extending in the opposite direction over a pulley, is provided with a device for holding weights. Attached to the traveler and extending laterally, is an arm which carries a pen, which, in its turn, bears upon the surface of the drum of a kymograph. Attached to the side of the frame is an endless tape, which is carried forward with each return movement of the traveler, and thus sums up the total height which the weight is lifted. The ergograph was operated in the following manner: The child's forearm being clamped in position, the cord from the traveler was clamped to its middle finger, and the pulley-cord loaded with a weight equal to 7 per cent. of the weight of the child. On flexing the finger the weight was lifted, and the pen made a corresponding mark upon the kymograph. On extending the finger the traveler dropped back to its original position, the measuring tape was advanced a distance equal to the height the weight had been raised, and the return stroke on the kymograph was made. By the aid of a metronome these flexions and extensions of the finger were made each second, so that in ninety seconds, the time employed in each experiment, the weight should be lifted forty-five times. The actual number of lifts, however, varied occasionally from this number, reaching forty-eight or forty-nine in some instances, and not quite equaling forty-five in others. In all cases, however, the work was continued for ninety seconds, and the amount of work done in centimeter-kilograms recorded. In the case of very obese pupils it is to be noted that 7 per cent. of the total weight, including as it did 7 per cent. of the weight of the fat, as well as 7 per cent. of the weight of the active tissues of the body, proved to be excessive, and they were unable to continue to move the weight throughout the whole period of ninety seconds. Nevertheless the actual work done came out in centimeter-kilograms, and was suitable for comparisons.

* Read before the American Pediatric Society, Washington, D. C., May 3, 1900.

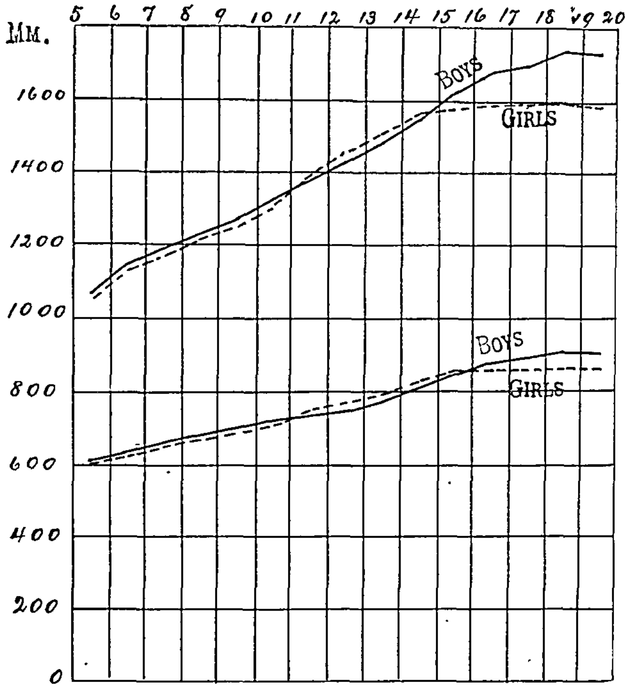

Fig. 2.—Growth in Height—Standing and Sitting.

Note.—The stature of girls is less than that of boys up to the age of 11, when the girls surpass the boys and remain greater in stature up to the age of 14. After 14 girls advance in stature very slowly and very slightly, while boys continue to increase until 18. This fact is in harmony with the common observation of the earlier occurrence of puberty, with its greater activity, in girls than in boys. The lower lines representing height sitting, show that in this measurement girls also surpass boys at the same age, as in stature. But they maintain this superiority in this measurement for one year longer than they do in stature, which means that the more rapid growth of the boy at this age is in the lower extremities rather than in the trunk.

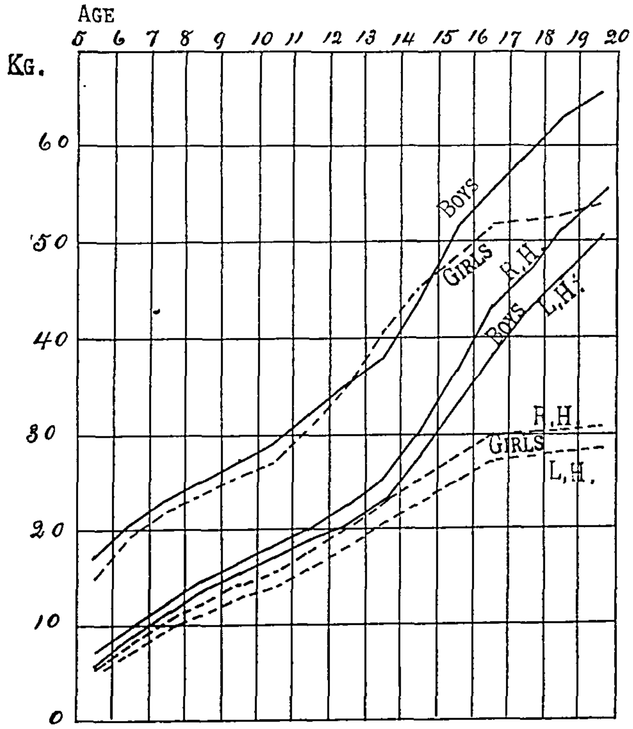

Fig. 3.—Weight and Grip.

The upper lines show the weight-curves of boys and girls. On comparison with Fig. 2 it is seen that the weight of the girl surpasses the weight of the boy, something over a year later than her stature surpasses his; and the curves recross at the same age in weight and height, so that the girl holds her superiority in weight over the boy for a shorter period than her superiority in stature. The curves also show that while the stature of girls increases very slowly after 14, the weight continues to increase rapidly to 16 and less rapidly thereafter. The grip-curves shown also in this figure indicate marked increase in the rate of gain in grip in boys commencing at the age of puberty—a gain which continues, at least as far as our own observations go. In girls, no such acceleration in muscular strength at puberty is shown, and after 16, practically no increase in strength of grip occurs. This chart, therefore, exhibits the period of life at which, and the extent to which, the well-known muscular differentiation of the sexes occurs.

From these measurements a table of norms has been computed. In these tables, the ages refer to the age at the last birthday. The number of each age examined is also given. In accordance with the general practice, the norms are expressed in medians instead of averages. In other portions of this work where small numbers are dealt with, averages are employed in the belief that they are more correct with small numbers. These tables of norms are based upon the examination of 5636 children, 2537 boys and 3099 girls, which include all examined to April 22, 1900. They consist of the pupils in the Alcott, Kozminski, Andersen and Tennyson grammar schools, together with the eighth grade and kindergarten pupils in the Hoyne school, the kindergarten pupils in the Burr school, and also the pupils in the Lake View High School, and about half the pupils in the Englewood High School, at which latter school the work of examination is now going on. In all of these schools, with the possible exception of the Andersen school, the pupils are largely of American parentage, *and are the children of parents in comfortable circumstances* and are uniformly well fed and well clothed. They therefore may be taken to represent normal American children *in comfortable circumstances.* The children at the Andersen school, about 1600 in number, are less favorably situated, and the medians obtained from that school alone, are, as a rule, less than those from the other schools. In the medians given in the tables all of the schools mentioned are included.

TABLE 1. NORMS FOR BOYS.

Age.	Number examined.	Height. mm.	Height Sitting. mm.	Weight. kg.	Work. cm. kg.	Grip. R. kg.	Grip. L. kg.	Vital Capacity. c.c.
6.	224	1134	636	20,550	103.8	10	9.5	1100
7.	230	1190	658	22,550	135.9	11·5	11	1250

19.	20	1733	918	66.000	705 2	54 5	52	3850
20.	6	1709	906	68,050	809 1	58.5	49	3500

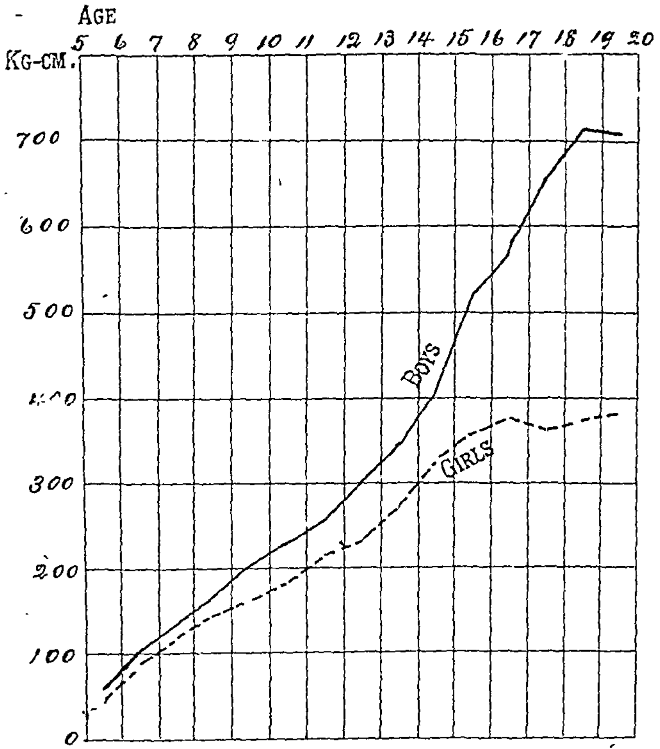

Fig. 4.—Ergographic Records.

Ergographic work is an index of general endurance. The chart shows that up to the age of 14 the girls' power is a fairly constant percentage of the boys'. From 14 years on the girls' endurance remains practically stationary, while that of the boys not only continues to increase, but increases at even a greater rate than it had previously.

The accompanying charts, Figs. 2, 3, 4 and 5, illustrate graphically the facts given in the foregoing table of norms.

ERGOGRAPHIC WORK.

The ergograph gives two kinds of information concerning the individual tested. 1. It shows the amount of energy which the individual exerts in a fixed time, and under fixed conditions. This energy may be, and in this work is, expressed in centimeter-kilograms, which affords a means of comparing the ergographic work of different individuals. 2. The ergographic tracing, or ergogram, made coincidentally on the kymograph, exhibits the manner in which this energy has been exerted.

In operating the ergograph, as previously described, loaded with 7 per cent. of the gross weight of the individual, it was found that some time between 90 and 150 seconds of work, such fatigue was produced as to render it impossible to move the weight at all. After working the ergograph to complete exhaustion, the flexors involved remained sore for several days. Inasmuch as it would be unwise to submit large numbers of school children to such inconvenience the limit of ninety seconds of work was adopted. In this limit the strongest pupils would begin to show fatigue, and very obese pupils would become completely exhausted before the time had expired. With kindergarten pupils, the ergograph can not be used, and, indeed, it can hardly be considered reliable with children under 7 years. At this age and above, however, *its use is very satisfactory.*

TABLE 2. NORMS FOR GIRLS.

Age.	Number examined.	Height. mm.	Height sitting. mm.	Weight. kg.	Work. cm. kg.	Grip. R. kg.	Grip. L. kg.	Vital Capacity. c.c.
6.	203	1127	626	19,900	93	9.3	8.5	1000
7.	238	1180	655	21,850	114	10.5	10	1100
8.	232	1231	674	23,913	141.8	11.5	11	1200
9.	221	1276	690	26,300	168.6	14	13	1350
10.	240	1321	709	28,488	182.7	15	14	1450
11.	225	1383	736	31,225	218.4	18	16	1600
12.	248	1441	762	35,725	237	20	18	1700
13.	256	1522	798	40,700	277.8	23	21	1900
14.	278	1563	830	46,312	336	26	22	2063
15.	328	1571	841	48,925	349 2	28	25	2225
16.	284	1596	849	51,988	374 6	30	27	2300
17.	198	1597	850	51,838	358.8	30	27	2300
18.	105	1600	863	52,675	368	30	28	2350
19.	30	1595	851	53,788	376 9	31	28.5	2400
20.	13	1581	834	49,175	352·8	29.3	25.5	2300

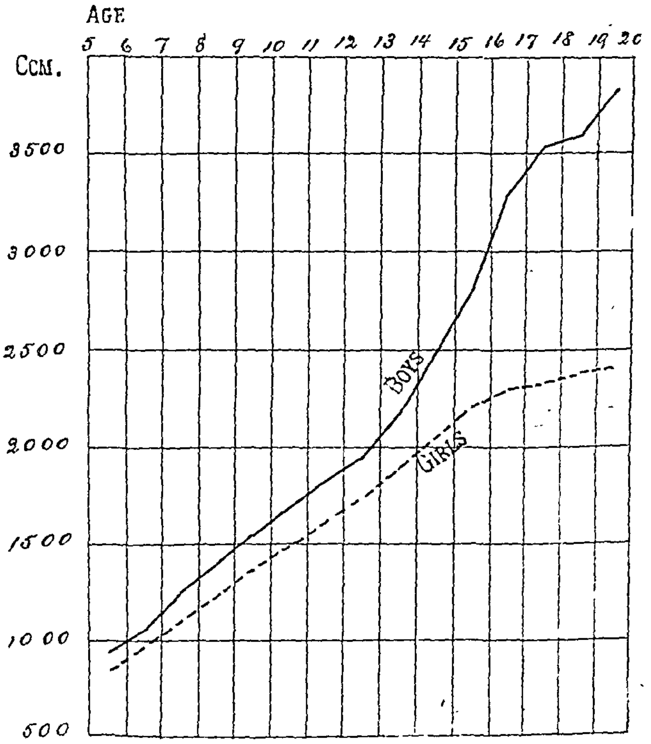

Fig. 5.—Vital Capacity.

The term "vital capacity" is here used in its old sense of volume of air emitted in forced expiration. The curves in Figs. 4 and 5 appear on comparison to be almost duplicates of each other, indicating a remarkably close relationship between "vital capacity" and endurance as shown by the ergograph. Which of these is cause and which effect, I have no means of determining.

The normal ergographic work at the different ages is illustrated graphically in Fig. 4.

On examining this chart, it is seen that at all ages girls exhibit less endurance than boys, but that up to the age of 14 the girls' power is a fairly constant percentage of the boys'. After 14, however, a marked change occurs. From 14 years on, the girls' endurance remains practically stationary, while that of the boys not only continues to increase, but even increases at a greater rate than it had previously.

Such a fact seems of prime importance. It must have some bearing on the development of the growing girl, and especially on the development of the reproductive organs. It is a factor which ought also to be taken into account in school work.

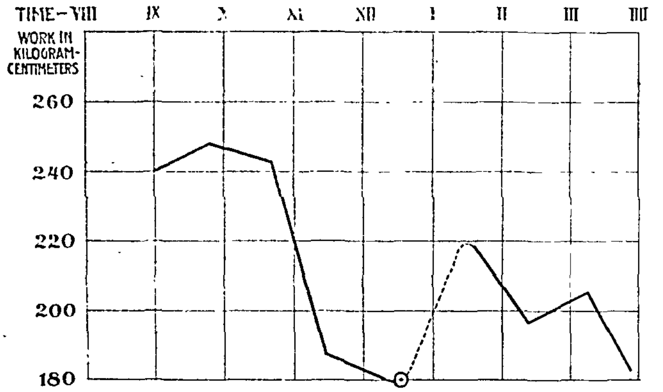

Fig. 6.—Course of power throughout the school day, as determined by the ergographic records made by R. H.

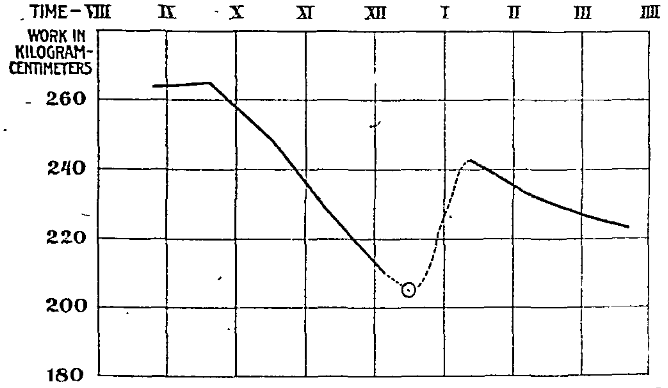

Fig. 7.—Course of power throughout a school day as determined by the average ergographic records of eight pupils of the Alcott School.

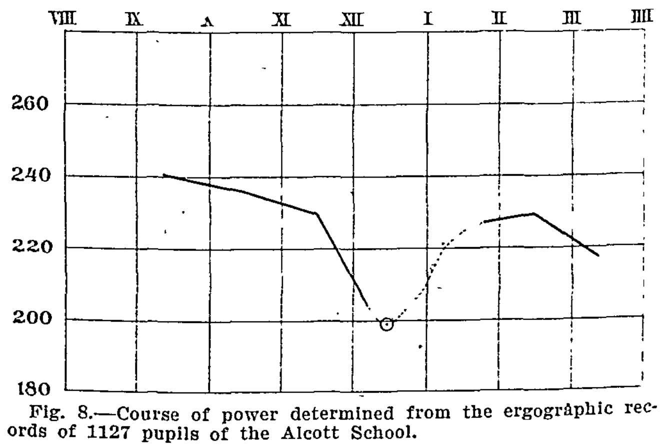

Fig. 8.—Course of power determined from the ergographic records of 1127 pupils of the Alcott School.

In determining the variation in the course of power during the day, observations were made on one individual at the Alcott school, at intervals of about forty minutes, and also on eight pupils at about the same intervals the latter results being grouped and averaged. In addition, the results by hours of the whole school, obtained through the three months of examination, were charted. In examining the school, all the children in one room were taken one at a time until all had been taken, and inasmuch as not more than twenty could be examined in the course of a school day, children of all ages were found very evenly distributed throughout all the hours of the school day. The results obtained are shown in the accompanying charts, the resemblance of which to each other is certainly striking. (Figs. 6, 7 and 8.)

Fig. 6 shows the course of power during the day of the single pupil, R. H. Fig. 7 shows the course of power during the day of the eight pupils. Fig. 8 shows the course of power during the day of all the pupils in the Alcott school. At the time these observations were made the pupils of this school did not have the usual morning recess.

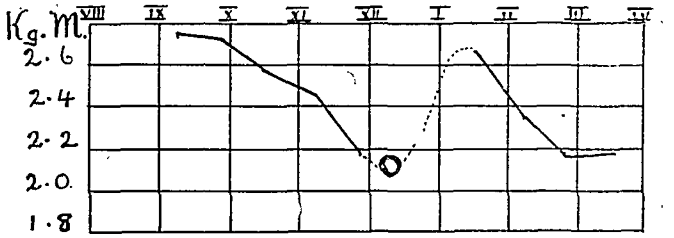

Fig. 9.—Course of Power during the day—Tennyson School—of all the pupils tested.

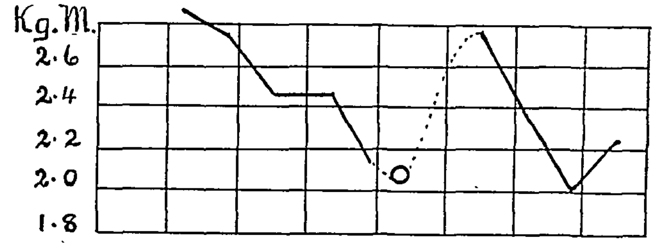

Fig. 10.—Of those Irregular in their Work.

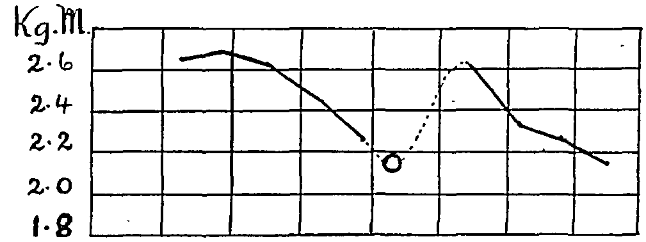

Fig. 11.—Of those Doing Regular Work.

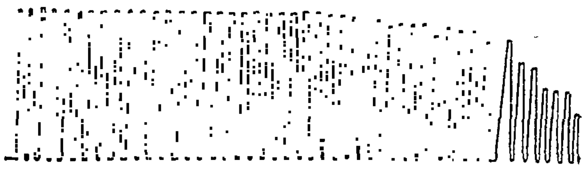

Fig. 12.—2:00 p.m. 3.7 kg. 150 cm. 46 lifts.

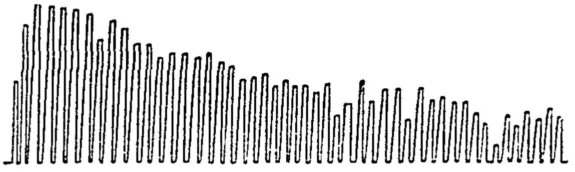

Fig. 13.—2:20 p.m. 3.9 kg. 92 cm. 49 lifts.

The charts show that the child is at its best during the first morning hour, and that after 10 a. m. its power decreases somewhat rapidly. They also show that in the afternoon the power does not reach the maximum shown in the morning, but it is better maintained, the curve not decreasing so rapidly.

An interesting confirmation of this matter was unexpectedly obtained at the Tennyson school. At that school it was decided to take the course of power, during the day, of twelve pupils. In the case of four of them, the results did not tally at all with previous experience, these four showing unusual power in the afternoon. Upon investigation it was found that the teacher of these four had been called from school in the afternoon, and that they had had no work, but had employed themselves, as they said, in having a good time.

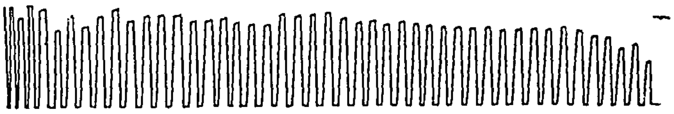

Fig. 14.—9:00. 80 cm.

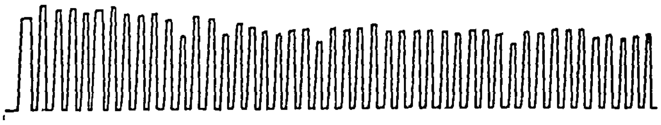

Fig. 15.—9:47. 83 cm.

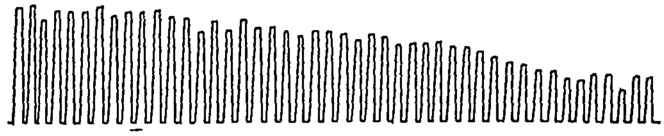

Fig. 16.—10:40. 81 cm.

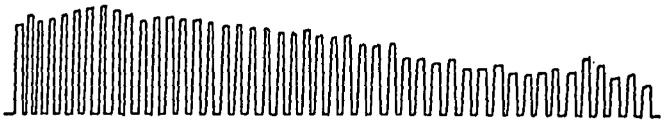

Fig. 17.—11:30. 63 cm.

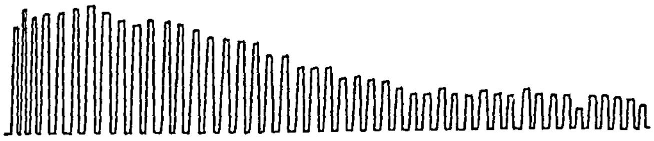

Fig. 18.—12:18. 60 cm.

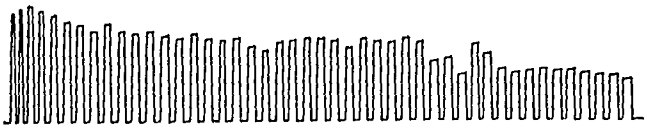

Fig. 19.—1:34. 73 cm.

The charts illustrating these facts are shown in Figs. 9, 10, and 11.

The ergogram, illustrating the manner in which the energy is exerted, often gives most interesting information. In Fig. 12 is shown an ergogram produced by a robust man, whose muscles are well controlled, and whose strength is good. In Fig. 13 is shown the ergogram of a so-called "nervous" child, one whose inhibition is defective and whose efferent nerve impulses are erratic. The want of muscular control is shown by the irregularity in the heights of the lifts, the uneven spacing, and the excessive number of lifts, showing the failure to keep time with the metronome. The ergograms of R. H., whose course of power throughout the day is shown in Fig. 6, are given in Figs. 14-22, inclusive. With each ergogram is given the time at which it was taken, and also the total height the weight was lifted. Fig. 23 shows the best woman's record. Fig. 24 shows best boy's record for height lifted. Fig. 25 is the ergogram of a sprinter. This ergogram, which is unusually strong at the beginning, shows sudden dropping off, with complete exhaustion at the end of thirty-four lifts, or seventy-eight seconds. This boy, 18 years old, says he runs distances up to 300 yards, but can not run 330 yards. Fig. 26 is one of especial interest to medical men. It was made by a girl, aged 14, who was suffering from chorea. The tracing is certainly typically choreic in its irregularities, but the great interest lies in the exhibition of endurance. The work was continued for three full minutes without any evidence of approaching exhaustion. It was stopped at this point because the end of the paper on the kymograph had been reached. The output of energy is enormous.

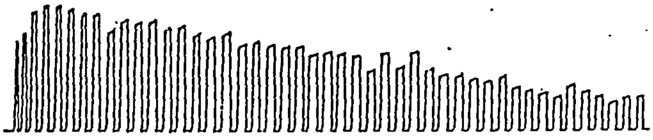

Fig. 20.—2:20. 66 cm.

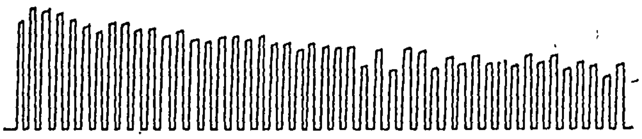

Fig. 21.—3:13. 69 cm.

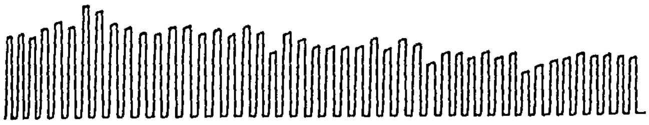

Fig. 22.—3:55. 61 cm.

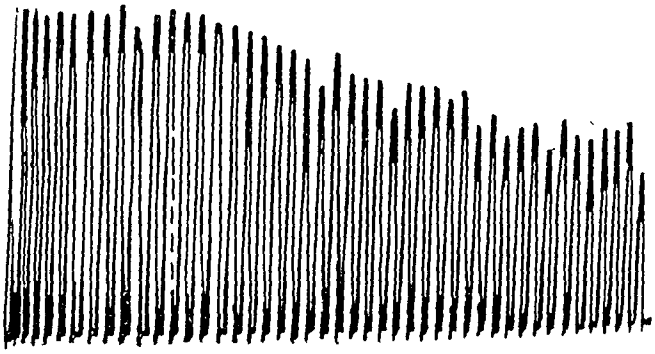

Fig. 23.—Best Woman's Record. Age 17. Plays piano very little. 2:30 p.m. 3.7 kg. 231 cm. 44 lifts.

From *La Fatigue Intellectuelle*, by Binet and Henri, I take Figs. 27 and 28. Fig. 27 shows four ergograms taken by Mosso from Dr. Maggiora, professor of hygiene in the University of Turin. The weight used was 2 kilograms. What relation it bore to the weight of Prof. Maggiora is not stated. The first of these tracings was taken while Maggiora was in a state of rest and before holding an examination. This examination commenced at 2 p. m., lasted three and one-half hours, and was very trying; besides the labor of the examination, there was also the "emotion of feeling the responsibility of his own teaching in the presence of competent colleagues, who assisted as members of the examining commission and who were capable of judging him." The second tracing was made at 5:45 p. m.; the third at 7:30 p. m., and the fourth at 9 p. m. The last three indicate very slow recuperation. In Fig. 28 are shown three ergograms made by the left hand of Maggiora on the same occasion, the weight used being 500 grams. The first of these was taken at 9 a. m., the second at 5:30 p. m., and the third at 7 p. m. The two experiments, however, differ in a very important particular. The tracings shown in Fig. 27 are voluntary tracings, presumably made with the right hand, although that fact is not specifically stated in the only account of the matter at my disposal. The tracings of Fig. 28, however, were not made voluntarily, but instead the muscles were excited to action by electricity. The marked similarity in the curves indicates that the fatigue is not entirely central. Kraepelin and Hoch[1] have arrived at the conclusion that the height of the individual lifts in the ergogram depends on the state of the muscles, while the number of the lifts depends on the state of the central nervous system. Important as is this part of the subject, I can not occupy your time with it further, but must proceed to another phase of my work.

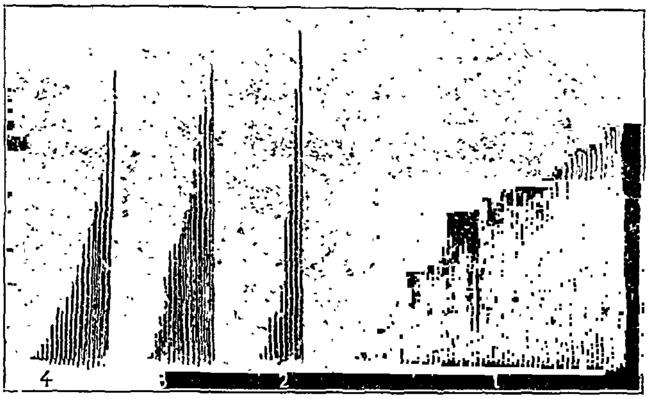

Fig. 27.—Ergograms of Maggiora—Voluntary.

Fig. 27 illustrates ergographic tracings taken by Mosso from Professor Maggiora, of Turin. Tracing No. 1 was made with the right hand while in a state of rest before conducting an examination. Tracing No. 2 was made 15 minutes after the conclusion of the examination; tracing No. 3, two hours after the examination, and tracing No. 4, three and one-half hours after the examination. The last three tracings indicate the intense fatigue produced by the work, and slow recuperation. The greater height to which the weight is lifted in this tracing indicates apparently less nervous control during the fatigued state.

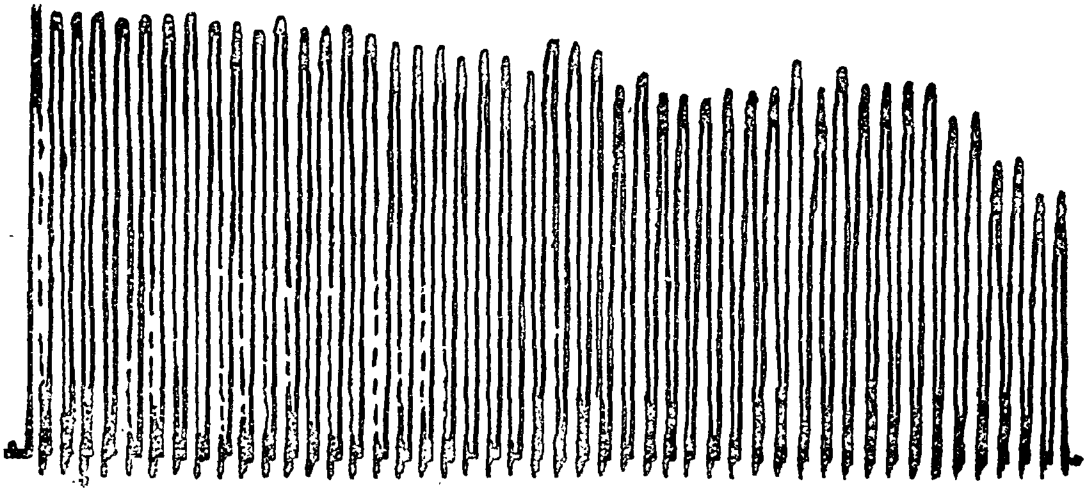

Fig. 24.—Best Record for Boys, for Height Lifted. Age 18. 9:55 a.m. 3.7 kg. 266 cm. 47 lifts.

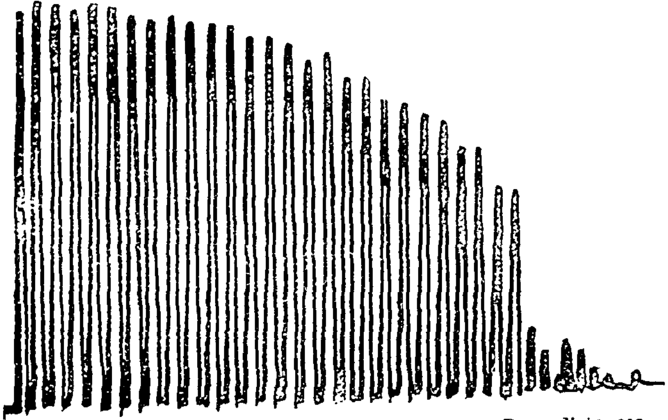

Fig. 25.—Ergogram of a sprinter—18 years old. Runs distances up to 300 yards. Said he could not run 330 yards. 2:45 p.m. 4.8 kg. 114 cm. 34 lifts.

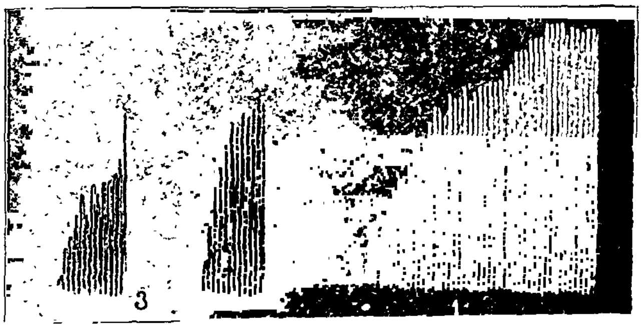

Fig. 28. Ergograms of Maggiora—Electric Stimulation.

Fig. 28 illustrates ergograms of Professor Maggiora made with the left hand upon the same occasion as shown in Fig. 27. In this experiment electrical stimulation was substituted for voluntary action.

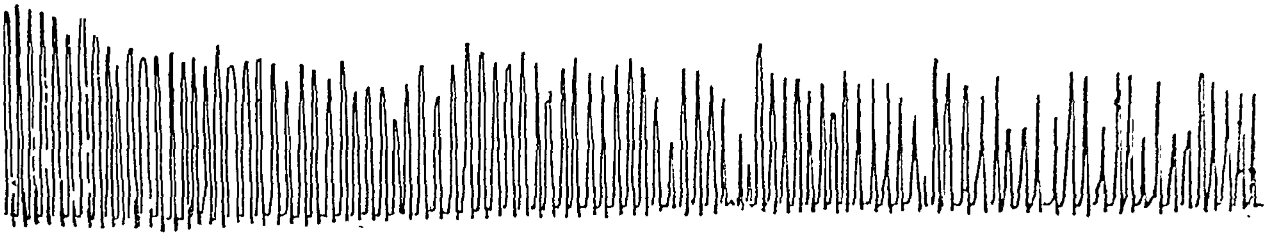

Fig. 26.—Kitty S. Age 14. Chorea. 2:00 p. m. 2.6 kg. 3 min. 94 lifts.

EXOPHTHALMIC GOITER.*

F. W. HIGGINS, M.D.
CORTLAND, N.Y.

This is one of those puzzling and tantalizing diseases which will baffle a full explanation. All disease is mysterious, but we are beginning to feel that the pathology if not the treatment of diphtheria, Bright's disease, or tuberculosis is somewhat satisfactory. Many diseases of the nervous system have a beautifully exact anatomical lesion. But exophthalmic goiter, one of the most striking entities of them all, is most elusive.

The symptoms are fairly definite and yet I believe that the disease often remains unrecognized. This is so for the reason that one or more of the main symptoms may be absent or slightly in evidence. The rapid pulse is the most constant and easily detected. A pulse above one hundred, when the patient is not excited or under exertion, should arouse suspicion of this disease. Still, this marked symptom is absent in a certain percentage of cases.

The enlarged thyroid, which gives its name to the disease, if looked for carefully by deep palpation, is present in probably 90 per cent. of all cases. It is not generally so large as in simple goiter, nor so hard. It more resembles a vascular fullness. Sometimes a patient will present herself complaining most of the large neck, but very often this member of the tripod of symptoms must be searched for. This is especially so since from 95 to 97 per cent. of the cases occur in women. One side is frequently decidedly larger than the other.

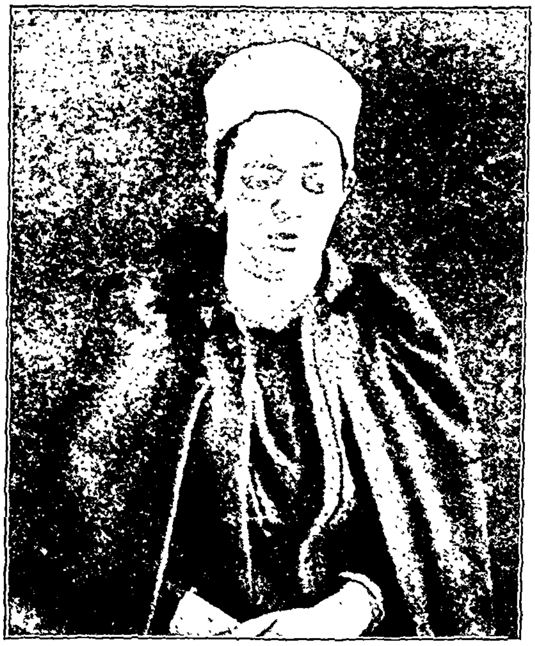
The exophthalmos is perhaps the most variable of the three cardinal symptoms, but may be the most striking. This was true in a case recently under my care. I present a photograph as she appeared in my office for treatment for the eyes. They had protruded to such a degree that the lids could not cover any portion of the cornea. As a result of exposure both had ulcerated. The extreme chemosis of the ocular conjunctivæ had pressed the lids still farther apart until they were immovable. At this point she had come under the care of a physician, who had recommended poulticing the eyes. The result was that the eye first affected resembled a prolapsus ani. The cornea had sloughed and its location was manifest only by a sulcus in the middle of the edematous conjunctiva over the shrunken, protruding ball. It may be mentioned that the worst eye was on the side opposite to the side of the thyroid most enlarged. This is contrary to the rule, but the exceptions seem to predominate.

The right eye had been painful and ulcerated only a few days, but was evidently going the way of the other. I enucleated the eye totally destroyed. The other was treated by the patient resting in bed, by the application of frequent hot boracic solutions, atropin, and multiple scarifications. It made a good recovery, although there had been a marked hypopyon, and it was about two weeks before the lids could cover the cornea.

This amount of exophthalmos is rare and extreme, but it is in many cases a very noticeable symptom. The sclera may be visible above the cornea. Stellwag's sign is the increased distance between the margins of the upper and lower lid. Graefe's sign is the lagging, jerking downward movement of the upper lid as it attempts to follow a downward rotation of the eyeball; either sign may be absent. Various learned explanations of these phenomena exist, which include the innervation of Müller's muscle. The fact, however, remains, that the mechanism of the signs or of the proptosis itself is not understood. The only imaginable factors are a relaxation of muscle tone, an overfilling of orbital veins, and an increase of orbital fat. My own opinion is that the first factor is the most important, since, in the case just detailed, an artificial eye could not be retained in the socket from the relaxation of the lower lid.

There are other evidences of weakness of muscle fibers. The sweating, diarrhea, weak, rapid heart action, throbbing arteries, and flaccid skin must depend upon a loss of tone in the involuntary muscles; while the trembling and general weakness is due to the same condition in the striped muscle.

It is certainly remarkable that the description of a person in terror should apply so exactly to the chronic condition found in this disease, said to be generally due to fright. The staring eyes, palpitating heart, trembling and weakness, not to mention the rarer symptoms of both, as relaxed bowels, sweating, abundant urination, and mental break-down are found in each. This has led to it being included among the nervous diseases. Because no organic central changes are found present it has been called a functional disease. Certain experimental lesions on the medulla have produced exophthalmos, and we all know that the vagus controls the rapidity of the heart's action. Other functional complications, as anesthesias and paralysis, are described by Gowers. All these considerations make out a strong case for placing it in the catalogue of nervous diseases. The prevailing treatment a few years ago by galvanization of the cervical sympathetic was due to this supposed pathology.



During the last few years there has been a trend in a different direction. While admitting that the manifestations of the disease were largely that of a neurosis, it was thought that some causation beyond the depressed nerve-centers must exist. The most natural cause, reasoning from analogy, would be some form of toxemia. Thompson's explanation of the disease as an intestinal autointoxication is a marked example following this etiology. So far as I know, this theory does not find general acceptance. I must admit, however, that I do not give phosphate of soda to my patients, following his recommendation.

---

*Read before the Third District Branch, New York State Medical Association, at Binghamton, N. Y., June 21, 1900.

The asserted fact that over half the cases of exophthalmic goiter have been greatly benefited or cured by removal of the thyroid has had a most marked influence on our ideas of its character. If this is true, as is asserted by most competent authority, it must be that one of two explanations obtains.

Possibly the operations by reflex on the adjacent sympathetic or other nerve-centers modifies the general symptoms. Those who still hold to the purely nervous pathology claim this is true and cite the fact that a section of the cervical sympathetic is often beneficial. The other possibility is that the secretions of the thyroid entering the blood are of great importance normally, and that an over-action or perverted action of the gland by poisoning is the cause of all the other symptoms. This has been the controverted point during the last ten years. Most writers, I believe, admit that removal of the thyroid may be expected to cure the disease. The theories constructed on this fact, however, are most varied, and some of them appear fantastical.

The simplest of all the etiologies given is that the thyroid secretion is a complex poison to the organic nerves, that the rapidly growing gland with its increased function overwhelms those centers, and that its removal removes the cause of the disease.

Further study rather tends to dissatisfy us with this simple explanation, and presents at least four factors that should be considered. These are the physiological experiments on the thyroid, the contrast between this disease and myxedema, the possibility of recovery from the disease under other forms of treatment, and the etiology. It is impossible in the limits of this paper to enter into a discussion of each of these. I will simply try to illustrate the statement that the pathology is still complex.

Blum[1] gives careful experiments to show that the function of the thyroid is not to furnish a poison but to supply the antitoxin; that from imperfect assimilation, albumoses are produced, which it is the constant function of the thyroid to destroy by combination with an organic iodin product as iodothyrin. This emphasizes the importance of the normal thyroid, but just why an increased function of the thyroid should cause disease is not made clear. We must supplement this physiological explanation with the supposition that the antitoxin itself has an effect on the nerve-centers or that some other substance is secreted by the gland which does have such an effect.

Myxedema is a disease supposed to be due to the absence of the thyroid or a suspension of its functions. The reasons for believing this are quite cogent. Entire removal of the gland brings on the disease. Feeding the gland mitigates its manifestations.

Now, the symptoms of this disease and exophthalmic goiter are almost opposite. One has dry skin; the other moist. The first tends to a drooping of the upper lid; the second to widening of the palpebral opening. The body temperature is lowered in myxedema; in Graves' disease it is frequently raised subjectively or even objectively. In one the pulse is too slow; in the other too rapid. So the contrast in a general way holds good. But it must be added that some symptoms are common to both. Weakness, mental hebetude, insanity, expressionless face, anemia, and lessened sexual desire are examples of this. Indeed, cases are on record where the two diseases existed in the same patient at the same time. This is impossible to understand unless the functions of the thyroid are complex, or unless exophthalmic goiter is more than overaction of the thyroid.

The most common cause of the disease being a sudden fright, is also a puzzle in its pathology. One can imagine the mammary secretion being turned to a poison for a day by emotion; but that a chronic disease should be due to a sudden mental influence is not so easy to comprehend. The fact that cases have recovered under many forms of treatment besides that directed to the thyroid further complicates the question. Removal of nasal abnormalities is said to have cured the disease. Return to a healthy condition of the alimentary tract has also been followed by a recovery from the tripod symptoms.

From all these considerations it must be that underneath the lesser truths of the influence of the cervical sympathetic and of the thyroid gland and of the terror there must be a deeper cause. I am not able to give this deeper cause and shall not attempt the task. Before this can be done we must know more of the complex physiology of the thyroid. We ought also to know what set of nerve-centers are involved to give all the gross physical manifestations of a man or an animal in the extreme of terror.

My own feeling in regard to the disease is that we must now, perhaps always, attack its secondary manifestations; that there is a fright center as well as a speech center or a vasomotor center, and that this may be congenitally weakened. Last week I heard of a young wife who always felt that she should die if a burglar came into the house, and did die because she supposed her husband was one as he carefully came at two in the morning. In such a predisposed person—a woman in nine cases out of ten—sudden emotion produces changes in the heart, digestion, action of the kidney, circulation of the thyroid, size of the pupil, character of the breast milk, trembling of the limbs, flushing of the face, and so through a long list. Suppose some one of these physical manifestations, such as a disturbance in the thyroid, assumes a permanent character from an inherent predisposition. Then a vicious circle would be established in which the other temporary symptoms tend to be constantly reproduced. I know this appears to be a return to the nervous pathology, in contrast to the prevailing explanation as a disease of the thyroid. If I have made myself understood, it will be seen that the thyroid is recognized still as a prime factor, but only as one in a chain. Our treatment is influenced by this idea only to the extent that we attempt to break the chain at its most vulnerable point. If we are prepared to do this by excision of the thyroid wholly or in part, well and good. If we detect some other weaker link, or one we feel more competent to solve, our treatment may be directed there with a fair hope of success.

Significance of Tardy Adenopathy in Scarlet Fever.—Early nephritis in scarlet fever, accompanying the fever and eruption, is usually slight and transient, but nephritis occurring later frequently assumes a serious form. It usually appears insidiously with a few clinical manifestations, but the *Semaine Méd.*, of June 20, quotes Stembo to the effect that an invariable pathognomonic sign in the incipient stages is the abrupt tumefaction of the glands below the maxilla or at the back of the neck, or both combined, appearing during convalescence, after cessation of the fever and of other symptoms. The temperature rises slightly, but albuminuria and other indications of the [illegible] for four days.

MEDICAL LITERATURE AND MEDICAL WRITING.

Virchow's recent advice to writers for medical periodicals, upon which we have already commented,[1] is attracting considerable attention in American and English journals. The points he makes in favor of brevity in non-essentials; in favor of comprehensive summaries of the previous literature bearing on the subject discussed; and in favor of a judicious limitation of the number of illustrations are all well taken. They have been urged before on various occasions, both by Virchow himself and others.

There are certain general rules for good medical writing that can not be urged too often. There is the title of the article, to begin with the beginning. The indefinite, meaningless title is still entirely too frequent, especially in American medical journals. Many a valuable observation, conscientiously recorded, is buried forever because the title does not clearly and explicitly indicate the scope of the article. What a bugbear to the index makers and cataloguers are such titles as the following, selected at random from the table of contents of recent journals: "Notes from Clinics"; "Two Obstetric Cases"; "Practical Surgical Notes"; "An Interesting Case"; "A Rare Case"—the last two continue to appear in spite of repeated protests—"A Reply"; "A Reply After Two Years," etc. Let the title state as briefly as possible the main subject of the article, so that "he who runs may read" and learn at a glance whether the article is likely to be of interest at the present moment. Medical libraries constitute the classified and indexed storehouses of available knowledge, and authors should, in the interests of the survival of their mental offspring, give it such distinctive appellation that it be not overlooked and neglected by the student. That the article is brief, laying perhaps no claim to originality, being merely a statement of a few facts of interest, is no reason why it should be sent into the world a nameless child. The sum total of our knowledge is made up to a large extent of the summary of more or less isolated observations scattered through numberless journals, but brought within the scope of reference by index catalogues and indexes in general.

A table of contents, indicating more fully the nature of an article, is certainly a valuable addition. It is an amplified title, and shows the order in which the various topics are taken up in the body of the article. It induces to system and clearness in presentation. Unfortunately, medical periodicals have not adopted this plan as extensively as it has been adopted in current biological literature. It is also regrettable that a uniform system of classification, such as that of Dewey, has not been generally adopted in our libraries, public, institutional, and private. In that case the number under which an article should be classed might be printed at the top of the table of contents.

Much annoyance and loss of time are caused by errors in the references to the literature cited in articles. Every reference should be verified carefully. Bibliographic references are inserted as part of the evidence adduced and weighed by the author. They are not ornamental and do not necessarily indicate great learning and patient study and search. Lists of references may be bought; and in a recent review there occurs the damaging statement: "The bibliography is the best that money can buy"—damaging because true. Indeed, is not the matter of bibliography somewhat overdone of late? "Many authors are mere antiquarians, gathering up the chaff with the wheat, and choking their readers with the dust of their own tedious research." In giving a reference, the name of the author, the name, year, volume, and page or pages of the journal should be cited always. In case a book is referred to, its title, the year of publication, and the page must at least be stated.

At the present time illustrations are in great demand. Good illustrations are exceedingly helpful, but the blurred smutches often seen are certainly not desirable. Reproductions of X-ray photographs are frequently unintelligible, and there is nothing to be gained by the indiscriminate use of illustrations.

Finally a word concerning the long article. The merits of a scientific contribution are not to be determined solely according to its extent. A careful, conscientious study of an important problem in medicine may require a great deal of writing for the full exposition of the results, and yet the article may be brief in the sense that no words have been wasted by unnecessary minuteness of detail and tiresome discussion. Articles of this character may be classical, and it is the function of the medical press to furnish the medium of publication for work of this sort. We have as yet but few, if any, publishers whose liberality prompts the publication of scientific medical monographs. Let not the popular taste for the brief and the pointed and the easily grasped stifle the adequate and thoughtful presentation of the results of scientific investigation. On the other hand, it is well not to forget that long articles are not necessarily scientific, strange as this may seem to some whose names appear quite often in medical prints. Quality, not quantity, counts here as well as in other spheres of action The majority of articles submitted for publication could be cut down one-half, and not a thought be eliminated in so doing. The repetition of well-known facts, padding with abstracts from text-books, and words, words,

---

[1] The Journal, July 21, p. 164.

words, too often constitute the papers that appear as "original" in medical journals. And if the editor presumes to use the blue pencil in the least, the majority of authors consider it an insult. If medical writers would but appreciate that the unnecessarily long article is just as unpopular with the reader as it is with the editor, there would be fewer written.

LITHOLAPAXY IN INDIA.

The August issue of the *Indian Medical Gazette* is a special one, devoted to the subject of East Indian experience with operations for stone in the bladder. This appears to be a common affection at all ages amongst some of the Indian populations, and the experience of Indian surgeons is therefore of value, the more so since their hospital opportunities are large. The papers published in this special number do not throw very much light on the etiology of the condition, the main point in all is the method of surgical cure. One thing stands out prominently in all the communications, namely, that Bigelow's operation of litholapaxy is the one that has become the operative mainstay of the British surgeons in India, and is the best and safest resource in all ordinary cases, regardless of age. One surgeon, Capt. H. Smith, I. M. S., analyzes nearly 8000 cases of operations for vesical calculi made in the Punjaub and in a few hospitals in the adjoining provinces since 1890. Of these 6918 were litholapaxies, with an average mortality of 3.81 per cent.; 980 perineal lithotomies, with 10.71 per cent. mortality; 29 suprapubic lithotomies with 41.37 per cent., and 27 of Keith's operation of perineal litholapaxy, with 7.4 per cent. death-rate.

Further, the figures given show the comparative harmlessness of the operation in children, as 1802 of the litholapaxies were done in subjects under 6 years of age with a mortality of only 2.55 per cent., and a total of 2615 under 12, with a total mortality of 45, or 1.72 per cent. Above this age the death-rate increased according to age, being 3.43 per cent. from 18 to 55 and 5.73 above the latter age. Keegan, who is claimed as the originator of the practice of litholapaxy in young children, would certainly seem to be vindicated by these figures. Indeed, they are better than his own statistics of 2.09 per cent. mortality in 239 boys averaging 6.4 years of age, as reported in the *Lancet*, July 28, 1894, to which he refers in reply to a criticism in the recent work of Dr. Lydston. In fact, Dr. Keegan has expressly disclaimed any pre-eminent dexterity or success in the operation, though his results as given above are creditable.

The history of litholapaxy in India, where hospitals have, in some cases, hundreds of operations for calculus annually, though dating back as it does less than twenty years, would seem to put the operation easily ahead of all others for the relief of the condition, and especially in the young, if there is distinction or preference as regards age. As Keegan says, however, and in this, others of the Indian surgeons agree with him, it is an operation that requires skill, and especially experience, as well as ample appliances for the best results. It may therefore be slower in winning the favor with European and American surgeons that it has with those of India, whose clinical opportunities as regards this operation seem to be so much greater.

Forbes Keith's operation of perineal litholapaxy has also its indications and advocates in this review of the subject in the *Indian Medical Gazette;* the Indian surgeons appear to desire to extend the use of the crushing methods and the statistics they give are not unfavorable. It is probable, however, that to some extent the popularity of these has, as our East Indian contemporary suggests, affected the statistics of the cutting operations, which are not there selected in a way that makes for high-class statistical results. Be this as it may, however, the figures given appear to fairly establish the pre-eminent utility, in that country at least, of Bigelow's operation and its modifications, without regard to age conditions originally deemed of importance.

DIPHTHERIA, LARYNGITIS AND LARYNGISMUS.

While it is true that membranous laryngitis may be due to other exciting causes than the diphtheria bacillus, in actual practice almost all cases have this specific bacterium. Laryngeal obstruction, with the complex of symptoms known as croup, may, however, be due to other causes, such as spasm of the glottis, the presence of new growths or of foreign bodies in the larynx. The differentiation is, obviously, of the greatest importance, as on it will depend the appropriate treatment to be instituted. Croup, it should be borne in mind, is but a symptomatic designation, and it may be due to any one of a number of causative influences. Symes,[1] in a recent communication, describes the features of croup as follows: laryngeal stridor, cough, with a barking, "croupy" sound, a nocturnal paroxysm, great restlessness, and recession of the chest; and he considers briefly the clinical characters of the three principal varieties of disease that are attended with these phenomena, namely, diphtheria, laryngitis, and laryngismus.

Membranous croup and diphtheria are to be looked on as essentially the same disease. The condition is characterized by its gradual onset, enlargement, induration, and tenderness of the cervical lymphatic glands, increased area of cardiac dulness, the presence of albumin in the urine, the detection of membrane in the pharynx, and the presence of diphtheria bacilli, the long duration, the slow recovery, and the transmissibility. A septicemic rash may be present, and the knee-jerks are occasionally absent.

Acute laryngitis may be attended with swelling and edema of the larynx and croupy symptoms. In addition, there will be hoarseness of voice, the respiration has a hissing character, the lymphatic glands are not enlarged, the onset is more rapid, albumin [illegible] n[illegible] [illegible]sent.

---

[1] Dublin Journal of Medical Science, J

and the attack does not occur especially at night. The knee-jerks are not altered, the heart is not dilated, and there is no history of infection.

Spasmodic laryngitis is differentiated from diphtheria by its abrupt onset, its occurrence at night, its recurrence, its appearance in more than one member of the same family, the rapidity of recovery, its association with enlarged tonsils or adenoids, its development in children between the ages of 3 and 15 years, and the relief afforded by vomiting.

Laryngismus, on the other hand, is a spasmodic neurosis of early infancy, occurring almost exclusively in rachitic children and unattended with cough. The spasm causes sudden arrest of breathing in expiration, followed by a crowing inspiration. The disorder is most common between the age of 6 months and 3 years. It is unattended with fever, there is no hoarseness, and the child appears to be well in the intervals. Recovery occurs, as a rule, although the spasm may terminate fatally. In addition to its rachitic origin, it may also be of congenital or reflex origin.

THE INFLUENCE OF ALCOHOL UPON SUSCEPTIBILITY TO INFECTION.

It is not long ago that alcohol enjoyed a wide range of therapeutic usefulness. It was given to reduce fever and it was taken to produce warmth; it was prescribed for sleeplessness as well as for the purpose of arousing the flagging mental activities; it was supposed to stimulate the appetite and to furnish food, and it was used accordingly; and in the treatment of infections and certain intoxications, acute as well as chronic, alcohol has long played a very prominent part. In not a few instances the treatment of infections with alcohol in its various forms has been carried to such an extent that "heroic" is the most popular term to describe the doses given.

But the rôle of alcohol as a panacea is being rapidly curtailed. The light of exact investigation has shown that the therapeutic value of alcohol rests on an insecure basis, and it is constantly being made clearer that after all alcohol is a sort of poison to be handled with the same care and circumspection as other agents capable of producing noxious and deadly effect upon the organism. In reality, practically nothing is known concerning the influence of alcohol on the susceptibility and the course of infections in man. Clinical observation can not solve such questions properly. The basis for final judgment must be found in experiments, but so far little has been done in this line. It has been shown by Abbott[1] and others that alcoholic animals are more susceptible to infections with various organisms than normal animals. And Laitinen,[2] after having studied the influence of alcohol upon infections with anthrax bacilli, tubercle bacilli, and diphtheria toxin in dogs, rabbits, guinea-pigs, fowls, and pigeons, reaches the same general results, and this with certainty and directness.

Under all circumstances alcohol causes a marked increase in susceptibility, no matter whether given before or after infection, no matter whether the doses were few and massive, or numerous and small, and no matter whether the infection was acute—anthrax—or chronic—tuberculosis—or more of the nature of an intoxication—diphtheria. The alcoholic animals either die while the controls remain alive, or in case both die, death is earlier in the alcoholic. Without going into details in connection with the experiments—and there is room for further work here—it may be said at this time that the facts brought out by the researches of Abbott, Laitinen, and others do not furnish the slightest support for the use of alcohol in the treatment of infectious diseases in man.

TRADE UNIONISM IN MEDICINE.

An association of physicians is being formed in Detroit on apparently regular trades-union principles, exclusion of all non-members from any professional recognition, "business agents" under the name of ward governors, and all the other essential outfitting of a regular trades union. The Journal is an advocate of organization of the medical profession on legitimate ethical lines, but we trust the report of the proposed action in Detroit is incorrect, at least in some of its details. It is not necessary to imitate the objectionable features of a laborers' or mechanics' organization, nor is it dignified or worthy of a learned profession. If our judgment is correct, and we have no reason to doubt it, the plan as proposed will hardly succeed and will not help the profession as a whole. There is ample opportunity for an organization of physicians that will protect their own interests without sacrificing their self-respect as members of a learned and honorable profession. The proposed plan does not do it, it seems to us, and there are still other features than those mentioned that may be open to objection.

UNGUARDED RHETORIC.

What we must regard as an unfortunate expression in Dr. Jacobi's address at the International Medical Congress[1] has caused some resentment, as will be seen in the correspondence published in this issue, as might perhaps have been anticipated. The speaker undoubtedly referred to certain extreme conditions, but it is unfortunate that he used the terms as applying to any special sections, only partially qualifying his remark by saying that the boundaries of most states include the most various degrees of culture and the contrary. It would have been better had he said all states, for no section of our country has a monopoly of culture or of its opposite. The highest culture and refinement are least obtrusively self-conscious, and of this kind the East has no exclusive supply, any more than has the South of "abject animalism," or the West of any peculiar qualities. Our correspondent may be unduly sensitive, but we ourselves can not but regret the semi-apologetic accent of some portions of the address in regard to our national standing in medicine and science. Foreigners are condescending enough at present, and we naturally prefer such an utterance as that of Osler, who saw in the future of America a scientific Mecca, rather than even an equivocal admission of real or fancied national defects, in such an address. Nevertheless, we do not feel so badly hurt as we might were the implications better based on facts in this special case.

DEATHS AND ACCRETIONS IN THE MEDICAL PROFESSION.

The State Board of Health of Illinois has just published a list of the physicians, licentiates of the Board, whose deaths have been reported since 1877. This gives a total of 2266 deaths, or an annual average of about 100. This is not a large number, considering the fact that there are between 8000 and 9000 licensed physicians in the state, and indeed it is small when account is taken of the large output of new physicians each year. Last spring Chicago institutions alone graduated 676, and Illinois is fairly surrounded on all its borders with medical schools. With the increasing prevalence of state examinations, the tendency will probably be more and more to stiffen the requirements, but it is still difficult to see how all the newly-fledged physicians are to be accommodated with a practice and a living. The chances are that more will be inclined to settle down in their native state or in that in which they have studied and where it might seem to them that any prejudice or allowance in the examinations would be in their favor. With all possible restrictions to entrance in the profession, however, the death-rate among physicians in Illinois is far from being adequate to make room for its share of the annual crop of graduates. Undoubtedly the figures are too low, if anything, and there must also be a large defection from the profession in other ways than death. The figures point clearly to one thing: We are overdoing medical education as regards numbers. This, however, has long been known. The workings of the new medical-practice laws, that are all the while becoming more rigid and general, will be watched with more interest hereafter, and the relative standing of the different colleges before the boards may possibly have a salutary effect in ultimately weeding out some of the poorer ones. At present the evil is in full blast and though the subject is a hackneyed one, it is well to utilize every available fact as a text for the utterance against the modern multiplication of medical colleges with their competition, consequent laxity as to standards, and indigestible output of semi-fitted or unfitted candidates for medical practice.

THE RELATION BETWEEN URIC-ACID EXCRETION AND EPILEPTIC SEIZURES.

The attack of epilepsy may be looked on as a manifestation of the activity of the motor cells of the cerebral cortex, induced by abnormal stimuli. In the absence of positive evidence, there may be reasonable discussion as to the nature of the latter. Sometimes the irritant is grossly mechanical, as a spicule of bone or a clot of blood or a new-growth—hyperplastic or neoplastic—or an inflammatory or traumatic lesion of the brain; at other times it may consist in a poison circulating in the blood. Convulsions due to the influences named are, however, commonly designated epileptiform, in contradistinction from seizures due to less tangible causes, and the latter alone are considered epileptic. The distinction is rather one of convenience than exactitude, and as time goes on, the first group may be expected to expand, while the second grows progressively more restricted. Uric acid is one of the substances that has been thought to be responsible for the occurrence of epileptic seizures, as it has also been held accountable for numerous other derangements of function. Without attributing the epileptic seizure directly to the action of uric acid, it has further been contended, on the basis of experimental observation, that the excretion of uric acid is invariably diminished before each paroxysm of "idiopathic" epilepsy—sometimes immediately before, and at other times at an interval of a day or two; while the excretion is believed to return to and even to rise above the normal, after the paroxysm. The variations in the excretion of uric acid are considered as corresponding to other chemical changes through which the real poison, carbaminic acid, is formed. For the purpose of testing the validity of this proposition, Putnam and Pfaff[1] made a study of 29 specimens of 24-hours' urine from two cases of epilepsy, in the one during a period of three months, with five seizures, and in the other during two periods, each of a month, and each with one attack. The results, however, failed to show that there was any relation between the occurrence of the epileptic attack and the amount of uric acid excreted.

RAPID GROWTH OF THE TUBERCLE BACILLUS.

The tubercle bacillus grows but slowly upon our usual culture-media, a circumstance that causes delay in diagnostic and other investigations. Not long ago, Hesse advanced the claim that by adding a certain nutritive substance, called *Naehrstoff Heyden,* to agar or glycerin-agar, instead of the usual peptone, a medium is presented upon which the bacillus of tuberculosis grows with unexpected rapidity, characteristic growth being evident in two or three days. Indeed, the souring of tuberculous sputum upon this medium was said to be followed by multiplication of the bacilli in six to seven hours, as determined by microscopic examination of the surface inoculated. Hesse, on this account, leans to the opinion that all bacilli thrown off with the sputum have the power of multiplication—a fact of interest and importance if generally corroborated. Ficker[2] and Römer[3] have tested the results reported by Hesse. Both agree with Hesse, that on the medium prepared according to his directions the tubercle bacillus shows greater proliferative energy than on any other artificial subtratum. The exact substance in the *Naehrstoff Heyden* that induces the rapid growth can not be stated as yet. As regards the rapid multiplication of bacilli in sputum placed upon Hesse's medium, Ficker and Römer reach a different conclusion from that of Hesse. In the first place, the impression [illegible] from the surface of the cultures showed that in certain flocculi of the sputum, growth had taken place, whereas in others it was evident that no multiplication had commenced. In the second place, careful study of inoculations of tuberculous sputum upon the usual media showed evidences of increase in the number of the bacilli just about as early as on Hesse's medium. It was also learned that in their growth the bacilli seemed to confine themselves to flocculi of sputum; when the limits of the flocculi were reached, a standstill in the multiplication was noticeable. This observation led to the thought that the mucus in the sputum was the stimulating factor, and Römer found that bacilli inoculated on cultural surfaces with non-tuberculous mucous expectorate carefully washed in sterile water grew much faster than on control plates without mucus. The difficulty in obtaining sterile mucus placed heavy obstacles in the way of extensive investigations along these lines. Enough results have been obtained, however, to show that the tubercle bacillus uses to great advantage the materials present in the mucus surrounding it in the sputum. Mucus alone is not sufficient for growth—and this is perhaps fortunate—because there is no rapid increase in the number of bacilli in tuberculous sputum kept in a moist chamber.

INTERNAL HEMORRHAGIC PACHYMENINGITIS.

The nature of that peculiar form of inflammation of the dura mater, known as pachymeningitis interna hemorrhagica, has long been a subject of discussion and study. But the process or processes are so unique and so different from other inflammations that most questions in regard to this disease still remain unsettled. The description of the microscopic structure of the dura by Key and Retzius twenty-five years ago remains true now. The membrane is composed largely of collagenous fibers mixed with more or less elastic tissue which, according to Melnikow-Raswedenkow,[1] increases in amount with advancing years. According to the recent investigations of this author the external and internal surfaces of the dura are covered with elastic lamellæ or limiting membranes. Upon the internal surface of the inner of these layers we have the epithelial lining of the dura. There are capillary networks near both the limiting membranes. It will be recalled that the external layer is closely applied to the inner surface of the skull and plays the rôle of periosteum for the skull. Melnikow-Raswedenkow examined a number of examples of hemorrhagic pachymeningitis. It begins as an inflammation of the inner or epithelial layer; a superficial exudate forms, capillaries grow into the exudate from the network below the inner elastic layer, and a layer of vascular connective tissue develops. From this a scar may result, but the characteristic feature is the hemorrhagic extravasations from the new capillaries. This process may become chronic, and thick layers of vascular and hemorrhagic or pigmented connective tissue in various stages may form, the oldest parts being nearest the internal elastic layer. It is the advanced forms of this process that give us the clinical picture of internal hemorrhagic pachymeningitis, encountered perhaps oftenest in the insane. The principal point in this sketch of the histogenesis is that the inflammation is the first step, the hemorrhage being secondary and complicating. This corresponds to one of the two current views of the pathogenesis of pachymeningitis; the other view holds that the hemorrhage is the primary event. The earlier stages of pachymeningitis are observed especially in various infectious diseases and do not give rise to recognizable symptoms; undoubtedly the process frequently heals spontaneously; but under some conditions the inner elastic layer grows in thickness and thus the communication between the old capillaries on the outside and the new capillaries on the inside of the elastic layer is greatly hindered, and the organization of the exudate and the return flow are delayed; hence the liability to hemorrhages and to continued inflammation. Great stress is thus laid on the mechanical rôle of the inner elastic layer in addition to the primary toxic agent. The toxic agents give rise to the earliest changes. the inflammatory, which are situated on the surface of the dura; the disease is to be looked on as a complication of general diseases; the peculiar mechanical conditions under which the new-formed vessels engaged in the absorption of the exudate are placed favor circulatory disturbances and extravasations into the new tissue. This view of the genesis of pachymeningitis is ingenious and helpful because it brings into prominence certain etiologic factors as well as the structural peculiarities of the dura.

Medical News.

The University of Athens has founded a chair of hygiene and bacteriology, and appointed Dr. Savas, staff officer in the Greek army, to the place.

The number of persons who graduated last year in the learned professions was 16,448, and of these 5597 were graduates in medicine, 3065 in law, and 1673 in theology.

The Plague in Glasgow.—The recent reports from Glasgow, up to September 5, show that an additional case of plague has been discovered, making a total of thirteen. Three doubtful cases are isolated and 103 are under suspicion and observation.

A Cuban Medical Journal.—Dr. John Guitéras, formerly professor of pathology in the University of Pennsylvania, and who now holds a position in the teaching faculty of the University of Havana, has established a medical journal there, entitled *Revista de Medicina Tropical.*

Food of the Poor in the United States.—As a result of the examination of the comparative nutritive quality of food obtained from nine states and one territory of the United States, Professor W. O. Atwater finds that the American people could get twice as nutritive food for about half the money they now pay. In his opinion three times as much food is wasted as is eaten.

School Hygiene in Germany.—The Minister of Public Instruction for the German empire has ordered that all public schools should be dismissed with a maximum of four hours of consecutive instruction whenever the temperature is 25 C.—77 F.—in the shade at 10 a.m., and that no afternoon session shall be held. The school hours must likewise be shortened even at a lower temperature, if the rooms are small or overcrowded. Children who have an unusually long, unshaded walk to school must be excused from the second session.

---

[1] Ziegler's Beiträge, 1900, xxviii, 226.

A Good Fee.—Dr. J. N. McCormack, Bowling Green, Ky., is to receive the very handsome fee of $10,000 for professional services rendered William Goebel, the murdered governor-elect of Kentucky. At the time the shooting took place, Dr. McCormack, an old friend of Goebel, happened to be in Frankfort, and the wounded man asked that he be called. It was important that the patient be kept alive until he could be sworn in as governor, and the doctor not only remained with him until this had been done, but until the governor had died. There is no objection made by the family to the fee charged, in fact the amount was suggested by a brother of the deceased, a devisee under the will. Dr. McCormack is well known to the profession, and especially on account of the lead he has taken in the successful fight against quackery in Kentucky. He is secretary of the Kentucky State Board of Health.

Koch's Latest Report on Malaria.—Dr. Koch has concluded his malaria research in German New Guinea, after a six months' stay. His experience included the rainy season and the transition periods in which malarial affections are most prevalent. He claims that they confirm his previous announcements and anticipations that the only practicable and effective method of exterminating malaria is the radical cure of every case. He deems the extinction of the infecting mosquitoes impracticable, and observes that the protection afforded by netting is good as far as it goes, but that no substance applied to the skin to drive away the insects has proved of more than transient benefit, while some are directly injurious to the bearer. It is possible, he adds, that some means may yet be devised to artificially hasten the immunization, which naturally is not attained until after four or five years and many attacks of malarial infection, but at present the prospects in this line are slight. He considers his malaria mission accomplished, and now leaves for Herbertshöhe to study the subject of the spread of malaria in a "safety zone." His latest communication is published in the *Deutsche Med. Woch.* of August 23. No new cases occurred at Stephansort during May and June, and only four relapses, all of quartan fever, which he regards as the mildest but the most obstinate form of malaria.

ARKANSAS.

A sanatorium for the Knights of Pythias is to be established by the order at Hot Springs. Congress has donated five acres of land for a site, and a fund of $500,000 is to be raised for the purpose of erecting, equipping and endowing a suitable building.

CALIFORNIA.

Dr. Thomas E. Cummane, of Santa Paula, has located in Ventura.

Mrs. Phoebe Hearst has given $1000 toward the new free hospital at Berkeley.

The county hospital at Riverside is now almost ready for occupancy. It is located on a triangular plot of ground eleven acres in extent with one side facing Magnolia avenue.

San Jose had a death-rate of 12.04 per thousand for the year 1898-1899 and of 12.12 per thousand for the year 1899-1900. The birth-rate for the same years was 9.06 and 9.64 per thousand respectively.

An emergency hospital is urgently needed in Golden Gate Park, San Francisco. This need has been emphasized by the recent death of a San Francisco teacher near the Cliff House, whose life might have been saved had efficient medical aid been at hand.

A hospital to provide for the needs of sick or injured students at the University of California has been established at Berkeley. The president of the university is honorary president of the association, Dr. F. H. Payne, president, and Dr. J. S. Eaton, secretary. The board of directors in addition contains four physicians and five laymen.

Oakland's annual health report shows the lowest death-rate, with one exception, for eighteen years. During the year, 40 deaths from zymotic diseases occurred; 59 died in 1899 from this cause. The annual death-rate per thousand for July was 12.48. Seven died from pulmonary tuberculosis and 7 from apoplexy. Violence caused 9 deaths, including 3 suicides.

CONNECTICUT.

The investigation of the condition of affairs at the New Haven Hospital, which has been demanded by the New Haven Medical Society, is to be made. The committee appointed for the purpose consists of Gen. Samuel E. Merwin, president of the hospital, Judge Simeon E. Baldwin, Prof. Morris F. Tyler, Eli Whitney, Dr. W. H. Carmalt, Dr. W. G. Daggett and Joseph Porter.

DISTRICT OF COLUMBIA.

Dr. J. F. Kemp, who has been for six months an interne at the Georgetown Hospital, has been appointed acting assistant-surgeon in the army.

Dr. Charles C. Marbury, of Washington, has been appointed police surgeon, vice Dr. J. Ramsay Nevitt, appointed coroner of the district.

The Casualty Hospital, Washington, during the month of July treated 97 emergency cases; 83 surgical operations were performed and 17 patients were placed in the wards. During the same month the Eastern Dispensary reports 279 applications for treatment and 6 surgical operations.

HAWAII.

Typhoid fever is reported to be epidemic at the Kapiolani Home for Girls at Kalihi.

The Honolulu board of health, at its August meeting, was appalled to find 12,000 bills arising from the plague epidemic awaiting its action, with many outlying districts to hear from. Although about $20,000 was left in the fund, it seemed likely that it would be only a drop in the bucket toward payment of these bills.

The mortality among Hawaiians is excessive. The report for July shows that 114 died during that month, 80 males and 34 females; 53 were Hawaiians, 25 Japanese, and 12 Chinese; 28 were under 1 year of age and 15 over 60. The mortality for the month for the last six years is as follows: 1895, 51; 1896, 48; 1897, 59; 1898, 75; 1899, 93, and 1900, 114. The annual death-rate per thousand was 30.74. Consumption was the cause of death in 18 cases and typhoid fever in 17.

ILLINOIS.

Dr. Roy Williams has opened an office for the practice of medicine in Rockford.

Dr. Max F. Clausius, of Barrington, has been appointed acting assistant-surgeon in the army.

Dr. Ethan P. Allen, who has practiced in Stillman Valley for twenty years, has moved to De Kalb.

Dr. Charles E. Crawford, of Rockford, has been re-elected supreme medical examiner of the Sons of St. George.

A new monthly medical journal, the *Southern Illinois Journal of Medicine and Surgery,* has appeared. This newest aspirant for professional favor is published at Metropolis.

Cass County commissioners have elected as physicians for the coming year, Dr. John W. Porter, Virginia; Dr. Howard B. Boone, Chandlerville; Dr. Joseph D. Lyons, Ashland, and others.

The Evanston [illegible] end[illegible] fund [illegible]
creasing. The di[illegible] [illegible]000
scribed already. [illegible]
can be completed [illegible]

structed. A training school for nurses is to be one of the improvements undertaken.

The pure food law is not understood by the public at large. It is intended to protect the buyer against imposition. If he wants to buy oleomargarin for butter, chicory for coffee or dilute acid for vinegar he is at liberty so to do, but the law requires that such articles shall be labeled. The *Chicago Chronicle*, in a concise and timely editorial, commends the work of the Illinois Pure Food Commission and shows what it is endeavoring to accomplish.

Chicago.

Dr. Nicholas Senn has returned from his summer vacation, most of which was spent in Texas and Colorado.

Dr. Thomas Warloe has decided to remain in Trondligen, Norway, give up the practice of medicine and go into business.

The Trinity Diet Kitchen for infants at 3213 Wallace street during the last two months has cared for 700 babies, with only one death.

Dr. J. B. Murphy has severed his connection with the College of Physicians and Surgeons—medical department University of Illinois—and has accepted the position of professor of surgery in the Chicago Medical College—medical department Northwestern University. At the same time he assumes the position of chief surgeon to Mercy and Wesley Hospitals.

INDIANA.

Dr. Samuel L. Kilmer, of South Bend, whose eye became infected by sputum from a diphtheric child, is seriously ill and is reported as likely to lose the affected eye.

Two Logansport physicians, Dwight C. Powell and Harry C. Gemmill, Jr., recently appointed acting assistant-surgeons in the army, have started for China via San Francisco.

South Bend must care for its own diphtheria, says Dr. J. N. Hurty, secretary of the state board of health. He has informed the local authorities that they should be fully conversant with their duties and should be able to handle the situation. His duty is to go to places where officials do not understand how to attend to these matters.

IOWA.

A new pest-house is to be provided for Des Moines, as the detention hospital is too near the heart of the city to satisfy the citizens or the city council.

Dr. James R. Wedel, of Vincennes, was accidentally but dangerously wounded on August 13 by a pitchfork thrown from a straw-stack by a farm-hand.

Titusville is to have a hospital costing $14,500. The board of directors of the hospital association has made a contract for the erection of a pressed-brick building two and one-half stories high, 90x47 feet, to be completed and ready for occupancy in six months.

KANSAS.

SMALLPOX STATISTICS.

Dr. W. B. Swan, of the State Board of Health, reports that there are fifteen cases of smallpox at present in Kansas; eleven in Crawford and Cherokee counties, two in the southern portion of Sumner county and two in Topeka. Most of the cases from southern Kansas are among the miners in Crawford county. The eleven cases from Crawford and Cherokee have been reported within the past two weeks. Prompt measures will be taken to stamp out the disease so far as lies in the power of the board. The state law provides that the county commissioners of the several counties shall act as local boards of health for their respective counties. Each local board thus created shall elect a physician, preference being given to an adept in sanitary science, who shall be ex-officio a member of the local board, and the health officer of the same. The county commissioners of Crawford county have been urged to take up the matter of smallpox at once and adopt vigorous measures to stamp it out. The epidemic began last December. Most all, if not all, the county health officers were puzzled as to the origin and nature of the disease and very few cases were reported to the state board of health in that month. The record from the first of the present year is as follows: January, 29 cases, 1 death; February, 437 cases, 10 deaths; March, 456 cases, 5 deaths; April, 370 cases, 1 death; May, 116 cases; 8 deaths; June, 37 cases, 1 death; July, 5 cases and no death.

KENTUCKY.

Dr. Henry E. Tuley, Louisville, returned from his vacation, September 7.

Dr. Thornton Perkins, of Elkton, a graduate of Bellevue Hospital Medical College, has been appointed acting assistant-surgeon in the army.

Suit against the Louisville and Nashville Railroad has been entered by Dr. Dudley S. Reynolds, of Louisville. He claims $10,000 damages for permanent injuries received at Glasgow junction, by the falling of a piece of coal.

MAINE.

Two Biddeford physicians, Dr. John S. Fogg, who has recently resigned after two years' service in the army, and Dr. F. S. Warren, have gone to Europe for a short trip.

MARYLAND.

Dr. Alvin H. Price, of Baltimore county, had a second stroke of paralysis on August 27.

An effort is being made to build a hospital at Annapolis. Numerous accidents occur there, and large numbers of strangers go there for business or pleasure. Dr. William S. Welch is in charge of the project.

Baltimore.

Dr. James Bosley, health commissioner, has been spending his vacation at Rehoboth Beach, New Jersey.

A negro suffering with confluent smallpox was found in a local hospital August 29 and removed by order of the health department to the quarantine hospital. He stated that he had left Elkins, Va., nine days before. The crew of the vessel on which he came were at once vaccinated, but the passengers had disappeared.

Preparations for the coming session are being made at the Baltimore Medical College. The pit of the amphitheater has been enlarged, a new sexagonal tile floor has been laid, new operating tables and new basins have been provided. The operating-rooms have been renovated and a room has been provided for use as a surgical dressing closet.

For the week ending August 26 there were seven deaths attributed to sunstroke, and 76 of children under 5 years of age. Among the deaths were: Cholera infantum, 39; consumption, 24; typhoid fever, 8; consumption, 24; typhoid fever, 8; pneumonia, 7; and drowning, 5. The death-rate for whites was 17.30; for colored, 30 per thousand.

August, 1900, goes down as the hottest month on record here. The daily average was 89.30 F. There were more than 30 heat prostrations, and many more deaths indirectly due to the heat. For 17 days the thermometer reached 90 or over, and for the six days, August 7 to 12, the average was 99.3. The excessive humidity, the unusual dryness and the absence of winds have made it a season never to be forgotten by Baltimoreans.

The health commissioner is not satisfied with the reports of births sent in to his department by physicians, parents and midwives. It is so incomplete as to be of little value. The matter is of such pressing importance, especially in its legal relations, that he proposes this fall to have an ordinance introduced into the city council prescribing a penalty for failure to report births. At present the reports show a greater number of deaths than births.

MASSACHUSETTS.

Dr. A. C. Doten, of Worcester, has been appointed ambulance surgeon to succeed Dr. Francis Shaw, resigned.

Dr. Arthur Fournier has removed from Three Rivers to Gardner, and has taken the office and practice of Dr. J. N. Roy.

Charlton celebrated on August 19, the 81st birthday anniversary of Dr. William T. G. Morton, the discoverer of ether.

Dr. C. A. Sturtevant, West Somerville, has been appointed acting-assistant-surgeon in the army and is already on his way to San Francisco.

Dr. Luke B. Peck, Brookline, has been appointed acting assistant-surgeon in the army and assigned to duty with the United States forces in the Orient.

Union Hospital at Lynn has secured its charter. The incorporators and first board of directors are: Dr. Frank L. Judkins, president; Dr. Charles E. Jenkins, treasurer, and the remainder, physicians from recognized schools of medicine. The hospital will have an immediate capacity of 20 to 30 beds.

MICHIGAN.

The matron of the Jackson City Hospital, Mrs. Flora A. Stickle, who has held that position for eleven years, has resigned, and Miss Minnie West, of Grace Hospital, Detroit, has been appointed her successor.

Dr. John L. Burkart, late city physician of Grand Rapids, and assistant-surgeon of the 32d Michigan infantry, U. S. V. during the Spanish-American war, has been appointed acting assistant-surgeon in the army, and has been ordered to China.

The health officer of Kalamazoo reports that the health of the city is menaced by the unclean vaults, many of which have not been cleaned for more than ten years; by the drive-wells, many of which are close to these unclean vaults, and by the poverty of provision for the health department. He recommends that the city fit up a laboratory at an initial cost of about $500, and that it also erect a garbage crematory.

A free hospital with a well-equipped laboratory is urgently needed for the care of the sick poor of Detroit. Dr. W. F. Metcalf claims that at present the poor of the city are not taken care of in the best way, speaking from a medical standpoint. Their cases are not studied and tabulated as they should be to secure the best results to the patients themselves and to the progress of scientific medicine.

MINNESOTA.

Dr. and Mrs. T. W. Villiers Appleby have returned to St. Paul from an extended tour in Europe.

Dr. Reynaldo J. Fitzgerald, of Minneapolis, who served as surgeon of the 13th Minnesota Infantry, U. S. V., in the Philippine campaign, is seriously ill with appendicitis.

The Postmaster-General has confirmed the appointment of Dr. Walter R. Ramsey as official physician to the post-office department in St. Paul, to take effect September 1.

The State Board of Defectives has decided upon plans for the cottage to be built at the state farm for the use of epileptic boys. The building will cost about $14,000, and will accommodate thirty-five patients.

Smallpox, during the present epidemic in Minnesota, has occurred in 114 different localities in 48 counties and now exists in 32 localities in 16 counties. Up to July 1, 1900, there had been 1164 cases, with 28 deaths.

The Lumberman's Hospital, Brainerd, has been sold by Dr. James L. Camp to the Benedictine Sisters, of Duluth, for $9000. The transfer includes twenty acres of land and the hospital, which will be remodeled by the new owners.

The State Board of Health has sent a circular to presidents of school boards and school superintendents and principals throughout the state urging that especial precautions be taken to prevent infectious diseases at the opening of the school year. To this end it recommends that a salaried inspector be selected by each school board, who should make a daily inspection of schools and pupils, and take all necessary steps to prevent the spread of disease.

MISSOURI.

St. Louis has $258,000 in hand and will proceed at once with the erection of a city hospital to accommodate about 300 patients. The bill passed by the city council August 7 was signed by the mayor August 15 and became a law August 25.

NEBRASKA.

Dr. John M. Neely, of Elmwood, has been appointed local surgeon for the Missouri Pacific railroad.

Dr. Frederick J. Wearne, of Omaha, county physician of Douglas County, has been given opportunity by the county commissioners to resign so that his place may be filled by a new man. No charges are made against Dr. Wearne, but the commissioners desire "to pass the honors around." It is claimed that this is outside of politics, but it "hath an aged and fish-like smell."

NEW JERSEY.

An epidemic of typhoid fever threatens the town of Trevorton, owing to polluted water and defective drainage. Two persons have died and several are now ill with the disease.

The Camden Commission of Public Instruction has decided that persons wishing positions as teachers in the public schools must be healthy and applicants must show certificates from reputable physicians as proof that they are free from tuberculosis, before receiving appointments.

NEW YORK.

Dr. George B. Broad, of Syracuse, is dangerously ill, as a result of infection.

Resolutions of respect regarding the late Dr. John F. Burns, of Long Island City, were passed by the Long Island City Medical Society August 19.

Parks Hospital, Glens Falls, has now an attending staff, consisting of Drs. R. Jerome Eddy, Howard S. Paine, William J. Hunt, David J. Fitzgerald, Fred G. Fielding, Thomas I. Henning, Charles S. McLaughlin, Claude A. Horton and others.

Promotions are in order at the State Hospital, Binghamton. Dr. W. A. White becomes first assistant physician, and Drs. H. Wardner Eggleston, Cecil McCoy and Edward Gillespie are each advanced a step, while Dr. Irving L. Walker, Waverly, recently graduated from the College of Physicians and Surgeons, New York, has been appointed medical interne.

The lay press chronicles the wonder of medical men over a patient in Copenhagen who has been operated on fifty times and has had 2918½ pounds of fluid taken from her body. This reminds one of the epitaph on Dame Mary Page in Bunhill Fields burying-ground, who "in 66 months was tapped 67 times, and had taken from her 496 gallons of water without ever repining at her case or ever fearing the operation."

New York City.

Dr. Henry Koplik has returned from his vacation trip to Europe.

Fast riding on automobiles is not allowed even physicians on emergency calls. Dr. Wallace C. Clark, 113 West 34th street, was fined $3 and costs for this offense.

OHIO.

Dr. Agnes Gardner, of Toledo, has been appointed assistant physician at the Northwestern Ohio Hospital for the Insane in that city.

OREGON.

Twelve out of sixteen physicians who were examined by the Oregon State Board of Medical Examiners were granted licenses to practice. The board held its annual meeting and election of officers, which latter resolved itself into a reelection of officers.

PENNSYLVANIA.

Dr. William B. Ulrich, of Chester, has resigned his position as chief surgeon of the Pennsylvania Military College. He recently celebrated his golden anniversary as a practitioner of medicine.

Philadelphia.

Dr. Albert Woldert has gone to the Pocono Mountains for a short vacation.

The will of Dr. John H. W. Chestnut, recently deceased, bequeaths the sum of $3000 to the Presbyterian Home for Widows and Single Women.

The new morgue has been completed and will be turned over to the city within the next few days. Arrangements have been made at this building so that the funerals may be as private as possible.

THROUGH THE BEQUEST of Edward T. Parker, the erection of a hospital has begun, to be known as the Parker Infirmary, which will be an addition to the Home for the Aged and Infirmed Colored Persons. It is to be three stories in height, will be finished in oak and will contain all the modern hospital appliances. The cost of the building will be about $13,000.

DR. D. BRADEN KYLE, who has just recently returned from abroad, was tendered a complimentary dinner at the University Club on the evening of August 29 by numerous friends. Those present were Drs. A. B. Kirkpatrick, William H. King, Justus Sinexon, C. C. Royce, Carle Lee Felt, Thomas W. Tait, T. D. Taggart, William Corson, E. L. Meyers, Leon Van Horn, and George Doyle.

MR. J. LEWIS GOOD, Chief of the Bureau of Health, announces that the city has never had a cleaner bill of health, so far as contagious diseases are concerned. For several successive days there were no admissions to the municipal hospital. There are, as a rule, between 200 and 300 patients, but at this time there are only 131. He considers this state of affairs as due in part to the energy of the health inspectors.

THE NUMBER of deaths for the week ending September 1 was 413, an increase of 41 over last week, and an increase of 77 over the corresponding period of last year. The principal causes of death were: Apoplexy, 11; nephritis, 26; cancer, 17; cholera infantum, 42; tuberculosis, 49; diabetes, 5; heart disease, 34; pneumonia, 19; marasmus, 24; septicemia, 3; suicide, 2. Contagious diseases were reported as follows: Diphtheria, 61 cases, 13 deaths; scarlet fever, 20 cases, 3 deaths; typhoid fever, 60 cases, 8 deaths.

SOUTH CAROLINA.

CISTERNS, tanks and water receptacles must now be placed above ground by a decree of the city council of Charleston. It is contended that the soil is contaminated and that the water in underground cisterns is easily pollutable. The vote of the council was almost unanimous.

TENNESSEE.

DR. EDWIN WILLIAMS was appointed by the Memphis city council, at a recent meeting of that body, to the position of chief sanitary officer of the Memphis board of health, vice Dr. J. L. Andrews, resigned.

SEVERAL CASES of smallpox have been sent into Memphis recently from Mississippi. The Memphis board of health sent its secretary, Dr. Haase, to Jackson, Miss., to confer with the state authorities with a view to preventing this practice, but no relief could be offered other than general vaccination.

TUBERCULOUS CATTLE have been shipped by a Memphis dairyman into Louisiana, and the health authorities of the latter state have been notified accordingly. Thirty-six cows were quarantined on the farm of the dairyman as tuberculous suspects, autopsies made on five of this herd showing tuberculous lungs. The milk from these cows was found also to be literally alive with tubercle bacilli, and injections of tuberculin gave the customary reaction. The cattle were condemned by the city and county boards of health, and were shipped by the dairyman during the night to New Orleans in order to prevent the loss of his herd.

VERMONT.

THE RESIGNATION of Dr. A. P. Grinnell, of Burlington, from the chair of practice of medicine in the medical department of the University of Vermont, after twenty-five years of faithful service, was accepted, after he had declined to consider the emeritus professorship.

WISCONSIN.

"DR." O. L. ELLIS, of Clark County, the proud possessor of a diploma from the "Independent Medical College," of Chicago, has been fined $25 and costs at Tomah for practicing medicine without a license, and in default of payment now languishes in jail.

THE COMMITTEE on county hospital for Milwaukee has recommended the erection of a new building to cost $60,000, the remodeling of the old building to bring it up to the requirements of modern medicine, and that an isolation cottage be constructed.

CANADA.

THE WESTERN MEDICAL COLLEGE at London has been obliged to provide new buildings, owing to the increase in the number of its students.

A HOSPITAL is expected to be built in White Horse, Yukon, and in operation before cold weather sets in. Of the $2500 required to build and equip the hospital, about $800 was subscribed on the first appeal and the rest is in sight.

CANADIAN MEDICAL ASSOCIATION.

The profession throughout Canada has just received the provisional programs of the coming meeting of this association in the city of Ottawa on the 12th inst. Together with these has also been sent each member of the association a neat brochure containing the constitution, by-laws and ethics of the Canadian Medical Association, with a supplementary history of the respective officers of the association since its inception in the first year of the confederation, in 1867. A perusal of the program shows that many eminent men in the profession in Canada and the United States are to be present and take part in the proceedings, among others being Professor Shattuck, of Harvard, who is to deliver the address in medicine; Nicholas Senn and Webster, of Chicago; Gerster and Allan McLane Hamilton, of New York; Gairdner, of Montreal, and McPhedran, of Toronto. The address in surgery will be delivered at 8:30 p.m. the first day by Mr. Edmund Owen, the distinguished surgeon of London, England. On the evening of the second day the distinguished visitors and the members of the profession throughout the Dominion will be banqueted at the Russell House by the profession of the city of Ottawa. Dr. R. W. Powell, the president, and Dr. W. H. Klock, the local secretary, have all the arrangements well in hand and it is expected that the 1900 meeting will eclipse all previous gatherings. The premier, Sir Wilfred Laurier, will deliver an address of welcome on behalf of the Dominion, and Sir Charles Tupper, the leader of the opposition in the House of Commons, is also expected to be present and deliver an address. During the first three years of the association's existence Sir Charles was its executive head. Intimation has already been received by the local committee that every province of the Dominion will be fully represented, and Toronto and Western Ontario promise to send down a large delegation.

CONCERNING TORONTO'S WATER-SUPPLY.

During the hot wave the taste of the city water became very unpalatable and numerous were the complaints from the citizens of the quality of the water-supply and the temperature thereof, which had reached to 66 degrees. Consequently the medical health officer requested Professor Shuttleworth to make an analysis of the city drinking water. It is certainly gratifying to learn from this report that there need be no apprehension of an outbreak of typhoid, as Professor Shuttleworth reports that the quality of the water is first-class, and from a bacteriological standpoint is excellent. During the month of July the average number of colonies per cubic centimeter was 128, which compares favorably with that of previous years.

WILL THE PLAGUE REACH CANADA?

Since the report of the outbreak of the plague in Glasgow, this is a question which is uppermost in the minds of many Canadians. The secretary of the Ontario board of health has been interviewed in the matter and has given his opinion on the subject. Whilst Dr. Bryce is of the opinion that the disease may possibly invade some of the coast cities of the United States, the danger to the Canadian Atlantic ports is not so great, as being essentially a wharf disease, it spreads with fearful rapidity in the closely-populated dock districts of great cities. Toronto, without slums and with plenty of open spaces, would not afford a good foothold for the plague, but Montreal, with its closely-built districts, is not so favorably situated, and if the disease should once pass the quarantine station and reach Montreal it might be serious. He considers, however, that Canada's greatest danger lies in the Chinese quarters in the British Columbia cities, where they have four thousand Chinese within a few blocks.

SICK AND WOUNDED IN WAR.

Surgeon-Major William Nattress, of Toronto, has just published in pamphlet form a lecture delivered by him last March before the Canadian Military Institute of this city. It appears at an opportune time, when the country has such vital interests at stake in the South African campaign. In the introductory remarks, Dr. Nattress deals with the sentiment of the fifteenth and the early part of the sixteenth centuries, and then follows a review of the facilities which an army in the field has at the present day for the removal of the sick and wounded. He referred to the practical, though perhaps novel, method by which the military surgeon would utilize the traffic of a great city like Toronto in case an emergency should arise for so doing. Whilst our military surgeons sometimes deplore the absence of ambulance wagons in the service, he views this with less alarm when he sees the numerous and countless milk-wagons and vans.

LONDON LETTER.

COMMISSION OF INQUIRY INTO THE SOUTH AFRICAN HOSPITALS.

The government has appointed a commission of five members: Judge Power, Dr. Church, president of the Royal College of Physicians; Professor Cunningham, of Dublin; Sir D. Richmond, and Mr. Frederick Harrison, to inquire into the arrangements for the care and treatment of the sick and wounded during the South African campaign. At first Mr. Balfour proposed to have only the first three members, but the cry was raised that the medical profession, which it was felt was incriminated by the charges of Mr. Burdett Coutts, should not have a preponderating voice on the commission. The evidence taken in England has disclosed the deadly influence of red tape and the effete prejudices which dominate that stronghold of British conservatism, the War Office. I venture to prophesy that it is here the weak point will be found. The medical staff of the army has done its work manfully and in the face of difficulties and dangers, but it is subject to an obsolete system which discipline absolutely prevents it from criticizing. General Sir H. Brackenbury, director-general of ordnance, said in his evidence that the reserve of hospital equipment at the outbreak of the war was inadequate. Just before the outbreak there was a reserve of only one base hospital of 520 beds, and two stationary hospitals of 110 beds each. The under-secretary for war said that the army medical department had no executive authority, but whatever was required in the field had to be granted by one of four high military officers of the war office: adjutant-general, quartermaster-general, inspector-general of fortifications or director-general of ordnance, and while, speaking generally, all its applications were granted, they were usually referred to the army board! This is a beautiful specimen of the spirit in which the war office treats the medical department of the army. Another defect of the same kind, pointed out by Mr. Watson Cheyne, is that the army medical department is not provided with its own independent transport. Application must be made for wagons and animals in all cases when any movement is to take place, and the result is that frequently such transport is not available, or if available can only be supplied to a limited extent. To be thoroughly efficient in the field the army medical department should have their own transport. They have been urging this on military authorities for some years. Indeed, a great deal of difficulty at Bloemenfontein would have been avoided if the department had marched with its own transport from the Modder River. The field hospital which did the best work in the field was the New South Wales ambulance, which had its own equipment. The fact is, the whole system of the military clique at the war office is and has been to treat the medical department as an inferior caste. The evidence of Mr. Rudyard Kipling on this serious subject was rather amusing. He went to a hospital at Cape Town and asked the physicians if they wanted anything. The reply was: "No, we have everything." He then interrogated the nurses, telling them that he could get anything they required out of the "Absent Minded Beggar Fund." One replied "We want pajamas very badly, but don't bring them to the store-issue department. or they will never come out. Bring them to the back door." In this manner he smuggled 98 pajamas into the hospital. The same thing occurred in two other hospitals. The commission has now sailed for South Africa, where they will continue their inquiry.

SCANDAL AT THE NATIONAL HOSPITAL FOR THE PARALYZED AND EPILEPTIC.

A serious scandal has arisen in connection with the management of the greatest hospital in the world for nervous diseases, The National Hospital for the Paralyzed and Epileptic. For ten years grave differences have existed between the staff and the board of management, which has always refused the very moderate request of the staff for two seats on the board. In all except two of the metropolitan hospitals, having 100 beds or more, the staff is represented on the board. The staff alleges, that various details in the hospital management are unsatisfactory; the diet is insufficient and the nursing staff deficient in numbers. The board appointed a sub-committee to inquire into these charges, and it reported that there was no defect in the hospital management of any importance. It has absolutely refused the request for representation by the staff on the grounds that the conduct of a member of the latter might be questioned and that it would not, therefore, be proper for him to sit in judgment on himself. Matters have now reached an acute stage. The staff declares that further representations to the board are useless and has appealed to the public through the press, demanding an independent inquiry into the hospital management.

TUBERCLE BACILLI IN RAILWAY CARRIAGES.

At the Public Health Congress in Aberdeen, Professor Hamilton read a very remarkable paper on the dangers of spreading disease by vehicles of transport. He remarked that although this country had always been in the van of scientific progress, it had not awakened to the danger of disseminating contagion by dust impurities. It was impossible to say to what extent the spread of influenza, diphtheria and tuberculosis was due to insanitary vehicles. The so-called cleaning of railway carriages only meant the stirring up of disease germs. A number of experiments made with the dust taken from the floors of twelve railway carriages showed that two, which were both smoking carriages, contained tubercle bacilli. To prevent the broadcast dissemination of disease the flooring of railway carriages should be removable, the cushions detachable, and the carriages so constructed that they could be periodically cleaned and disinfected.

MOSQUITOES A CAUSE OF ELEPHANTIASIS.

The second malarial expedition of the Liverpool School of Tropical Medicine has telegraphed from Bonny, in Nigeria, an important discovery, viz., that the filaria which causes elephantiasis, like the malarial organism, is found in the proboscis of the mosquito. The same discovery appears to have been made in England by Dr. Low, of the London School for Tropical Medicine, in mosquitoes brought from Australia.

INOCULATION AGAINST CHOLERA AND TYPHOID FEVER.

A parliamentary paper, recently issued, contains some interesting facts on this question. Anticholeraic inoculations were practiced by Haffkine in Bengal in 1896. According to his statistics, among 654 uninoculated cases there were 71 deaths—10.8 per cent.—whereas in 402 inoculated there were only 12—3 per cent. In the British army in India over 2000 men have been submitted to the antityphoid inoculations devised by Professor Wright, of Netley. Of these only a few—5 or 6—contracted typhoid fever subsequently. Typhoid fever is a matter of serious concern to the government of India The admissions of British soldiers to hospital have risen from 18.5 per 1000 in 1890 to 32.4 in 1897, and the death-rate has increased from 4.9 to 9. The government has come to the conclusion that antityphoid inoculations have been shown to provide an immunity equal to or greater than that obtained by an attack of the disease, and that the operation is not attended with risk. It therefore recommends a more extended trial, which is now being carried out.

Marine Hospital Notes.

The commissioned medical corps of the Marine-Hospital service has been considerably added to during the past two years and now consists of 107 medical officers—1 supervising surgeon-general, 29 surgeons, 21 passed assistant-surgeons, and 56 assistant-surgeons.

A great many inquiries are being received in the office of the Surgeon-General from physicians desiring to take the examination for admission to the medical corps. Twelve completed applications are on file, and the medical profession will be duly advised through the columns of The Journal when the date and place of meeting of the next examining board are determined.

ACCESSO PERNICIOSO BERIBERI IN RIO JANEIRO, BRAZIL.

An interesting report has been received by the Surgeon-General of the Marine-Hospital Service from Acting Assistant-Surgeon W. Havelburg, on duty at the port of Rio Janeiro, Brazil. The report is dated July 16, 1900, and gives a general summary of the mortality in and about the city of Rio Janeiro for the six months ended June 30, 1900. He speaks of the disease "accesso pernicioso," which term is used so frequently in the reports from Spanish-American countries, and states that it is a disease of uncertain classification, which may embrace yellow fever, malaria, sunstroke and others of which there is no diagnosis, the term being used in spite of all criticism by physicians. He states that beriberi was formerly not an important factor in the death-rate of Rio Janeiro, but that during the six months for which report is made there occurred in that city 75 deaths from this disease.

NATIONAL QUARANTINE IN HAWAIIAN ISLANDS.

The quarantine service in the Hawaiian Islands is now under the control of the Marine Hospital service. The island and buildings formerly used as a quarantine station at the port of Honolulu have been turned over to the Marine-Hospital service and are being repaired and remodeled in accordance with modern ideas. Honolulu will ultimately have a complete and extensive quarantine plant. Inspection stations have been established at the parts of Hilo, Kahului and Kihei. The commissioned officers of the Marine-Hospital Service in Hawaii are Surgeon D. A. Carmichael and Assistant-Surgeons J. W. Kerr and John W. Amesse. Congress has appropriated $75,000 for the quarantine service during the present fiscal year.

PRECAUTIONS AGAINST YELLOW FEVER.

On account of the appearance of a few cases of yellow fever at Bocas del Toro, Colombia, one of the fruit ports of Central America, the city of Mobile has declined to receive passengers from any of the Central American fruit ports. The city of New Orleans requires detention of fruit vessels bringing passengers from such ports. This has led to a cessation of all passenger travel by water from the fruit ports of Central America to the southern cities of the United States, and has thereby lessened, in large measure, the danger of introduction of yellow fever to such cities.

STATUS OF BUBONIC PLAGUE AT RIO JANEIRO.

A report received from Acting Assistant-Surgeon W. Havelburg, U. S. Marine-Hospital Service, stationed at Rio Janeiro, Brazil, dated July 24, 1900, states that from July 16 to July 24, inclusive, a period of nine days, there occurred in that city forty-one cases of bubonic plague, with nineteen deaths.

HAFFKINE'S AND YERSIN'S SERA.

The Surgeon-General of the Marine-Hospital Service has received from Surgeon Rosenau a copy of a paper by Dr. A. Calmette, read at the International Congress of Hygiene and Demography, this month, entitled "Prophylaxis of Plague by Preventive Inoculations." In this article the author goes into detail as to the difference between Haffkine's prophylactic and Yersin's antipest serum, dwelling especially on the fact that the Haffkine prophylactic, while giving a larger period of immunity, is not to be used after the patient has been exposed to plague, or in any case in which it is probable that infection has taken place. On the other hand, after the disease has appeared, Yersin's antipest serum is the only efficacious remedy that may be employed, and it may also be used as a preventive, but does not confer so long a period of immunity as the Haffkine prophylactic. However, on account of its safety in all cases, it is recommended especially for use on boats, in lazarettos, hospitals and posts of observation.

MARINE-HOSPITAL SERVICE IN ALASKA.

The Marine-Hospital Service has just established a hospital for the relief of seamen at Dutch Harbor, Alaska, on Unalaska Island, with Assistant-Surgeon Dunlop Moore in charge. Dr. Moore has also been detailed, under executive order, to establish a national quarantine there, and has Assistant-Surgeon Carroll Fox as his assistant. Under the same executive order, Assistant-Surgeon B. H. Earle has been made national quarantine officer for Cape Nome, Alaska, with Assistant-Surgeon Bolivar J. Lloyd as his assistant. The latest report from Cape Nome, Alaska, is contained in the following telegram:

> Nome, Alaska, Aug. 6, 1900, via Port Townsend, 18th.
> Six cases smallpox here in isolation. All convalescent. Systematic inspection last week found 12 cases measles, 18 pneumonia, no typhoid, no smallpox.

QUARANTINE STATION AT HAVANA, CUBA.

The former Spanish quarantine station near the village of Mariel, Cuba, twenty-one miles from Havana, has been transferred by the military authorities to the jurisdiction of the Marine-Hospital Service, and extensive repairs and alterations have been made, with a view to perfecting the efficiency of the station. It is situated on a small, land-locked harbor, capable of admitting deep-draft vessels. There is salt water on two sides of the reservation, while at the rear it is separated from the mainland by a stone wall eight or nine feet in height. The reservation contains eighteen buildings and can accommodate 800 persons. If necessity demanded, this number could be increased to 1500. Modern steam chambers and other disinfecting machinery have recently been shipped to Havana for installation at the Mariel station. A force of attendants is kept constantly at the station, so that vessels may be referred there for disinfection from Havana or other ports of Cuba. This station forms a valuable adjunct to the equipment in the harbor of Havana.

YELLOW FEVER IN CUBA.

Yellow fever has not been widely prevalent in the island of Cuba the present season, but there have been a considerable number of cases in the city of Havana and at Santa Clara. A few cases have occurred at Pinar del Rio. The chief quarantine officer for the island of Cuba, Surgeon A. H. Glennan, has been attached to the staff of the governor-general, and exercises supervision over all of the quarantine stations in the island. A very efficient system of quarantine has been established by Surgeon Glennan and his predecessor, Surgeon H. R. Carter, which undoubtedly has been of great benefit to the island of Cuba, and has also prevented, up to the present time, the introduction of yellow fever from Cuba into the United States. In the harbor of Havana the floating disinfecting steamer *Sanator*, the finest plant of the kind in the world, is anchored. In addition to this, a shore disinfecting plant is in constant use. All baggage leaving Havana for the United States is now disinfected, and all baggage leaving other ports of the island for the southern states is disinfected. A complete floating disinfecting plant is now in use at the port of Santiago and three other plants will soon be completed for use at the ports of Cienfuegos, Matanzas and Nuevitas, respectively. These several plants will be so disposed along the coast of Cuba that it will be convenient to refer infected vessels from any port on the coast to one or the other of the cities where the plants are located. Vessels disinfected in Cuba in accordance with the United States quarantine regulations, and receiving a certificate to that effect from the medical officer of the Marine-Hospital Service, are, upon arrival at ports of the United States, considered as having been under observation during the time which has elapsed at sea since disinfection, provided no illness of suspicious nature has occurred on board, and thus their time of detention at the quarantine stations of the United States is much lessened. This lessening of detention at quarantine stations of the United States has been a great help to commerce, while at the same time affording as great or greater protection to the United States than under the former methods.

PLAGUE IN SAN FRANCISCO.

The summary of the plague situation in San Francisco, to and including August 18, is as follows: On June 14, Surgeon Kinyoun reported that from March 7 till June 2 there had been in San Francisco 11 deaths from plague, in 10 of which the diagnosis was confirmed by bacteriological investigation. There were at that time three cases of plague under observation, one of which he was positive was genuine, and which bacteriological investigation conclusively proved to be genuine. July 7, another fatal case was reported as having been admitted to the city hospital under the diagnosis of typhoid fever. Cultures from these cases have been made by the board of health of San Francisco, the State Board of Health of California, and the quarantine officer of Victoria, B. C. On August 18 one more case was discovered, in which the microscopical examination gave confirmatory results. By this summary it may be seen that there were 9 cases in the months of March, April and May, 4 cases in June, 1 in July, and 2 in August, 16 cases in all. This week's "Public Health Reports" contains a very interesting article entitled "The Haffkine Prophylactic and Anti-Pest Serum, the Haffkine Prophylactic against Plague and a *comparison of its Action with Antiplague Serum*," by P. A. Surgeon H. D. Geddings.

INFECTIOUS GASTROENTERITIS IN CONSTANTINOPLE.

The surgeon-general of the Marine-Hospital Service has received a report from the representative of the service in Constantinople, Dr. Spiridion C. Zavitziano, dated August 6, 1900, in which mention is made of a widespread epidemic of infectious gastroenteritis in that city. The disease is almost exclusively confined to children, and the writer makes the statement that not a single child has escaped the epidemic. Many adults have also been affected. The disease is known generally as "cholera nostras." During the month of May eleven deaths occurred from this disease, and during June, ninety-nine. Fifty-six deaths occurred from July 1 to 15. The cases treated by Dr. Zavitviano included about sixty foundlings, and no death occurred among them. The treatment was confined exclusively to the giving of cold baths, as many as twelve a day. In consequence of this treatment, the diarrhea is said to stop in ninety cases out of a hundred, without medication.

PLAGUE SITUATION IN GLASGOW, SCOTLAND.

On receipt of the first rumor concerning plague in Glasgow, orders were issued by the surgeon-general of the Marine-Hospital Service to P. A. Surgeon A. R. Thomas, on duty in London, England, to investigate the rumor and report. Dr. Thomas immediately proceeded to Glasgow and cabled, under date of August 30, 1900, that there had been one suspicious death and several suspicious cases in Glasgow; that the bacteriological examination had not yet been completed; that all contacts had been disinfected and were under medical observation, and that the disease existed in the crowded tenement district. The source had not been traced. On the following day another telegram was received, stating that the local board of health had declared that Glasgow was infected with plague, there having been eleven cases and one suspicious case. Dr. Thomas has been detailed for duty in the office of the U. S. Consul at Glasgow, to inspect the shipping leaving that port for the United States and to issue bills of health in conjunction with the consul. Acting Asst.-Surgeon Hough has been ordered from London to Glasgow to assist Dr. Thomas, and Asst.-Surgeon John F. Anderson has been ordered from Vienna, Austria, to London to assume Dr. Thomas's duties during his absence. At present (September 4) there are reported to be ninety-two persons in Glasgow, either sick with plague or suspected and isolated.

Influence of Menstruation on Gastric Functions. Elsner has been investigating the influence of menstruation on the functions of the stomach and finds that, while the motility is not affected, the chemistry varies from deficient to excessive acidity in many cases. In only five out of the fourteen cases examined were the gastric functions the same during menstruation as at other times. He concludes his communication in [illegible] *Arch. f. Verd. V*, 4, by calling attention to the possible sources of error in investigating the chemical functions of the stomach during the menstrual period.

Correspondence.

Why Do the Quack and the Faith Curist at Times Succeed.

CLEVELAND, Aug. 31, 1900.

To the Editor:—An exhaustive answer to the above query is not contemplated, as it would greatly transcend the limits of this note, but it is proposed to draw attention to two very chief factors in the success of the irregular, of the "christian scientist," and of others of the prolific breed of "curists." One of the causes is wholly without the influence of the medical profession, being deep-rooted in the inherited mental processes of all mankind, while the other is entirely within the power of the profession to eliminate.

First, as Ratzel, in his "History of Mankind," well says in speaking of the Chinese: "Superstitious medicine is one of the deepest-seated disorders of the human mind, of which perhaps it will never quite be cured." This ingrained, often subconscious, but almost always alert, substratum of belief in the intervention of supernatural agencies in the cure of disease and in the relief of suffering is honestly inherited from our savage forefathers, who made night hideous with the din that was to drive away the evil spirit which had caused the sickness, and whose barbarous attempts to aid the sufferer frequently contributed to the fatal ending, even as now does the neglect of the "faith" devotee. Until knowledge of the natural phenomena of the human body is much more widely diffused—slightly prior to the millennium—the mass of mankind will have an unreasoning and implicit trust in the efficacy of the occult in healing disease. During the next two eons physicians perforce will continue to exercise charitable sympathy with the foibles of the public in matters of health. The thorough study of the life-processes thus far known to us is already so intricate that large numbers of physicians have but a smattering of it, and really make their diagnoses and administer their drugs in a fashion but little removed from that of the "medicine man" of ancient days. However, this class is steadily being superseded by men trained in true physiology.

In the second place, there is a matter that lies to our hand every day and that tends constantly to add recruits to the clientèle of the "healers" of various descriptions and of incongruous designations. Stress of financial need and thirst for reputation lead some of our younger surgeons and gynecologists, together with a few of the older ones, all too often to recommend an operation for the relief of conditions that might well be cared for otherwise; and sometimes, be it said in sadness, for the promised cure of lesions whose existence is apocryphal. What is the result? The patient feels that the occasion does not warrant the danger and expense of an operation, and so drifts along unaided to finally fall into the hands of a "curist" of some breed, to receive the necessary stimulus to renewed mental, and consequently, bodily vigor. This patient then naturally becomes an opponent to scientific medicine, even though he may subsequently relapse and require the aid of a physician. While this is happening every day, it is unnecessary. Physicians who recommend radical methods before giving a thorough trial to gentler means administered with common sense and along with hearty encouragement to the patient, are heedlessly doing their profession, and so themselves, a very great injustice. We must make a living out of our profession, but if we do it at the expense of exact honesty to our patients, we shall have done very badly by the profession to which we owe our education. Slipshod ways of practicing medicine are responsible for a very great deal of the quackery and voodooism that steadily flourishes in our midst.

In our wrathful characterization of those who prey upon the superstitious gullibility of people who are not very sick, let us not forget that most dramatic scene when it was said: "He that is without sin, let him first cast a stone." If we **persist** in indiscriminately recommending the removal of [illegible] for [illegible] ure of [illegible] in doing ventro- [illegible] ing every case [illegible] belly that [illegible] ents find a temporary relief in the gentler hands of the irregular. All of these operations and radical procedures are of inestimable value in their proper place, but we must have a care to advise them only when the conditions imperatively demand it.

In this no disrespect is intended toward the most progressive branch of modern medicine—surgery. On the contrary, it is not the trained surgeon who is at fault in this matter, but the doctors of medium education and limited experience, whose self-confidence leads them to the belief that they are competent to make a surgical diagnosis and to operate. It is the amateur operator, if the expression is permissible, who is chiefly responsible for an unduly large proportion of the best material of the irregulars. The man of lesser experience has not yet learned, or else forgets, that to a very considerable proportion of the laity the word "operation" is in itself possessed of unknown terrors. This dread of radical procedure, even in cases in which it would very probably be beneficial, often is responsible for the drift of the ill-informed and unfortunate patient into the arms of the irregular. Great care should be exercised in recommending radical measures, especially if the physician or surgeon has not known the patient sufficiently long to have fully obtained his confidence. Especially is this true of the younger man, for in the case of the surgeon of well-established reputation his advice, even to a strange patient, comes freighted with the full power of suggestion, and the recommendation of even extreme methods is received with due respect.

It is hoped that these statements will not be received as an indication of a propensity for fault-finding, for they are meant simply to point out one observed manner in which many of us are furnishing recruits to the army that follows the quack and the faith-curist and the patent-medicine man.

P. Maxwell Foshay, M.D.

Dr. Jacobi's Address and Sectionalism.

Greenville, S. C., Aug. 23, 1900.

To the Editor:—As a Southerner I may be excused for taking exception to an altogether gratuitous comment on the South, which appeared in your issue of August 18 last—this, too, by one whose eminence, not to say years, should have put him beyond the pale of provincialism. I refer to the words of Dr. A. Jacobi, the venerable and, I doubt not, venerated source of much that has contributed to the advancement of our science. On page 427 is the following: "The greatest refinement of the East, the wild naturalism of part of the far West, the abject animalism of part of the South, are covered by the same flag." Now, there is, of course, great refinement in the East; and there is also "abject animalism," and plenty of it, in the South. But anyone who knows both peoples knows it is equally true that there is "abject animalism," and plenty of it, in the East, and "great refinement," and no lack of it, in the South. It is not, then, the actual expression to which the Doctor gave tongue that is objectionable, but the inferential and insinuating quality of his remarks addressed to those good people across the water who know us not, save as existing, and who quite naturally accept the imputations and inferences of an eminent American as authoritative and indisputable. To say the least, it was an unfair advantage for the Doctor to take—to contrast the highest stratum of society in his own section with the lowest in his brother's section, and give the impression to his hearers that that difference constitutes the difference of the two sections—and no one present to deny his insinuations.

It may be that I am doing the learned gentleman an injustice in thus alleging a "no fair" play, but in that event his remarks were the outcome, then, of carelessness, or of ignorance of existing conditions, either of which is reprehensible under the circumstances. J. Wilkinson Jervey, M.D.

Mailing of Sputum.—The Belgian postoffice department has issued an order that all sputa and such substances to be sent by mail for bacteriologic examination must be put up in thick glass bottles, sealed and inclosed in strong wooden or tin boxes, filled with sufficient soft material to absorb the contents if the bottle should be broken. It is also suggested that the nature of the contents should be indicated on the label.

Book Notices.

The Law in Its Relation to Physicians. By Arthur N. Taylor, LL.B., of the New York Bar. Cloth, pp. 550. Price, $2.00. New York: D. Appleton & Co. 1900.

This little volume has appeared largely as separate articles in the *New York Medical Journal*, but in its collected form its publication is a service to the profession. The author takes up the various subjects that interest the physician in their relation to the law and gives in clearly stated, perfectly intelligible form what we must consider the accepted legal views in regard to them without obscuring them by any unnecessary phraseology or technicalities. The subjects of the rights of the physician and the rights of the patient are fully discussed and the general trend of the law is on the whole one that is somewhat comfortable for the physician to appreciate. It is commonly said that human law is the perfection of wisdom; as medical men we often have reason to see applications of it where this statement is practically reversed, but this fact is due largely to the idiocy of judges and especially jurors. In this country it would seem from recent decisions that we are better off than in Great Britain, and this book bears out this view. It is small, convenient, condensed, and in every way handy, and if, as we assume, correct in its legal statements, a very valuable and convenient hand-book for the average practicing physician on its subject.

Forty Years in the Medical Profession. 1858-1898. By John Janvier Black, M.D., member of the College of Physicians of Philadelphia. Cloth, pp. 498. Price, $3.00. Philadelphia: J. B. Lippincott Co. 1900.

This book is a disappointment; it is not exactly what one would suppose it to be from its title. The author starts out as usual with personal history, reminiscences of different prominent physicians he has met in his student life and since, but as the book progresses he covers nearly every subject in medicine, hygiene, etc., that could possibly be brought in. It shows a wide range of knowledge, or reading, and is, on the whole, entertaining and likely to interest the average layman, though, for the reason stated, it will not be so directly edifying to the physician, who should already know a large part of the information the book contains. As might be expected, the author uses the easy narrative style, without special attention to perfect accuracy in minor points, and once in a while his grammar slips. His facts also, though mainly reliable and accurate, suffer somewhat in the same way, as for example when he states that gaultheria procumbens and mitchella repens are identical plants, probably because both are popularly called wintergreen. He gives a large amount of valuable dietetic information and is very full in his remarks in regard to the adulterations and sophistications of wines and alcoholic drinks, but he seems to omit the similar possibility in beer, since he says all lager beer is made of malt. Such inaccuracies as these appear throughout the book and to some extent mar its value. However, it will be found interesting reading and one could pick it up and pass a little time with it without suffering ennui. The information he gives in regard to pomology and kindred subjects will probably be new to many of his professional readers, while the layman will acquire a considerable superficial knowledge of many points in medicine from the perusal of the doctor's book.

A Memoir of Henry Jacob Bigelow, A.M., M.D., LL.D., surgeon of the Massachusetts General Hospital, etc. Price, $4.00. Boston: Little, Brown & Co. 1900.

Surgical Anesthesia, Addresses and Other Papers by Henry Jacob Bigelow, A.M., M.D., LL.D. Price $4.00. Boston: Little, Brown & Co. 1900.

Orthopedic Surgery and Other Medical Papers by Henry Jacob Bigelow, A.M., M.D., LL.D. Price, $4.00. Boston: Little, Brown & Co. 1900.

I. The Mechanism of the Dislocation of the Hip. II. Litholapaxy; or, Rapid Lithotrity With Evacuation, by Henry Jacob Bigelow, A.M., M.D., LL.D. Price, $4.00. Boston: Little, Brown & Co. 1900.

The first of these four books contains a biography of Dr. Bigelow; a memoir by Dr. Oliver Wendell Holmes; a tribute by Dr. Reginald H. Fitz; an account of the memorial meeting of the Massachusetts Medical Society; obituary notices, and various papers eulogistic of the life and work of Dr. Bigelow.

The second contains seventeen papers on anesthesia, published at various times between 1846 and 1876, the initial one being the first public announcement of the discovery of surgical anesthesia, and the one which carried the important news to Europe. Dr. Bigelow was one of the first to recognize the truth and the value of the claim made by Morton, and he was most persistent in bringing these views forward until they were accepted. These papers brought together in one volume make most interesting reading, especially for those who are curious to know how this remarkable discovery was received. In this volume also will be found other papers and addresses of a miscellaneous nature, among them being "Fragments of Medical Science and Art," a scholarly address delivered before the Boylston Medical Society of Harvard University in 1846; "Medical Education in America," being the annual address before the Massachusetts Medical Society, 1871; "Vivisection," a subject on which Dr. Bigelow held views in opposition to those held by a majority of the profession at that time and now, and a short paper, now first published, on "Execution by Hanging."

The third volume contains a reprint of Bigelow's "Orthopedic Surgery," an elaboration of the dissertation which obtained the Boylston prize for 1844, and various other medical and surgical papers on a variety of subjects.

In the fourth is printed the treatise on the "Mechanism of Dislocations and Fractures of the Hip," which has long been out of print. Shorter papers on the same subject are also reproduced. His work on the hip-joint is what first brought Bigelow so prominently before the profession in Europe. It was in this paper that he described the Y-ligament and pointed out the influence it had in determining the position of the femur when the caput femoris is dislocated, and that the relaxation of this ligament is the key to the reduction of the dislocation of the hip by manipulation. This volume also includes all of Bigelow's papers on litholapaxy—rapid lithotrity—the first of which was published in 1878. The new operation for crushing and removing from the bladder a stone, no matter how large, was bitterly assailed for a time, especially in England by Sir Henry Thompson, but it was soon accepted by all, and hailed as one of the greatest advances made in modern surgery.

Each of the four volumes is complete in itself, but all are bound in uniform style and make a fitting memorial to one of the greatest of American surgeons.

A Text-Book of Practical Therapeutics. With Especial Reference to the Application of Remedial Measures to Disease and Their Employment Upon a Rational Basis. By Hobart Amory Hare, M.D., B.S., professor of therapeutics and materia medica in the Jefferson Medical College, of Philadelphia. Eighth edition, enlarged, thoroughly revised and largely re-written. Illustrated with 37 engravings and 3 colored plates. Cloth, pp. 798. Price, $4.00. Philadelphia and New York: Lea Brothers & Co. 1900.

The previous editions of this work have a deserved reputation, and for this as well as many other reasons we need not say much in regard to the present volume; the fact that it has reached its eighth edition within ten years is sufficient evidence of its acceptability. A very large number of new facts have been added and it seems to us to be very full in the latest acquisitions to our knowledge. There is little doubt that it will retain the popularity which it so well deserves.

Transactions of the Kentucky State Medical Society, forty-fifth annual session held at Georgetown, May 9, 10 and 11, 1900. New series, vol. viii. Printed for the society, 1900.

The annual Transactions of the Kentucky State Medical Society, containing the papers, minutes, etc. of the meeting held in Georgetown last May, came to hand so much earlier this year than formerly that we unconsciously looked at the title-page to see if it did not bear the date of 1899. We congratulate the members on the radical change in this regard. The book contains some excellent papers, as it naturally must, since Kentucky is noted for having brilliant men in its medical profession. The society is in a prosperous condition, numerically, its membership exceeding 500. The book is a neatly gotten up volume.

Deaths and Obituaries.

Herbert Park, M.D., aged 23 years, born in Wigan, England, surgeon of the steamship *Granaense*, of the Red Cross line, died at sea on August 11.

Thomas Wall, M.D., late of Frederick County, Virginia, died in Carthage, Mo., August 21, aged 67 years. He was a surgeon in the Confederate Army during the Civil War.

Thomas J. Thorpe, M.D., of St. Louis, died August 11 from the effects of a gunshot wound accidentally received. He was graduated from Barnes Medical College, St. Louis, in 1895.

Eleazar W. Beebe, M.D., died at Elizabeth, Ill., August 25, at the age of 72 years. He was a graduate of Chicago Medical College in the class of 1867. He was a zealous prohibitionist and a prominent reform advocate.

William B. Waterman, M.D., died at his residence in Brooklyn, N. Y., August 20, aged 38 years. He was a graduate of the medical department of New York University in 1887, and on graduation received the Mott medal in anatomy.

George B. Mills, M.D., Pleasantville, Ohio, died at the Grant Hospital, Columbus, August 22, from shock following the removal of a malignant growth involving the entire superior maxilla, at the age of 75 years. He was graduated from Starling Medical College, Columbus, in 1871.

Francis Fenwick Smith, M.D., died in Frederick City, Md., August 26, aged 72 years, after several months' illness. He was graduated from the Jefferson Medical College, Philadelphia in 1854, and practiced at Bladensburg, Prince George's County, Md., from 1854 till 1863, when he moved to Frederick.

Ferdinand E. Chatard, M.D., of Baltimore, died at Atlantic City, N. J., August 27, from paralysis superinduced by heat exhaustion, aged 61 years. He was graduated from the University of Maryland School of Medicine in 1861, and after an interneship at the almshouse, he pursued his studies for three years in Europe.

Robert Alexander Randall, M.D., died at his home, Lewistown, Ill., August 19, from peritonitis, aged 42 years. He was a graduate of Rush Medical College in the class of 1881, and practiced for a time in Lewistown, but preferring a business to a professional life, he acquired an interest in a drug store, and for many years was at its head.

Charles E. Wehrle, M.D., died at the Toledo (Ohio) Hospital, August 21, from typhoid fever, at the age of 26 years. He was graduated from the University of Michigan medical department, Ann Arbor, had received an appointment as acting assistant-surgeon in the army and was awaiting orders to proceed to the Orient when he was taken ill.

David P. Chamberlin, M.D., died at his home in Toledo, Ohio, August 23, at the age of 75 years, from long-standing vesical disease. He was a graduate of the medical department of Western Reserve University, Ohio, in the class of 1847. He commenced practice in Hudson, Mich., but on the outbreak of war went to the front and served until he was invalided in 1863. He moved to Toledo and had since practiced there.

James Henry Robbins, M.D., Hingham, Mass., died suddenly August 22, aged 61 years, from neuralgia of the heart. He was a native of Calais, Me., a graduate of Amherst College in 1862, and of Harvard Medical School in 1867. He settled in Hingham in 1880. He was, in 1887, president of the South Norfolk District Medical Society.

Madison J. Bray, M.D., the Nestor of the medical profession of Vanderburg County, Indiana, died [illegible] ille, A[illegible] 22, aged 89 years. He was [illegible]rn in M[illegible] at Dartmouth [illegible] tution with honors in 1835. He came to Evansville in 1835 and resided there until his death. He was president of the State Medical Society in 1856, for many years a member of the local board of health, and was a charter member of the county medical society. He was for a time surgeon of the Marine Hospital at Evansville, and at the outbreak of war relinquished practice and recruited the Sixtieth Indiana Volunteers, of which he afterward was made surgeon. After two years he was forced to resign on account of ill health. At the close of the war he was appointed surgeon to St. Mary's Hospital, and held this position for several years.

DEATHS ABROAD

Dr. A. Bor, professor at Amiens, France, succumbed to the heat in Paris, August 1.

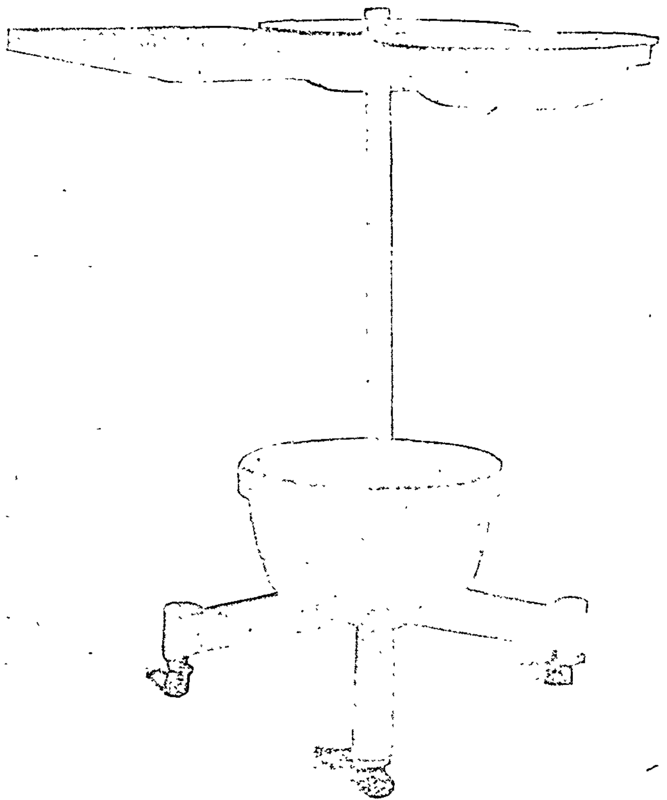
Dr. Paul Lieven, formerly accoucheur to the imperial court of Russia, died recently in his native town, Riga, to which he had retired a year or two ago, after a life of exceptional activity and honor in St. Petersburg.

New Instruments.

Combined Instrument and Sponge Stand and Sterilizing Apparatus.

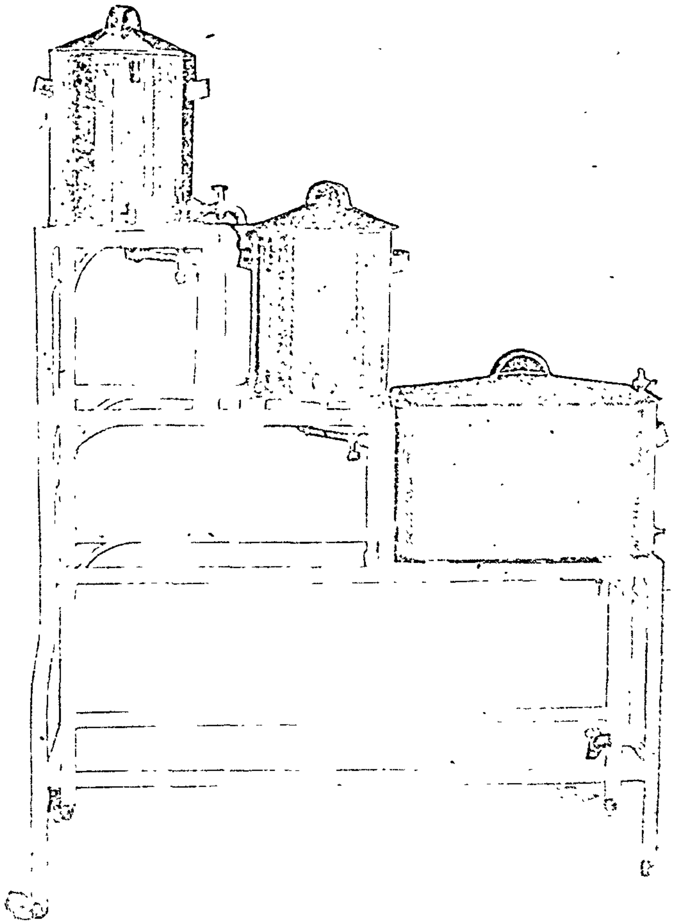
F. F. LAWRENCE, M.D.
COLUMBUS, OHIO.

The accompanying photographs show two satisfactory additions to the operating-room. The first is a combined instrument and sponge-tray stand. It consists of an enameled-iron leaf or table on one side for the instruments, and on the opposite of two rings which support two porcelain basins of large size. One of these is used for small sponges, the other for large ones. At the bottom of the stand is another ring supporting a deep basin, which is also of enameled iron. To the surgeon, who operates with little or no assistance, this table will be of especial advantage; the basin at the bottom is a receptacle for soiled sponges. In my work I handle all instruments, sponges, in fact everything, using no assistant. I place my instruments either in trays on the solid leaf or on a sterilized towel spread over the leaf—the table standing at my right—with the small sponges in the basin nearest me and the large ones in the other. When I have used a sponge, instead of dropping it into the drainage pan or elsewhere, which would make it difficult to count them, I immediately drop it in the deep basin at the bottom of the stand, and when I have finished my operation the count of the sponges is under my direct observation. The stand would be equally useful to the surgeon who operates with an assistant, the only difference being that the stand would be next to the assistant instead of the surgeon. It is the most satisfactory piece of furniture that I have ever used. It occupies but little space and is easily kept sterile.



Instrument and Sponge-Tray Stand.

The sterilizing stand is made of white enameled iron. Two water boilers of five gallons capacity each are made of heavy copper, each boiler being fitted with a water-gauge, which shows at a glance the amount of water in the boiler without uncovering. This gives ten gallons of sterilized water for use on very short notice. Under each boiler is a gas-burner, regularly connected, arranged so that we can use one or both burners at the same time. The sterilizer, which also has a gas-burner for its operating, is the most satisfactory and at the same time the most inexpensive sterilizer that I have used. It consists of a double copper boiler, the outer one larger than the inner, and connected together at the top so as to leave an enclosed space between the outer and inner jackets, of one inch and a half on the sides, ends and bottoms. This also has a water-gauge at one end, which shows the amount of water in the boiler. A valve, to the right and on top of the boiler, is so arranged that when starting the sterilizer it can be opened and a large amount of moisture driven off. Turning the valve half around directs the steam into a tube connected with the inner jacket, which carries it down the end and across the bottom to the center of the sterilizer; hence, it escapes through an opening three quarters of an inch in diameter into the sterilizer and among the dressings. *After sufficient sterilizing* by steam the valve is turned back to first position and opened, permitting the steam to escape and dry out any excess moisture that may have accumulated from the steam. Sterilizing thus gives practically a double sterilization, namely, that by steam and that by dry heat. I have used a sterilizer made upon similar principles to these for a number of years and it has been most satisfactory.



Sterilizing Apparatus.

Forceps for Holding Slides While Preparing Microscopic Specimens.

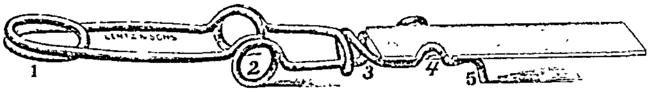
L. NAPOLEON BOSTON, M.D.

Bacteriologist to the Philadelphia Hospital and to the Ayer Clinical Laboratory of the Pennsylvania Hospital; Demonstrator in charge of Clinical Laboratory in the Medico-Chirurgical College.

PHILADELPHIA.

The rapid increase in the microscope's application to scientific study has necessitated that every microscopist collect specimens of all the interesting objects with which he may meet in laboratory work. Furthermore, it is far more satisfactory to preserve the original specimens as a referencee than to depend on notes, which, aside from the time employed in writing and reading, are always unsatisfactory. In the teaching of chemistry, botany, histology, pathology, bacteriology, and clinical microscopy it is necessary that the student prepare a specimen from each subject studied, both as a reference specimen and to demonstrate, beyond a doubt, that he has mastered this art. In board of health laboratories it is necessary to preserve specimen slides as an assurance against criticism, and for this reason most of the bacteriological work is now done by fixing and staining the specimen on the slides.

The leading objection to the staining of specimens on the slide has been that the management of the slide during the preparation of the specimen was difficult, often resulting in the staining of other structures. The need of a forceps to overcome this difficulty has beeen apparent to every laboratory worker, and such a forceps has been in use, by the writer, during the past year.



This forceps is made from a continuous piece of brass wire, which is nickel plated. The accompanying cut will serve to illustrate the forceps, with the slide locked in position. It will be seeen that the wire is so coiled (1) as to form a spring, which serves to hold the slide between the jaws of the forceps. The lateral coils (2) serve a double purpose, in that they are rests for the forceps and provide convenient places for the thumb and index finger during manipulation. The coil (3) at the base of the jaws is simply to hold them in position. The lateral clamp (4) seen on each jaw is provided with a groove so as to accommodate slides of various thicknesses; beyond this point the slide rests on the wire, which is bent (5) so as to support the forceps when the slide is locked in position.

By this forceps, slides are so held as to make their surface level, thus preventing liquid from changing its position when placed on the center of the slide. The forceps is also well adapted for holding the slide while fixing specimens and for staining with heat.

1524 Snyder Avenue.

Sterilized Dressing for Office Use.

D. H. GALLOWAY, M.D.

CHICAGO.

Every physician does at least a little minor surgery, and has in his office a quantity of dressings for this purpose. No matter how careful he may be to keep these dressings clean and antiseptic, they will at times become contaminated by handling and by contact with the outside of the container. This is inevitable if the doctor dresses his cases without the assistance of a trained nurse—as most of us do. Some doctors treat their dressings in a way the description of which would not look well in a medical journal. Surgical dressings should be kept in a box or jar which can be closed air-tight. A cheap container, which I use, is a half-gallon candy jar with a glass top fastened by a metal ring, which screws down upon it; a rubber-ring between cover and jar makes an air-tight joint. In the bottom of this jar under the dressings I keep a small wide-mouth bottle, which is lightly stuffed with absorbent cotton and the cotton is saturated with a 40 per cent. solution of formaldehyde. This keeps the air of the jar continually saturated with the gas and thoroughly sterilizes the contents of the jar between the times of opening for use. No obviously soiled dressings should ever be returned to the jar, but dressings apparently clean may be contaminated sufficiently to infect any clean wound on which they may be used. When the jar is empty I pour a few drops of formaldehyde on the cotton in the bottle and then fill the jar with the sterilized gauze as received from the manufacturer. I am never afraid to use the contents on fresh wounds, though the jar is opened every day for the dressing of all sorts of cases.

Miscellany.

Tuberculosis in Norway.—Dr. Claus Hansen, of Bergen, recently delivered a lecture before the Storthing, at Christiana, on the causes of tuberculosis and the fight against it. He stated that in 1896, 54.5 per cent. of all deaths between 15 and 30 years of age were caused by tuberculosis, and that about 7000 of the inhabitants of Norway die every year of this disease. During the thirty years of his own experience consumption has increased in the Bergen district 80 per cent.

Tuberculosis in Hawaii.—Owing to the alarming increase in the number of cases of tuberculosis in Hawaii, especially among the native Hawaiians and Japanese, the Board of Health of Honolulu is discussing measures directed toward strict quarantine against all tourists who may suffer from this disease. In 1896 the number of deaths from tuberculosis was 48. The number has steadily increased, there being 59 in 1897, 75 in 1898, 93 in 1899, and 114 for 1890.

Havana, Cuba.—Under date of August 14, the report of yellow fever progress during July shows thirty days for the month. The average for the July mortality from 1885 till 1895 reached thirty-four. Last year upward of 25,000 immigrants came to Havana, or thrice the normal number. Non-immunism as a factor, therefore, plays an important part in the calculated gain in the life economy, reducing the mortality in the decade quoted from 4.2 per 1000 to 1.2 per 1000.

Open-Air Marine Treatment for Consumption.—This treatment has been practiced with success for several years in southern Brittany. The Pen-Bron Hospital is used chiefly by working people, the cost of maintenance being provided by the commune from which they are sent. The success of this enterprise has led to the construction of a magnificent private hospital for well-to-do patients, which is built of granite, is near the sea, and is surrounded by pine forests. The hydropathic department comprises hot and cold sea-water baths and sea-weed baths, together with vapor, douche, rain, shower and medicated baths.

Infectious Diseases in Manila.—Major Guy L. Edie, president of the Manila Board of Health, in his report to the Surgeon-General states that smallpox has been prevented from spreading seriously by rigid inspection and vaccination. He proposes to segregate the lepers, who number about 30,000, on one island, where hospitals and other suitable buildings can be erected for their use. Several cases of bubonic plague were diagnosed as typhoid fever, but as soon as the real nature of the disease was discovered active measures were taken for its eradication by a house-to-house canvass made by 100 inspectors, most of whom were Filipino medical students.

Medical Students in Italy.—The total number of students in the faculties of medicine and surgery of the Italian universities during the present academic year (1899-1900) is 6388. They are distributed as follows: Naples, 2009; Turin, 783; Rome, 530; Bologna, 504; Pavia, 496; Genoa, 358; Padua, 309; Palermo, 270; Pisa, 218; Parma, 175; Catania, 167; Modena, 152; Messina, 128; Cagliari, 95; Siena, 81; Sassari, 54. In addition to these, there are three
iver
Camerino, which has 35 medical students,
and Ferrara, with 15. In the faculty of
Institution of Superior Studies at Fl
students.

New Appliance for Closing Wounds.—Bramson, of Copenhagen, exhibited at the International Medical Congress a little appliance which he finds extremely useful as a substitute for sutures in closing wounds. It can be applied in less than half the time and can be opened and the wound inspected at any time. It is merely a row of small trocars set in a small bar on each side of the wound, fastened with eyelets and buttons.

Prognostic Value of Iritis in Syphilis.—Trousseau's experience with forty cases of recurring iritis in syphilitics indicates that this complication renders the prognosis less favorable. The *Semaine Méd.* quotes his communication in the *Ann. d'Oc.* for May to the effect that in only 6 out of the 40 was the course of the syphilis benign. General paralysis appeared later in 3; tabes in 12; cerebral symptoms in 8 and fatal visceral or other severe symptoms not connected with the nervous system in the rest.

Ulcero-Verrucous Endocarditis.—T. Omeltshenko concludes from study of fifteen cases of acute endocarditis that the streptococcus is the chief agent, and that the endocarditis is only a secondary manifestation of the general streptomycosis. All the various types of acute endocarditis that have been described in literature are merely different phases of a single variety—the acute ulcero-verrucous deposits consist always of layers of fibrin and never appear elsewhere than on the ulcerated surface of the endocardium. The most rational treatment is with antistreptococcus serum.—*Russky Ark. Path.*, 3.

Resection of Upper Jaw With Imperceptible Scar.—Severeano exhibited at the International Medical Congress his method of incising the soft parts for extensive resection of the upper maxillary bone with the minimum disfigurement. The linear incision follows the outline of the nose where it joins the cheek, from the root to the median line of the upper lip, which is also incised perpendicularly. From the root of the nose a short horizontal incision is carried to the inner angle of the eye. It is extended inside the lower lid and continued outward on the same horizontal plane 3 cm. from the outer angle of the eye. The flap thus outlined turns back to an astonishing distance, while the line of sutures when it is replaced is comparatively invisible.

The Discoverers of Quinin.—A statue has recently been erected at Paris in honor of the French chemists, Pelletier and Caventou, who discovered quinin. They announced in September, 1820, the discovery of two essential principles in cinchona, to one of which they gave the name of quinin and established its therapeutic value on a scientific basis. It is interesting to note that Farr, of Philadelphia, was able to supply the American public with domestic manufactured quinin before the close of the year. The statue represents the two scientists in the faculty robes, and was erected by the subscriptions of the pharmacists of France. It was unveiled August 7 on the occasion of the International Congress of Pharmacy.

Extrauterine Pregnancy After the Fifth Month.—F. Jayle has observed in twenty-nine cases of tubal or intraligamentous pregnancy that the danger of serious complications diminishes after the first months of ectopic pregnancy. The death of the fetus at the ninth month is seldom followed by accidents. On the contrary, the patients who were not operated on at once, seemed to benefit by the delay, allowing time for retrogression of the placental circulation after the death of the fetus. In one of the instances mentioned in his article in the *Revue de Gyn*, for January-February, the pregnancy occurred in the middle portion of the tube, simulating the position of a normal pregnancy. In another case the nine-months' fetus had been dead six months before operation, but the extensive adhesions proved no obstacle to the total extirpation of the sac.

Papilloma of the Larynx in Children.—Boulay outlines the conduct to be observed, in an article published in *Arch. de Méd. des Enfants*, for May: the papilloma should be removed by the natural route if possible and the attempt should not be abandoned until every known measure has been tried in vain. If the respiration is not seriously affected, expectant treatment is indicated until the child has attained an age when confidence and docility may be anticipated. If there is dyspnea, tracheotomy should be done, a permanent tube inserted, and results awaited. The papilloma may disappear in consequence, but, if not, temporize if at an unsuitable age for operating, but if otherwise, thyrotomy should be done without delay.

Outdoor Life in Rocky Mountain Region for Incipient Tuberculosis.—A correspondent calls attention to the value of outdoor life for incipient pulmonary tuberculosis under such conditions as obtain in the Rocky Mountain region, and suggests that unfortunately a large majority of those who should avail themselves of the climate cure are unable to do so, chiefly for the reason that there is a lack of accommodations adapted to needs of tuberculous patients, and the expense, with no opportunity of self-support. It is true, he says, that there are a number of well-equipped and well-conducted sanitaria on the eastern slope of the Rocky Mountains, but the high rates charged virtually close their doors to the masses. Believing that there is great need of a practical plan by which those affected with beginning tuberculosis might avail themselves of this climate in combating the disease, he offers the following suggestions as a basis for such plan: 1. A system of stations, i. e., small, inexpensive farmhouses, at intervals of ten or fifteen miles, situated along the Rocky Mountain foothills, adapted to their intended use as stopping-places for patients who are to spend most of their time in leisurely and comfortably traveling up and down this system of stations. 2. Provisions of proper food and dietary for patients, chiefly fresh milk, butter, eggs, poultry, vegetables, etc. 3. Development of the plan of self-support for patients, such as gardening, fruit-raising, rabbit and poultry-raising, dairy produce, etc. 4. Development of a system of instruction and inspection that will thoroughly control all sources of infection from patients.

The International Medical Press Congress appointed a committee, consisting of de Maurans, Baudouin and Blondel, to open communication with representative editors, physicians and legislators in all countries to study the matter of literary property from a medical point of view. Baudouin remarked that illustrations can be considered as merely a series of printed characters arranged in a special manner, and consequently can be copied the same as the same area of printed matter, of course citing the name of the author or source. "The interests of science demand the reproduction of the illustrations with the article when required." The Congress devoted a long session to the question of the reproduction of articles and abstracts, formally passing a resolution to the effect that the name of the author, or of the periodical from which the article or abstract is taken, must always be cited. "This will stop the present piracy," Championnière exclaimed. It was particularly emphasized that every journal has the right to send a representative to the meeting of scientific societies and report the proceedings, but no journal has the right to copy the report from another journal, not even from the official bulletin of the society, without citing the source. Another problem pressing for solution is the competition with the journals issued by the manufacturers for free distribution, in which they laud their own wares and which it is to their interest to render as readable and entertaining as possible. In order to react against this condition of affairs the medical press must be established in its true rôle. The medical journal to-day has to contend with many difficulties, the lowering of the subscription price [we note, by the way, that the *Semaine Médicale* and the *Presse Médicale* have each reduced their rates since August 1 from 10 to 8 francs a year] and the increased expense of printing, publishing, editing, etc., but the chief difficulty of all is the transformation of medicopharmaceutic advertising circulars into pretentious, gratuitously distributed journals. The question of exchanges between medical journals was left to the discretion of the interested parties, with the proviso that they are always based on the absolute respect of literary property. The establishment of libraries in large cities where complete files of all the medical journals in the world can be kept for reference was "platonically" endorsed by the Congress, but also left to the discretion of the International Association. Another task entrusted to it is the unification of scientific terms the same for all nations, rejecting, as far as possible, the "proper name" terminology. The introduction of decimal classification of scientific subjects, as already exhibited in the new *Index Medicus*, published in Paris, is advocated by the young International Press Association, and Posner announces that after this year it will be formally introduced into the *Berliner Klinische Wochenschrift*. He observes, in an editorial, that it may at first seem complicated, but in reality it is extremely practical and has already stood the test of time in the libraries of the world. It enables a person of any nationality to grasp at a glance the tenor of the contents of a work. He hails it as an "important advance toward the consummation of a rational system of scientific reporting, which will be comprehensible with equal facility to persons of every land and tongue." The most complete report of the Press Congress we have received to date is in the *Progrès Médical* of August 4 and 11. The International Congress of Medicine has been ably reported in all the chief Paris journals, but the *Bulletin Médical* issued almost daily numbers of over thirty-two pages each, devoted exclusively to the Congress.

The Health of Manila.—An interesting report has been made by Major Guy L. Edie, surgeon U. S. Army, and president of the board of health of the city of Manila, P. I. Besides the several functions belonging to a board of health in supervising all works and conditions affecting the public health, the board has general supervision of charitable institutions, prisons and venereal hospitals and the direct control of the vaccin farm, municipal laboratories, chemical and bacteriological, which the board organized, free dispensaries and hospitals for leprosy, smallpox and bubonic plague. In matters of vital statistics, the board claims accuracy as yet only for its record of mortality. The work of vaccination has made its impress on the mortality from smallpox. For the nine months from October, 1899, till July, 1900, there were 7 deaths from smallpox in the city, while in the month of March, 1899, there were 75 deaths from this disease. The work of vaccination was effected with much difficulty, as the authorities did not consider it advisable to make vaccination compulsory. During the year 622,030 points of vaccin virus were furnished to the army and navy of the United States and to the native inhabitants of the archipelago outside of the city of Manila. In the city and suburbs 114,654 vaccinations were effected. The total number of deaths during the nine months, October, 1899, till June, 1900, inclusive, was 8535, of which 3507 were in children under 5 years of age. The population is variously estimated at from 350,000 to 600,000. During the same period diarrheal diseases caused 1073 deaths; tuberculosis, 992; beri-beri, 642; acute lung diseases, 631; malarial fever, 338; typhoid fever, 41; bubonic plague, 167; leprosy, 46, and smallpox, 7. Besides the 167 deaths recorded from plague a number averaging about 50 per month occurred in the Chinese quarter without medical attendance and unreported, some of which were probably due to plague. Only one death from plague occurred among Americans, and that in the case of a quartermaster's employe. The total number of cases of plague reported was 225, of which only 58 recovered. The opinion formed by Major Edie, from his experience of the past six months, is to the effect that little difficulty will be experienced in controlling the disease in any intelligent community with modern sanitary conditions. The board made early application to the government laboratories in Bombay for Haffkine's vaccin material. Some was obtained from the marine-hospital surgeon, who has also recently received some Yersin serum. It is almost impossible, without the use of force, to use the Haffkine vaccination on Chinese or natives. A thorough test has not been given to either of these materials, but the board has not been favorably impressed with them. Major Edie can not speak in too high terms of the absolute fearlessness, energy and cheerful coöperation of every medical officer associated with him in this work, nor of the faithful and efficient services of the men belonging to the hospital corps of the army on duty with the board.

Societies.

Coming Meetings.

The Canadian Medical Association, Ottawa, Sept. 12-14.

American Association of Obstetricians and Gynecologists, Louisville, Ky., Sept. 18-20.

Medical Society of the State of Pennsylvania, Wilkesbarre, Sept. 18.

Medical Society of the Missouri Valley, Council Bluffs, Ia., Sept. 20.

American Electro-Therapeutic Association, New York City, Sept. 25-27.

American Public Health Association, Indianapolis, Ind., Oct. 22-26.

Idaho State Medical Society, Boise, Oct. 4-5.

Utah State Medical Society, Salt Lake City, Oct. 4-5.

Wyoming State Medical Society, Cheyenne, Oct. 9-10.

Mississippi Valley Medical Association, Asheville, N. C., Oct. 9-11.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, Tenn., Oct. 11-13.

Vermont State Medical Society, Rutland, Oct. 11-12.

New York State Medical Association, New York City, Oct. 16-18.

Medical Society of Virginia, Charlottesville, Oct. 23.

The Association of Hospital Superintendents elected, at their second annual meeting in Pittsburg, Pa., on August 22, the following officers: President, C. H. S. Howell, of Pittsburg; vice-president, Dr. F. E. Baker, of Newark, N. J.; secretary, J. S. Knowles, of Cleveland; treasurer, A. W. Shaw, of Detroit.

Orleans Parish (La.) Medical Society.—At the meeting of this society, August 25, Dr. Louis G. Le Beuf read a paper on "The Medical Diseases of the Kidney." Dr. Edward J. Huhner described an apparatus devised by him for the relief of talipes calcaneus, and Dr. Rudolph Matas reported a case of abdominal aneurysm treated by preliminary abdominal section followed by wiring and electrolysis.

Fourth International Dermatological Congress.—This congress, under the presidency of Dr. E. Besnier, which has been most successful in every way, has just ended. The next congress will be held in Berlin, with Prof. E. Lesser, Berlin, president. Drs. J. Nevins Hyde, Chicago, Henry W. Stelwagon, Philadelphia, and J. Caspar Gilchrist, Baltimore, who were present and read papers, extended to the members, in behalf of the American Dermatological Association, a cordial invitation to hold the next meeting in the United States. It seems, however, that Berlin had a claim for the congress this year, Paris having already had one previously; but at the last congress, held in London, the French representatives requested as a special favor, owing to this being Exposition year, that it be held in Paris. This was conceded, with the distinct understanding that Berlin should have the next. The American representatives, after learning these facts, gave their votes for Berlin. In return for this courtesy it was promised the United States representatives that the congress following that of Berlin should be held in New York.

Rocky Mountain Inter-State Medical Association.—At the second annual meeting of this society, held in Butte, Mont., August 28 and 29. the following papers were read and discussed: G. T. McCullough, Missoula, on "Gastric Fever Affecting Children"; A. M. Holmes, Denver, on "Some Problems Pertaining to Tuberculosis"; H. D. Niles, Salt Lake City, on "Diagnosis of Renal Calculus"; I. B. Perkins, Denver, on "Report of Abdominal Cases"; W. W. Bulette, Pueblo, on "Treatment of Acute Otitis Media"; John O. Polak, Brooklyn, N. Y., on "True Conservatism in the Treatment of Pus in the Pelvis"; J. F. Spellman, Anaconda, "Report of Three Interesting Surgical Cases"; W. W. Grant, Denver, on "Fractures of Elbow-Joint"; W. W. Woodring, Mt. Pleasant, Utah, on "Treatment of Variola"; George H. Barber, Helena, "An Unusual Case of Preputial Calculi"; John A. D

"Shall the Family Physician Do Refractions?"; E. P. Hersey, Denver, on "The Use of Pilocarpin in the Treatment of Inebriety"; I. N. Love, St. Louis, on "Some Points in the Management of Appendicitis, from a Medical Standpoint"; William Treacy, Helena, on "Interstitial Nephritis"; J. N. Hall, Denver, on "An Unusual Epidemic of Chicken-pox"; Hubert Work, Pueblo, on "Chorea Insanies"; S. D. Hopkins, Denver, "Clinical Significance of Tremor"; T. A. Grigg, Butte, on "The Use and Abuse of Glasses"; D. H. Coover, Denver, on "Excision of Upper Cervical Sympathetic Ganglion for the Relief of Simple Glaucoma"; Robert Levy, Denver, on "The Lingual Tonsil"; George W. King, Helena, on "Foreign Bodies in the Esophagus"; George H. Stover, Denver, on "Clinical Appearance of the Blood in Anemias"; A. A. Kerr, Salt Lake City, on "Observations on and Deductions and Generalizations from the Administration of About One Thousand Anesthetics"; E. A. Irwin, Boulder, Mont., on "Practical Points on Feeding the Sick"; C. K. Fleming, Denver, on "Treatment of Retro-Displacements of the Uterus"; T. D. Tuttle, Helena, on "Mastoiditis, When Does It Begin, and When Shall We Operate?"; John O. Polak, Brooklyn, N. Y., on "Infections of the Pelvic Organs in Young Girls"; B. C. Brooke, Helena, on "Double Operation for Undescended Testicle"; Edward Jackson, Denver, on "Principles of Asepsis Applied to Operations on the Eye"; Rudolph Horsky, Helena, on "Malpractice Suits and the X-Ray." Dr. C. K. Cole, Helena, delivered his address as retiring president.

Therapeutics.

For Ulcers.

℞.	Bromol	gr. xv	1
	Vaselini	℥i	32

M. Sig. As a local application. —*Phil. Med. Jour.*

Bromol is obtained by pouring an aqueous solution of bromin in an aqueous solution of phenol; a white, clear precipitate results. The crystals are insoluble in water, but very soluble in alcohol and in fatty and volatile oils.

Painful Menstruation.

℞.	Acetanilidi	gr. iii	18
	Caffeinæ citratæ	gr. ss	03
	Sodii bicarb	gr. iii	18

M. Sig. At one dose. To be repeated in one hour if necessary.

Floeckinger, in the *New Orleans Med. and Surg. Journal*, advises the following in cases of simple colds attended by pains in back and limbs.

℞.	Heroin hydrochlor	gr. 1/12	005
	Salophen	gr. x	66
	Sacch. lactis	gr. iii	18

M. Sig. One powder every two hours.

Wet and Dry Surgical Dressings.

1. A dry dressing is superior to a wet one in incised wounds.
2. In contused and lacerated wounds a wet dressing should be employed for a week or two, followed by a dry one.
3. In carbuncles, boils and infected wounds a wet dressing is indicated.
4. When pus has burrowed and sinuses exist, packing and a dry dressing are preferable.
5. In deep punctured wounds with a small orifice a wet dressing is best.
6. In all wounds of the scalp, whether infected or not we should use a dry dressing.

—R. M. Skillern: *Phil. Med. Journal.*

Creosotal.

Chas. F. Stokes, in the *Brooklyn Med. Journal*, reports seven cases of lobar pneumonia successfully treated by creosotal in conjunction with heart tonics. He noted a rapid fall in temperature following its administration. It was given in capsule, in doses of twelve minims every two hours. Creosotal is prepared from beechwood creosote and not from guaiacol. It is quickly absorbed, and is said to give less disturbance than creosote.

Enlargement of the Prostate Gland.

℞.	Potassii iodidi		
	Extracti hyoscyami āā	gr. ii	12
	Olei theobromæ q. s.		

M. Fiat suppositorium. —*The Prescription.*

Hemorrhoids.

The *Philadelphia Medical Journal* notes the following in treatment of hemorrhoids, by Dr. Boas, in *Centralblatt für Therapie:*

℞.	Chrysarobin	gr. 1/5	072
	Iodoformi	gr. 30/100	02
	Ext. belladonnæ	gr. 15/100	01
	Cacao butter	gr. xxx	2

M. For one suppository. Sig. Two or three may be used daily.

℞.	Ext. hamamelidis fluidi	℥i	32
	Ext. hydrastis fluidi		
	Tinct. benzoini comp. āā	℥ss	16
	Tinct. belladonnæ	ʒi	4
	Ol. olivæ (cum acid carbol five per cent.) q. s. ad	℥iii	96

M. Sig. Apply frequently to the parts. —*Med Bulletin.*

AS AN OINTMENT.

℞.	Chrysarobin	gr 1 1/5	072
	Iodoformi	gr ½	03
	Ext. belladonnæ	gr. 1/6	01
	Vaselini	℥ss	16

M. Sig. As an ointment two or three times daily.

Chrysarobin is a principle obtained from Goa powder, a concretion found in the stems and branches of Andira araroba. It is generally employed in ointment of 10 per cent. strength in treatment of various diseases of the skin. It is a light-yellow crystalline powder, very slightly soluble in water or alcohol but fully soluble in alkalies.

Hydrastis in Dysmenorrhea.

℞.	Tinct. hydrastis		
	Tinct. viburni prun. āā	℥iv	16

M. Sig. Ten drops every two hours, in water.

—*Gazette de Med. et de Chir.*

Gastralgia.

℞.	Chloralis hydratis	gr. iii	20
	Sodii hyposulphitis	gr. vi	40
	Aq. menth. piperitæ	ʒi	4

M. Sig. At one dose. Repeat as required by frequency of attacks, guarding against overuse of chloral.

Facial Neuralgia.

℞.	Butyl chloral hydratis		
	Alcoholis, āā	ʒiiss	10
	Glycerini	ʒv	20
	Aquæ destil.	℥iv	128

M. Sig. Half a soupspoonful to be taken daily.

—*Bocquillon-Limousin.*

Carbuncle.

℞.	Antipyrini	ʒiiiss	14

Ft. chart No. xx. Sig. One powder in water every two hours, or,

℞.	Ammon. carbonatis	ʒiiss	10
	Ext. coffee flu.	℥ss	16
	Syr. simplicis, q. s. ad	℥iv	128

M. Sig. One or two teaspoonsful every two hours.

—Shoemaker.

Acute Follicular Tonsillitis.

℞.	Sodii boratis	ʒiss	6	
	Potassii bromidi	ʒiss	6	
	Acidi carbol	m. xx	1	33
	Glycerini	ʒii	8	
	Infusi althææ q. s. ad	℥iv	128	

M. Sig. Use as a gargle four or five times a day.

—*Jour. de Med. de Paris.*

Acute Pharyngitis (Acute Sore Throat).

℞.	Decoct. althææ fol. (parts 1 to 10)	℥vi	192
	Tinct. opii	m lxxv	5

M. Sig. Use as a gargle four or five times a day.

Apply wet compresses to the neck; give the patient small lumps of ice to hold in the mouth. —*Exchange.*

Powder in Acute Suppurative Otitis.

℞.	Sodii biboratis			
	Sodii bicarb. āā	gr. i		06
	Amyli	gr. i		06
	Pulv. acaciæ	gr. iv		24
	Nosophen, q. s. ad	ʒi	4	

M. Sig. Cleanse thoroughly, then blow some of the powder in the ear. —*Exchange.*

Otorrhea.

℞.	Liq. plumbi subacetatis (Goulard's ext.)	m. xx	1	33
	Acidi acetici diluti	m. vi		36
	Vini opii	m xx	1	33
	Aquæ destil., q.s. ad	℥i	32	

M. Sig. Drop ten drops into the ear three or four times a day, previously warmed. — *N. Y. Med. Jour.*

Acute Orchitis.

℞.	Tinct. aconiti	ʒii	8
	Guaiacoli	℥i	32
	Glycerini	℥iii	96

M. Sig. Paint the scrotum with this solution night and morning and place over it a piece of gauze saturated with the above. Over this a layer of cotton covered by a piece of oil silk and support the testicle.

—V. Buchtel: *Louisville Jour. of Med.*

Lupus Vulgaris.

℞.	Hydrarg. ammoniati	gr. x		66
	Acidi carbolici	m. x		66
	Pulv. camphoræ	gr. x		66
	Ung. zinci oxidi	℥i	32	

M. Ft. unguentum. Sig. Apply locally. —*Med. Bulletin.*

Acute Gastrointestinal Catarrh.

℞.	Creosoti	m. xii		72
	Tinct. opii camphoratæ	ʒiv	16	
	Bismuthi subnitratis	ʒiii	12	
	Pepsinæ scales	ʒi	4	
	Syr. aurantii corticis	m. xxx	2	
	Aq. menth. piperitæ q. s. ad	℥iii	96	

M. Sig. One teaspoonful every two hours for a child of 2 years. Vary with the age and severity of the case.

—*Med. Record.*

Otalgia.

℞.	Quininæ sulphatis	gr. xviii	1	2
	Potassii iodidi..	gr. xxxvi	2	
	Sacchari albi	gr. xlv.	3	

M. Ft. Chart. No. vi. Sig. One twice a day.

IN CHRONIC FORM.

℞.	Zinci oxidi		
	Valerinæ radicis		
	Ext. hyoscyami alc., āā	ʒss	2
	Pulv. ext. glycyrrhizæ, q. s.		

M. Ft. pil. No. 100. Sig. One a day, increase from one a day up to thirty, then decrease. Politzer: *Med. Rec.*

Chronic Prostatitis.

℞.	Ichthyolici	ʒii-ʒv	8-20
	Olei theobromæ	℥iss	48

M. Ft. suppos. No. xxiv. Sig. Insert one suppository into the rectum in the morning after stool and in the evening. If defecation occurs a second time, use another suppository. The symptom of painful defecation, sense of weight and disturbances of micturition will be favorably affected as the prostate decreases in size and induration.

—Frendenburg: *Med. Record.*

Removal of Ear Wax.

℞.	Hydrogeni dioxidi (50 per cent.)	℥iv	128

Sig. Use in syringing out the wax.

In an article in the *Phila. Med. Journal* hydrogen dioxid is recommended in one-half strength as the best solution to use in the ear, causing no irritation after drying well with absorbent cotton.

Carbuncle or Boils.

℞.	Olei olivæ	ʒxv	60
	Plumbi oxidi	ʒiiiss	14
	Olei lavendulæ	ʒi	4

M. Sig. Apply locally as an ointment. —Bulkley.

Liniment in Rheumatism.

℞.	Spts. camphoræ		
	Tinct. opii		
	Spts. ammoniæ, āā	℥ss	16
	Olei olivæ	℥i	32

M. Ft. emulsio. Sig. Apply locally four or five times daily. —*Med. News.*

Liniment for Sprains.

℞.	Ol. terebinthinæ		
	Acidi acetici, āā	℥ii	64
	Ol. lavendulæ	ʒi	4
	Vitelli ovi		
	Aquæ, q. s. ad	Oi	512

M. Sig. Apply two or three times daily. —*Exchange.*

Inflamed Rheumatic Joints.

℞.	Sodii carbonatis	ʒvi	24
	Tinct. opii	℥i	32
	Glycerini	℥ii	64
	Aquæ destil., q. s. ad	℥xii	384

M. Sig. Saturate hot cloths with the lotion and apply to the parts. —Osler: *Penn. Med. Jour.*

Erysipelas.

℞.	Ferri sulphatis	℥i	32
	Aquæ destil.	Oi	512

M. Sig. Apply by compresses and renew every two or three hours. —Valpeau.

Gonorrhea.

℞.	Plumbi acetatis	ʒss	2
	Zinci sulphatis	gr. xvi	1
	Ext. krameriæ fluidi	ʒii	8
	Tinct. opii	℥ss	16
	Aquæ destil., q. s. ad	℥vi	192

M. Sig. Use as an injection two or three times a day.

—Horwitz.

Swollen Feet.

In gouty or rheumatic subjects, non-dropsical in character.

℞.	Tablets acidi arsenosi, āā	gr. 1/40	0015

Sig. One tablet after each meal. —Hare.

Convulsions in Children.

It is recommended that a warm bath or mustard bath be given the child, and to prevent recurrence of convulsions give the following:

℞.	Potassii bromidi			
	Sodii bromidi			
	Ammon. bromidi, āā	gr. viii		50
	Syr. aurantii	℥i	32	
	Aquæ destil., q. s. ad	℥iii	96	

M.. Sig. One to three teaspoonfuls every fifteen or twenty minutes for a child 2 years of age or older.

Epistaxis (Nose Bleed).

Dissolve six ordinary strips of white gelatin in a cup of boiling water and inject 20 to 30 cm. (2/3 to 1 ounce) of the liquid warm solution into the nostril, first compressing the alæ nasi so as to prevent the escape of the liquid, which quickly forms a mass and checks the hemorrhage.

—Experiment of Freudenthal: *Med. Record.*

Parasiticide Ointment.

℞.	Acidi salicylici	gr. xlv	3	
	Sodii boratis	gr. xv	1	
	Balsam peru	gr. xxx	2	
	Ethereal essentiæ anisi	gtt. v.	1	33
	Essentiæ bergamot	gtt. xx	1	33
	Vaselini	ʒvi	24	

M. Ft. unguentum. Sig. Apply to part affected.

—*Exchange.*

Hypodermics Rendered Less Painful.

Dr. Stowall, in *Med. Rev.*, states that hypodermics are rendered less painful and more readily absorbed by dissolving the tablet in a saline solution instead of water alone.

New Method of Treating Syphilis.

Wear a bag containing mercury on the chest, a dram of the metal being poured into the bag each [illegible].

—Bulkley: [illegible] *cd*

Medicolegal.

Opinion to Be Rejected.—When the opinion of a medical expert is based on a hypothetical question, the Supreme Court of Michigan holds, in the case of Dudley vs. Gates, that it is proper to instruct the jury that if the facts, or any of them, are not true, the opinion must be rejected by the jury.

Loss of Left Arm Not a Total Disability.—A contract of insurance with a fraternal insurance company provided for the payment of a certain benefit whenever a member thereof, by reason of disease, accident, or otherwise, became totally and permanently disabled from following his usual or regular business, occupation or profession. A member, who was a pharmacist and engaged in running a drug store, was accidentally shot in the left arm, which was amputated at the shoulder-joint. No other injury was alleged to have been sustained. But the loss of the left arm alone, the Supreme Court of Kansas holds, in an action upon the contract of insurance, case of Smith vs. Supreme Lodge of Order of Select Friends, did not constitute a total disability within the terms and meaning of the contract. It is a matter of common knowledge, the court says, that much, if not all, of the work and business of a druggist can be fairly well done by one who has lost a hand. He will not be able to compound medicines so conveniently and expeditiously as a person who has both hands, but a large proportion of the medicines sold in a drug store to-day, the court understands, are compounded and ready for sale before they reach the hands of the retail dealer. It is equally well known, it thinks, that a large proportion of the business of the ordinary drug store consists in the sale of medical stores and instruments, toilet articles, holiday goods, cigars, soda and mineral waters,; etc. and hence, the court asserts, all know that this, if not all, the work of the druggist may be done, and the business conducted, with reasonable efficiency, by a person who has lost a hand.

Upholds Age of Consent Statute.—The Supreme Court of Minnesota holds, in State vs. Rollins, that the "Age of Consent" statute of Minnesota, which makes it criminal to carnally know and abuse a female child under the age of 16 years, is not void for uncertainty, but a valid penal enactment. But, it was further urged that, besides the objection thus met, there was a fatal conflict with the marriage laws of the state. Not so, however, thinks the court. It holds that this penal statute does not apply to relations between married persons within the ages authorized by law for entering upon the marriage contract. Indeed, it even thinks that the statutes harmonize together quite well; and it boldly asserts that it does not fear that the rigid enforcement of this statute will place seducible boys at the mercy of foolish girls under 16 years of age. It does not consider that the young men are so much in need of restraint as a more mature specimen of masculinity familiarly known as the "masher"—described by it as a parasite upon woman, rather than her support; very crude in his notions of her better qualities, and selfish and cruel in his conquests over inexperienced females who may be misled by his baneful attentions, to their own injury, before they are fully aware of the danger they incur, and descend into that social abyss from which return is very difficult. Moreover, it declares that it sees no violation to language, good sense or common decency to hold that sexual connection with a female under the prohibited age, however slight, constitutes abuse, and, in view of the history of the law, it says that it has no doubt that this was its intent when enacted. So it holds that proof of any act of sexual connection between the female and the party charged with the commission of the offense will sustain a conviction under the statute.

Menstruation too Improbable.—In Howard vs. People, the Supreme Court of Illinois had before it an abortion case wherein, on account of the death of the alleged, unfortunate victim, the prosecution was driven to rely on circumstantial evidence to sustain its charge. There was, for one thing, uncontradicted evidence that for two or three nights prior to the date of the reception of the girl in the house of the accused she was not in her usual health; that she had hemorrhages, which the witness, a female companion. or roommate, presumed to be the result of her menstruation period. Also, evidence that, on the morning she reached said house, as she passed up the stairway to the room assigned her, drops of blood fell from her person on the carpet and matting. Physicians were called to testify on behalf of the accused, who gave opinions to the effect that the miscarriage had taken place prior to these hemorrhages. The prosecution offered the testimony of other physicians, who testified that, although very unusual, women do menstruate during pregnancy, and it semed to be the theory of counsel that the hemorrhages mentioned were explained in this manner. But not so thinks the supreme court. It declares that the extreme improbability of menstruation in the case of a woman from four to four and one-half months in pregnancy, together with the fact that an abortion took place at about that time, refuted, to its mind, the idea of those hemorrhages resulting from natural causes. On the other hand, the court does not consider that it followed, from all the facts and circumstances in proof, that the miscarriage was produced prior to the time the girl went to that house, without any guilty knowledge or agency on the part of the accused. The girl, in all probability, it thinks, had, with or without the counsel of others, attempted to bring about the miscarriage, and the hemorrhages may have resulted from such attempts. So, when all the facts in the case and the theories of the physicians, which, it says, necessarily were only theories or matters of opinion, were carefully weighed, the court holds that it could not be said that the jury was unwarranted in its conclusion that the accused was guilty.

Death from an Overdose of Morphin.—A policy of life insurance contained this clause: "In the event of the death of the insured from suicide, whether sane or insane, within three years from the date hereof, the liability of the company shall be limited to a return of the premiums paid on this policy." Its construction was called for, or rather the question of the company's liability thereunder was raised, in the case of Brown vs. Sun Life Insurance Company, where the insured died from an overdose of morphin. This leads the Court of Chancery Appeals of Tennessee to say, to begin with, that it is a proposition of law, supported by authority as well as reason, that this and similar clauses in policies of insurance, conceding them to be valid, are not infracted by the accidental and mistaken taking of an overdose of medicine or poison or by the unintentional taking of his life by the insured. The principle or rule, in cases of this character, it goes on to state, is equally supported that suicide or intentional destruction by one's own hand is not presumed. The presumption is otherwise. The company interposing the defense of suicide, whether sane or insane, must overcome this presumption, and satisfy the jury or court trying the case, by a preponderance of evidence, that the self-destruction was intentional. Here, there was no evidence that the insured was insane. He was of foreign birth, about 58 years of age, and subject to rheumatic attacks. Less than three hours before his death he called for 12 grains of morphin. Asked by the druggist, who testified that he saw no evidence of derangement at the time, whether he desired it put up in proper doses, he replied that it was not necessary, as he knew how or in what quantity to take it. He had no relatives to benefit by dying, and leaving them to get the proceeds of the policy and his other effects. Nor had he been disappointed in love, or in any scheme of business or money-making. Sometimes, however, when suffering from rheumatism, he drank to excess. Under these circumstances, taking the facts in connection with the legal presumption stated, the court holds that it was proper to find as a fact that the insured did not designedly take an overdose of the drug for the purpose of ending his life, although it thinks that the question of whether he purposely took an overdose of the drug, or innocently, ignorantly or accidentally did so, was about evenly balanced.

***Maintenance of Pest-House Close to School.**—The Court* of Civil Appeals of Texas has approved, in the case of Thompson vs. Kimbrough, of the suppression by injunction of the maintenance of a pest-house, for smallpox suspects and those afflicted with the disease, within 192 feet of a public school, on property purchased by the county. One of the contentions was that the school district trustees had no legal right to maintain a suit for injunction against the county judge, commissioners' court and county health officer. But the court answers that, if the ground of interest alone be considered, it would certainly appear that the trustees had such interest in the premises as would give them standing as complainants against persons attempting to injure the school property and interfere with the operation of the school. Then, it was contended that the law invested the commissioners' court, in connection with the county health officer, with exclusive and final jurisdiction in the matter of establishing and maintaining pest-houses and detention camps to prevent the spread of smallpox and other infectious and contagious diseases, and that the exercise of this jurisdiction was not subject to review by any judicial tribunal. Referring to the Texas statutes on the subject of quarantine, the court says that they authorize cities and counties to establish and maintain quarantine when thought necessary for the preservation of the public health, and require their co-operation with the state authorities in the maintenance of a quarantine proclaimed by the governor of the state. It is also required that the county judge of each county shall appoint, after each general election, a "county physician," who is made the health officer of the county. He is charged with the duty of establishing, maintaining and enforcing local quarantine, when declared by proclamation of the commissioners' court. The commissioners' court is authorized whenever it is believed that they are threatened with the introduction or dissemination of a dangerous, contagious or infectious disease that may be guarded against by quarantine, to establish and maintain detention stations or camps; to provide hospitals, tents or pest-houses for the sick, etc.; and the county is required to meet the expenses. Now, it may, and perhaps should be, admitted, the court goes on to say, that the exercise of the authority of the commissioners' court to proclaim quarantine, and to have it established, maintained and enforced through the county physician, is not subject to review by judicial tribunals. But, the court says, it does not necessarily follow that all of the acts of the officers and agents of the county in relation to the subject-matter are beyond the reach of judicial authority. The authority of the commissioners' court to proclaim and cause the enforcement of quarantine does not carry with it the arbitrary power in the officers and agents of the county to unnecessarily violate the rights of others. The existence of such authority does not imply that the officers and agents of the county may establish and maintain a nuisance, either public or private, not necessary to the end to be accomplished. The establishment of a detention station and pest-house in which to place, respectively, persons who have been exposed to smallpox, and those afflicted with the disease, in such close proximity to a public school that the germs of the disease may, and probably would, be disseminated among the children attending such school, the court holds, furthermore, would be the worst character of nuisance, and would violate the rights of those interested in the school. To uphold such an act, it adds, would not strengthen the county's efforts to prevent the spread of the loathsome and dangerous disease, but it would support the very means of its dissemination, and thereby defeat the humane object which the law designs to be accomplished.

AMERICAN.

1. **Military Surgery.**—Borden analyzes the statistics as to wounds of the neck, trunk and extremities. He thinks the mortality from injuries to the head, face and neck is not reduced since the use of modern missiles, but that the wounds of the abdomen and thorax show a somewhat diminished mortality, though still serious. In the wounds of the extremities the small-caliber bullet shows itself a humane weapon and here the aseptic and antiseptic methods have produced their best results. In his general conclusions he thinks that the small-caliber rifle is not a humane weapon as far as its death-dealing effects are concerned, though it may be so considered as far as the effects of its projectile on those not immediately killed are concerned, and conservative treatment has been a most potent factor in the saving of life and limb. Operations on the field or at field hospitals should be restricted to cases of imperative necessity while the permanent and base hospitals should receive the wounded as soon as possible and have every appliance for their relief. Military surgery does not differ from ordinary surgery excepting in locality and environment and the greater number of special injuries, gunshot wounds, etc.

3. **Psychoses of the Menopause.**—Chapin finds from his study and experience that while the menopause may be a period of stress, it is not properly the cause of insanity excepting in cases with heredity or previous attacks. Women who become insane at this period are as a rule neurotic or have a psychopathic heredity or history. Many approach this period with groundless apprehensions and in this sense it may be somewhat more of a dangerous epoch, but we should discourage these fears as far as possible.

4. **Koplik's Spots.**—After a discussion of the subject and reported cases Hirsh concludes: 1. An eruption limited to the buccal and labial mucous membranes and characterized by the presence of an irregular red spot with a bluish-white center, is always present in beginning measles. 2. These spots are present from twelve hours to five days before the cutaneous outbreak. 3. The number of these spots bears no relation to the severity of the attack. 4. These spots will be found in no other condition of health or disease.

6. **Physical Diagnosis of the Stomach and Viscera.**—The methods of examination in cases of disease or abnormalities of

the stomach and associated organs are described here by Loveland, who illustrates by diagrams some of the conditions he has observed and diagnosed. He takes up the various methods of physical examination separately, and of inspection general and local, the temperature, percussion, auscultation, etc., and thinks that we can determine the shape, size, location, presence, and in many cases the character of tumefaction, if such exists, and also the sensitiveness on pressure. This information may be secured in relation to stomach, liver, spleen, or kidneys by purely physical methods, and when we have the opportunity to add to this the history and symptoms, and in selected cases the chemical analysis of the contents of the stomach, and urine, and examination of the blood, in addition to the clinical appearances, there will be very few cases in which any serious doubt as to the exact diagnosis will remain long in our minds. Yet, in the face of some very perplexing problem in diagnosis, we may console ourselves with the fact that on rare occasions, cases occur so negative in all the signs, both physical and clinical, that they will defy the diagnostic ability of the most experienced. Such consolation, however, should not be ours until we have gone so thoroughly into the case as to leave nothing undone which might add to our knowledge of that particular condition.

7. **The Roentgen Rays.**—The errors that are possible with the Roentgen rays as a means of diagnosis are discussed by Beck, who calls attention to the fact that the trouble is not in the pictures or skiagraphs produced, which it must be remembered are only silhouettes or shadows, but in the interpretation of them by the unskilled or careless. He calls attention to the importance of knowledge of minute anatomical details, illustrating it by the trigonum tarsi, a bone which is present in 7 or 8 per cent. of cases, but which is sometimes mistaken for fracture and has caused some medicolegal complications. The special trouble with the skiagraph will be in regard to joints and the more complicated the joint, the more complex the picture. Other things which may produce difficulties in diagnosis are callus formations, the recognition of the union of the joint in the growth, diaphyses and epiphyses and the location of foreign bodies.

8. **Tubercle Bacilli in the Nose.**—Jones has examined a number of cases of tuberculous and other patients, and finds that virulent tubercle bacilli are to be found in the nasal cavities of healthy persons, but not so frequently as in those who have the care of the tuberculous. His studies show the danger from inhalation of dust, especially in localities where the tubercle bacilli are liable to be given out.

10. **Health Resorts.**—The points of special importance to be known in regard to health resorts are described by Otis, who takes up the plan suggested by Dr. Phillips, of the United States Weather Bureau, as a simple and plain but satisfactory method of giving the facts in regard to the climate of any region. It includes the questions of temperature, humidity, precipitation, direction and force of winds and the averages as to clear and rainy weather. Among other things he mentions the characteristics of the locality, whether wooded, hilly or undulating country, the character of the soil and the condition of artificial essentials, such as lodgings, water-supply, protection from contagious diseases, amusements, diversions, etc.

12. **Carbolic Acid.**—Phillips reports further results in the use of pure carbolic acid in the treatment of mastoiditis and chronic suppuration of the middle ear, in all of which he used it with beneficial effects. In none was there any inconvenient or unfavorable symptoms after following it with alcohol as mentioned in his former article. He also quotes notes from Parker, house surgeon to the Manhattan Eye and Ear Hospital, giving similarly favorable experiences.

14. **Exstrophy of the Bladder.**—Beck describes an autoplastic method for the restoration of the retentive powers of the bladder in congenital exstrophy by an anterior muscular wall. In cases where the flap operation is impracticable he takes the recti muscles, incises them along their internal margin to the extent of a little less than one-half their thickness and forms flaps of the same. After uniting the walls with thin iodoform-silk sutures the reflected muscular flaps are united above them, thus producing a small but virtually normal bladder, protected by a firm muscular layer, which is likely to distend later on. Further observations of the case are promised in the future.

18. **Laryngitis and Asthma.**—Glasgow reasons that asthma is due to a reflex irritation in the upper portion of the respiratory tract, and according to his observations the interarytenoidal region seems to be the most frequent site of the irritation. This is due in many cases to primary laryngitis and the causation of asthma is therefore laryngeal rather than nasal in these cases. Four cases are reported illustrating his views. He thinks that we need to use constitutional as well as local measures in this condition since the latter alone are generally not sufficient to incite respiratory spasms.

19. **Suprarenal Extract.**—The striking results from the use of suprarenal extract and its great value in nasal affections are apparently not entirely without corresponding inconveniences. Hopkins shows where secondary hemorrhage has been produced in his own practice and in those of many others when they have not applied intranasal packing. The powerful stimulation to contraction does not suffice to prevent indefinitely but only to delay the paralytic stage that follows. He does not offer these facts as an argument against the use of suprarenal extract but only to call attention to some points of danger that can be avoided by the easy recourse to packing after its use.

22. **Hysterectomy for Fibroids.**—Davenport reports two cases of operation for fibroids with later death of patients. The prominent feature of the two cases was the size of the tumor, but there are other dangers which he mentions as not less serious. In looking over his cases for hysterectomy for fibroids, he finds in his last 100 abdominal operations 19, of which these two only were fatal. He had in his 19 cases, 2 cases of malignant degeneration, 3 of anemic necrosis, one of the latter being malignant as well, thus making 6 altogether of the 19 where life was threatened. With these possibilities in such proportion he thinks that any cases where symptoms occur which interfere with the patient's enjoyment of life, operation should be advised, though not universally in fibroid, many of these causing so little inconvenience and growing so slowly that this is not indicated. Many cases also offer other objections, such as interference with child-birth, etc., and where the patient desires it, he thinks we should not hesitate.

23. **Hysterectomy for Myoma in America.**—Cushing reviews the contributions to gynecologic surgery made in this country with special reference to operations on the uterus and sums up the changes in the methods as follows: Entire abandonment of extra-abdominal treatment of the stump, wide trial and substantial rejection of vaginal hysterectomy as an operation of election in cases of myoma and salpingitis, the establishment of indications for the retention of cervix uteri as compared with total extirpation, the adoption of a universal method by most operators, the disuse of drainage wherever possible and the common recourse to operation in small hospitals by the local surgeons, which has its disadvantages since the skill and experience of some of these are not equal to their zeal. He gives the indications for total hysterectomy as compared with leaving a portion or the whole of the cervix which is generally the better course. 1. It makes the operation shorter and easier, there is less chance of hemorrhage during operation and so much cellular tissue is not opened for the oozing and decomposition of the blood. 2. There is somewhat less chance of infection of the wound where only the small cervical canal is cut across and instantly closed by the double tenacula than when the whole vault of the vagina is opened. 3. The vaginal portion is a seat of sexual feeling, and if it is present the patient does not feel as much mutilated as when it is gone. 4. The lower parts of the broad ligaments with the cervix, forms a better support to the pelvic contents than does the simple union of the vault of the vagina. Total hysterectomy should be performed; 1, when the cervix is enlarged and diseased; 2, when it is suppurating or septic; 3, when there is no suspicion of malignant disease, and 4, when vaginal drainage appears desirable.

24. **Perineal Tears.**—After first noticing the causes of these and the impossibility of always avoiding them, Boland sug-

gests immediate operation and gives his method. He thinks the use of the head mirror a valuable adjunct in the operation.

25. **Cottage Sanatoria.**—Klebs calls attention to the value of the open-air and cottage treatment of tuberculosis and gives what he considers a model plan of an institution of the kind.

28. **Mastoiditis.**—It is often said that the only rational means of aborting acute inflammation or mastoiditis is by the use of dry or moist heat. McKernon condemns this view, showing by cases in his practice that it is not effective. On the other hand he prefers the use of cold by the ice coil applied snugly over the process, with free purgatives administered; the canal irrigated frequently with warm bichlorid solution and the patient kept on a fluid diet. The use of moist heat may seem to diminish or stop the pain, but it does so at the expense of softening and undermining the tissues beneath it and thus advancing the disease.

29. **Spinal Analgesia and Labor.**—Stimulated by the reports of the surgical use of spinal analgesia by Tuffier, Marx has used the same method in labor with remarkably good effects in the cases in which it was employed. The patients were delivered without any pain or any knowledge of it, for they lose consciousness of pain when the injections are made thoroughly and successfully. He does not prophesy as regards the future utility of this means, but apprehends no danger from its employment. Whether any remote dangers will follow the use of cocain when applied, further experience will have to show. He suggests the use of this method in cases of prolonged and tedious labor, as anesthesia in this form does not at all interfere with the natural course.

30. **Symptomatology of Consumption.**—The first early symptoms of pulmonary tuberculosis are rarely significant to the patient with lung trouble, according to Lyle. If the temperature was taken oftener we should recognize many more cases. The different forms of consumption, acute, caseus, fibroid, etc., and their symptoms are noticed in detail.

32. **Fractures.**—The average results of treatment, Manley says, are excellent, but while authors are clear as to how we should treat fractured bones, they say but little of the limb. The limb should first be wholly wrapped in cotton wadding and should be supported laterally. He does not believe in the use of the bandage over the surface of the limb immediately after the fracture and the less splinting we apply over the limb which is the seat of diminished vitality the better. The first principle is to put the limb in a comfortable position and we should discard every sort of fixation until we feel sure of survival of the limb. In every form of fracture involving the shafts of the long bones or joints of the extremities our first and most important concern is the preservation of the circulation. In open fractures, after rendering the parts aseptic, moderate tamponade with gauze, with moderate pressure will generally suffice, and if the larger arteries are lacerated a tourniquet properly adjusted is to be relied on. The Esmarch bandage should not be indiscriminately employed over more than two hours. In so-called simple fracture the arterial trunks may be seriously injured, threatening the vitality of the parts, and we should place the limb in such a position as to best favor the establishment of circulation. The preservation of vitality of the part without regard to the condition of the joint is most important. Splints and bandages must be applied in the case of arterial thrombosis until we are sure that the circulation is turning toward normal. In the case of dry gangrene there is no haste to amputate until the nature of the processes are thoroughly defined. As there are good reasons to believe that the union of fractured bones is sometimes delayed, or even wholly arrested, by premature or too rigid adjustment in fixative apparatuses, or in consequence of too long employment, caution should be observed not to unduly constrict the circulation by any sort of mechancial appliance; rather, on the contrary, it is probable that in not an inconsiderable number of fracture cases the circulation of the limb is favored, the nutrition improved, reparative osteogenesis hastened and perfected by occasional moderate motion, massage, and only such adjustment as will provide support alone to the limb, without simultaneously exerting too much pressure.

37. **The Office of Motherhood.**—Mark thinks that no child should be born undesignedly, as is too often the case at the present time, and that great damage is done by too much child-bearing by women. He lays stress on the importance of maternal impressions and especial care during pregnancy to see that all the conditions and environments are the most favorable possible.

40. See abstract in The Journal, xxxiv, p. 1339.

44. **Vesical and Urethral Traumatism During Labor.**—This paper does not consider the major injuries of the bladder and urethra, but only those cases in which no external wound is produced. The urethra is injured during labor by direct bruising. The direct consequence is hemorrhage of the mucous membrane, producing retention and tenesmus, requiring the use of the catheter. The catheter should be straight, with a very slight curve at its vesical end. The eye should be situated in the center and the tip be carefully polished. The ordinary female catheter is liable to do harm. If the suffusion in the urethral wall is not reabsorbed, but becomes organized, the subsequent shrinkage of the connective tissue may produce quite extensive strictures, which can be removed only by urethrotomy. All urethral lesions caused by squeezing are most likely to occur in cases of simple flat pelvis. The urethra may become kinked and double up. Another variety occurs if only the urethral wall is carried downward; this is most likely to occur in the forcible forceps operation, which drags down the urethra, paralyzes the sphincter and produces incontinence even after involution is complete. Traumatisms of the bladder may be divided into two groups: traumatic desquamative catarrh and dislocations. By studying a great many cases, Kolischer has been able to prove that there is always a pronounced edema in the bladder during labor, favoring desquamation through mechanical injuries. Hemorrhages may occur from frequent pressure and the epithelium is then thrown off. Such losses of the epithelium cause the patient the sensation of heaviness and soreness and tenesmus; diagnosis of cystitis is often made and treatment with caustics or astringents is employed to the patient's injury. Traumatic dislocations are caused by the descending fetal skull, which drags the bladder from its seat. It may be completely dislocated and in this case complete incontinence results. This may have a further effect, producing trouble in the ureters and dilatation. The only method of treating this complication is operative. The bladder must be dissected out, replaced in its normal region and secured there by sutures. These injuries usually follow forceps, and especially high forceps, operations, and furnish another reason for preferring the Breus axis traction forceps, which allows of more mobility of the head.

45. **Chronic Inversion of the Uterus.**—In Atlee's paper chronic uterine inversion is described and he shows that there are times more favorable than others for its replacement; that for each individual case some one particular method is most liable to be successful. He also shows the great difficulty that may be encountered in certain conditions in establishing a satisfactory diagnosis and reviews the procedures which have overcome this difficulty in the hands of the most experienced men.

46. **Gall-Stones.**—From the case reported, Gordon concludes that an operation is indicated after it is well established by repeated attacks that gall-stones are present. Gall-stones may be present in the gall-bladder without giving rise to colic, but are the cause of more or less digestive disorders and impairment of general health. From his experience and the reports of others he is satisfied that many cases are better treated at the time of operation by closing the bladder, dropping it back into the cavity and closing the abdominal wound. Patients treated by drainage are often slow to recover and liable to be left with biliary fistula lasting for a long time. Great care should be used to cleanse the bladder before closing it, rendering it as nearly aseptic as possible. While gall-stones may occur after operation, he thinks they are no more liable to after closure than after drainage.

51. **Encephalocele.**—This condition occurring in the skull, which is analogous to spina bifida, is, as a rule, readily diag-

nosed and its prognosis is unfavorable if let alone. There are, however, some difficulties in its differentiation which are pointed out by Beck. Three cases are reported, in two of which operation was performed, with success in one, the other died of purulent meningitis. In the third case the tumor was gradually diminished and finally destroyed under pressure with large iodin-gauze collodion dressings. He thinks that the prognosis is improved with aseptic methods and that the Roentgen rays have added a further element of security in the diagnosis which also improves the therapy of the condition.

52. **Cardiac Disease.**—Morrissey is opposed to gloomy prognoses in the case of heart murmur and advises the practitioner to consider the condition of the cardiac walls, the probable length of time the lesion has existed, the presence of dilatation or hypertrophy, and also the occupation and temperament of the patient. Murmurs do not invariably mean endocarditis and when a man has one of which he is unconscious, where the heart is acting perfectly, and his work is not of a laborious character, and he is past the period where rheumatic infection is liable to be stimulated into renewed activity, he is not to be regarded as a bad risk for insurance, or to be refused a policy commensurate with the degree of cardiac inefficiency. Increased presystolic murmur does not always indicate a mitral stenosis, nor has so-called musical apex murmur any significance. From the standpoint of longevity, aortic stenosis is a favorable lesion and the writer does not agree with some authors who say that it occurs mostly after middle life. He says, never hesitate to ask a patient to return for further observation. There are more snap diagnoses made in the study of cardiac disease than of any other disease of the body.

64. **Asexualization.**—Brower reviews the statistics of the increase of crime, insanity, idiocy and their ratio with that of the general population. He points out how much of this is due to the continuation of bad heredity. The remedy he suggests is asexualization of criminals and defectives, which he thinks is worthy of consideration.

65. Published in THE JOURNAL, vol. xxxiv, p. 959.

67. See abstract in THE JOURNAL, vol. xxxiv, p. 1335.

74. **Subphrenic Abscess Following Appendicitis.**—Baldwin reviews two cases of subphrenic abscess, accurately diagnosed and treated by operation with success. They are, he thinks, the forty-fourth and forty-fifth cases of this complication that have been reported. In the first case the appendix was behind the cecum and he was inclined to believe that the infection extended downward and behind the peritoneum; the entire abscess was therefore retroperitoneal. When the appendix is free in the peritoneal cavity one would expect to find the intraperitoneal form of infection, it being carried by peritoneal currents from the region of the appendix to the diaphragm. His second case was of this variety. The diagnosis in this case must be based on the continuance of the infected symptoms after removal of the appendix or subsidence of local inflammatory symptoms. A careful examination should reveal some tenderness in the region of the liver with depression on its lower border, and pain in the right shoulder has been noticed in a number of cases, and is an important factor. Hiccough is rather a common symptom and an important fact is that frequently in these cases the abscess cavity contains gas as well as pus and this may render the diagnosis somewhat more simple. In these cases the previous history of the patient pointing to abdominal, rather than to thoracic, trouble, normal vascular murmur and fremitus at the apex with a sharp line of differentiation from the amphoric respiration found below and the descent of the line of normal fremitus with very slight displacement of the cardiac apex and slight bulging of the intercostal spaces without chest-wall immobility are the points noticed by Leyden as important. If the disease is not recognized and not surgically treated the mortality is large, but when it is recognized the mortality should not exceed 50 per cent. or less. He prefers to make an incision well back on the right side so as to strike the abscess directly, if extraperitoneal, or through adhesions if time has permitted their formation. If no adhesions are found, this will best allow drainage and protection of the general cavity. While most of these abscesses can be reached, as in his two cases, by going below the ribs entirely, it might be necessary in some cases to resect the tenth, ninth or eighth rib to reach the abscess more directly. The danger of wounding the pleura must not be overlooked, therefore he prefers the infracostal incision.

75. **Tuberculin Reaction.**—Moorehouse reports cases with temperature curves and a number of tuberculin injections in patients in whom the diagnosis was difficult. He thinks the measure is justifiable in such cases. Of the 13 positive reactions, 2 had a temperature of 104 F. or above; 8, 103 or 104 F.; 1, 102 or 103 F.; 2, 101 or 102 F. The time of high temperature varied from eight to forty-eight hours after the injection. Tuberculin was given to a number of patients in which there was no reaction, but they are not reported.

85. **Pneumonomycosis.**—Pearson and Ravenel report a case of pneumonomycosis which was attributed to the aspergillus fumigatus. This mold forms no toxins, but causes trouble mechanically by traumatism and causing necrosis of the cells. In this case, which occurred in a cow, they consider it one of primary aspergillosis because of the predominance of this fungus in the nodules and the lack of other lesions which could cause death. They consider the case of interest as the only one of this character ever observed in America.

98. This article has appeared elsewhere. See THE JOURNAL, vol. xxxiv, p. 1651.

99. **Unna's Dressing.**—Unna's paint or dressing is highly recommended by Michel for chronic ulceration of the leg. It is prepared thus: Take of water and glycerin, each 10 parts, and of gelatin and white oxid of zinc, finely powdered, each 4 parts. The gelatin should be of the best quality. Dissolve the gelatin in water by means of the water-bath. While hot add the glycerin and finally the oxid of zinc, stirring vigorously and continuously until cold. Before application the leg should be washed thoroughly with soap and water, dried and rubbed with alcohol. When the paint is rendered fluid by heat it is applied to the leg with a paint-brush, extending the dressing from a little below the knee down nearly to the ankle. After the leg has been thoroughly painted, an ordinary bandage is applied, which must be put on without wrinkles or reverses, and necessarily, therefore, in parts. Above this another layer of paint is applied and so on. The dressing should be from three to five bandages in thickness. It should be worn from four to eight weeks, though it may need more frequent change. This plan of treatment is applicable to all ulcers of the leg and can be made to answer other indications than those here mentioned.

121. **Non-Roaring Stethoscope.**—Scott describes his experiments to eliminate the roaring sound heard in the stethoscope. He has constructed a non-roaring monaural stethoscope which consists of a bell with a spring, the bell composed of glass and metal which does not allow the sounds of muscular contraction to be conveyed from the fingers and which can be applied easily to the chest wall or other parts of the body. He has found it especially advantageous in examining children or small areas.

122.—This article appeared in THE JOURNAL of July 21, p. 131.

127.—See abstract in THE JOURNAL, xxxiv, p. 1197.

130. **Hemoptysis.**—The author divides the varieties of blood-spitting into two large clinical classes: pure or large hemorrhages, and, impure or minor hemorrhages. The conditions to be fulfilled in every form of treatment are to lessen blood-pressure and to increase resistance at the bleeding-point. For while the venous pressure is lower than the arterial, it is a good deal higher than it would be had the total caliber of the venous been greater than that of the arterial vessels,

which is not the case, as shown by Winslow, Ewart, Santorini and Haller. Ergot also acts only beneficially by lowering the venous pressure and that it does act beneficially sometimes and sometimes not in hemoptysis is a known fact. The arterioles and veins also act similarly as regards the effect on blood-pressure by ergot. When the patient is first taken ill the pulse is full and rapid, but this depends somewhat on the temperament of the patient; if not nervous, it may be slow and steady with no rising temperature, and these cases often do well without any special treatment. He asks how we are to lower a lateral pressure on the blood-vessels. There are only two ways of doing this in the pulmonary vessels: By acting on the heart-beat or on the vascular approaches to the wounded vessel. An injection of morphin with ergot is often sufficient to stop the bleeding. The next thing is to prevent recurrence and Frazer considers that further injections may be required. Rest in bed is necessary and the length of time is important, too little is often given. The diet should be light and cool and he is careful to prohibit any purgatives while the heart's action is excited. Discomfort is not usually felt in this regard for three or four days, and then oil or glycerin enemata are sufficient. The cough may be troublesome, but if not controlled by injections, it may yield to chloral or codein. Pain in the chest is usually met by counter-irritation. Vomiting may occur, but seldom requires treatment; if persistent it generally yields to one-twelfth grain of cocain. If the hemorrhage is purely arterial, ergot is contraindicated. The other drugs and agents mentioned are aconite, which he has found very useful, and digitalis in mild cases. The ice-bag has a slight effect, hardly worth the trouble it gives. Turpentin, sulphuric, tannic and gallic acid, etc., are useless.

132. **Heroin.**—According to Brown and Tompkins' experiments, in which they gave this drug in thirty-four cases for relief of pain, and as a hypnotic in sixteen, it would appear that heroin is a safe, reliable analgesic, which can be repeated if necessary without producing habit or doing any harm.

The Lancet, August 18.

Physiologic and Therapeutic Action of Digitalis. T. Lauder Brunton.—The action of digitalis has long been known and is explained by Brunton as partly due to its effects on the inhibiting center of the circulation and in part also to its contraction of the arterioles, raising the blood-pressure in the general circulation. The diuresis which digitalis produces is probably due to increased pressure within the glomeruli of the kidneys. The chemical composition of the drug is complex; the chief components, according to Schmiedeberg, are digitoxin, digitalin, digitalein, digitonin, and digitin. The last two have so little physiologic action that they may be dismssed from consideration. The crystallized digitalin of Nativelle consists chiefly of digitoxin; the digitalin of Homolle and Quevenne consists chiefly of digitalin and the German digitalin consists chiefly of digitalein and digitonin. The action of these drugs appears to be nearly alike in kind, but differs in degree, digitoxin being far the strongest. Nativelle's digitalin is found by Widal to be eight or ten times stronger than amorphous digitalin, and in daily doses of from one to two milligrams slows the pulse, while from three to ten milligrams of Homolle's digitalin are required. The German digitalin may be given in doses three times as great as Homolle's, or ten times as great as that of Nativelle. The insoluble kinds of digitalin—Nativelle's and Homolle's—cause considerable local irritation when used subcutaneously and may even cause abscesses, though the solutions are perfectly sterile. Soluble digitalin may be used subcutaneously in the form of a 1 per cent. solution in equal parts of glycerin and water, 1 to 2 c.c. being injected two or three times a day. Digitalin and its active principles regulate the heart's action, assist failing circulation and act as diuretics. In cases of palpitation and functional irregularities small doses, such as 10 minims of the tincture, are sometimes very useful. This is well marked in cases of palpitation brought on by physical strain, anxiety or worry. Where stomach irritation has produced it in a reflex way, better results are obtained by bismuth and rhubarb. In cases of aortic regurgitation with good compensation digitalin is quite unnecessary and may be harmful. It is, however, of utmost service when the mitral valves become incompetent in consequence of damage to the valves themselves or dilatation of the cardiac orifices from weakness after infectious diseases or from failure of a hypertrophy consequent upon aortic regurgitation or renal disease. It may be useful, moreover, before the heart has dilated so as to render the mitral valves incompetent, by lessening the ventricular regurgitation during diastole, and thus diminishing the amount of blood which can regurgitate. By its action on the arterioles it also aids in lessening the flow. To get the best results in severe cases, the use of the drug should be associated with rest in bed and massage. In conclusion, he speaks in regard to the dangers of the drug in cases of fatty heart and very high tension. If we have fatty degeneration with normal muscular fibers of the arterioles, the resistance to cardiac contraction will be increased and the heart, already disabled, will be further embarrassed. In such cases we should simultaneously administer nitrites, such as nitroglycerin, nitro-erythrol or ethylnitrite, most commonly given in the form of spirit of nitrous ether. The same precaution should be adopted where the arterial tension is high and the heart is just beginning to fail, and in such cases it may be well to avoid digitalis altogether; but if it is given, the nitrites should accompany it and great attention should be given to the condition of the bowels and the liver.

Some Remarks on Cancer of the Breast. Skene Keith.—The three questions usually asked by the public in reference to cancer are: 1, is it curable? 2, is it hereditary? 3, is it curable by operation? Keith believes that cancer is increasing to a certain extent, but this is apparently magnified by the better knowledge of pathology and diagnosis. When we come to heredity the statistics are embarrassed by the fact that the public do not like to admit this element. It is most certainly curable, but not in every case, even in those apparently favorable to operation. The first thing to be decided is what is a cure. Here the unsatisfactory question of time comes in. If a patient died twenty years after the cancer of the breast had been removed, it could not be said positively that it would not have recurred had she lived long enough. Some have fixed the time at three years, after which a cure can be claimed, but Keith thinks this is too short and even five years would be the same. Every year, however, increases the chances of life. The time limit may be suitable for statistics, but it is not assurance to the patient. He remarks in regard to the statistics of operations that it is possible some of the operations of the past have not been done with sufficient care. He thinks the Halsted operation, from its severity, must have a certain amount of mortality in weak subjects, while the removal of the breast and axillary glands is an operation unaccompanied by any extraordinary risk to life. What is more important than the removal of one or both pectoral muscles is the removal of the superficial fat of the breasts. It has been shown of late that the lymphatics do pass freely into the superficial fat and it may be that if extra attention is paid to this part during the course of the extensive operations practiced by some, the improved results are due to this rather than to the free removal of muscle.

Australasian Medical Gazette, July 20.

The Effects of Migration from the Northern to the Southern Hemisphere. R. Humphrey Marten.—In this address the author gives his own observations and impressions regarding the difference between the native Australian and the native Englishman. In the Australians maturity comes earlier, they are energetic, muscular, and more inclined to be dark-complexioned than are the British islanders. With the early maturity he thinks there is probably an early senility. The Australian's teeth are extremely bad as a rule, and this is due, he thinks, to the large amount of butcher's meat consumed by them, but he comforts the Australian with the statement that, according to the latest French statistics, good teeth go with a high death-rate. In stature the Southerners are rather above the British standard. Their families are as large as in the northern hemisphere, and the majority of births occur in the corresponding seasons—not the same calendar months. In regard to their diet, the Australians are the greatest meat-eaters in the world, and head the list in the amount of tea consumed per individual, except perhaps the Chinese. As a whole they are not a beer-drinking people, but prefer whisky, which he credits to the ease of transport. Beauty fades earlier and as they live at a higher pressure, the length of life will probably be affected. As regards diseases in Australia and Great Britain, if any practitioner were asked if there were any national disease peculiar to Australia he would at once answer hydatids, while rickets is almost unknown. Diphtheria, typhoid, etc., are as common as in Europe. Typhus fever, cholera and relapsing fevers have apparently never been imported. Pulmonary tuberculosis appears to be about one-half as frequent as in Europe. Scarlet fever is milder. Smallpox has never gained much footing, but he thinks it would be disastrous if it occurred, owing to the unvaccinated condition of many of the inhabitants. The Australian colonies have so far escaped hydrophobia. Rheumatic fever, according to his experience, is very rare, while rheumatoid arthritis is fairly common and there is a peculiar form of joint-trouble allied to chronic rheumatism which resembles arthritis, but is not permanent. Diabetes is about as common as in Europe; gout is rare. The cirrhotic variety of Bright's disease is about as frequent as in Europe. The Australians also have their share of summer complaints and a large amount of appendicitis. Bronchitis is not a common disease, but pleurisy and pneumonia are perhaps as common as in the colder North. In his opinion, heart disease is less frequent than in Europe, but this is probably to be explained by the fewer cases of acute rheumatism. There is nothing special in regard to nervous diseases, excepting the invasion of the brain by hydatids. Syphilis appears to run about the same course as elsewhere. It has struck him that cases of ectopic pregnancy occur more frequently than in England and to go without seeing one in his practice for six months is a rarity. Gynecologic complaints are, he thinks, dependent largely on the customs of the country and they are more inclined to favor the American and continental schools than the British. Eye, ear and nose diseases furnish magnificent fields for the specialist.

Archives Generales de Med. (Paris), July.

Hemorrhages in the Suprarenal Capsules. F. ARNAUD.—The hemorrhage did not produce any appreciable symptoms in more than half of the eighty cases analyzed in this review. In 6.3 per cent. the capsular hemorrhage became manifest as a large hematoma or abdominal tumor, and even in these cases the exact diagnosis was made only once during life. The syndrome of the peritoneal type existed in 7.59 per cent. There was laceration of the capsule in all, and a hemorrhagic exudation into the peritoneum in four, with perforation in one. Symptoms of capsular insufficiency were evident in 10 and of suprarenal apoplexy in 19 per cent. The latter was characterized by sudden death in a few hours to three days, sometimes accompanied by nervous symptoms, such as delirium, convulsions, coma, hypothermia, etc.

Hemorrhage in the Cerebellum or Peduncles. R. TOUCHE.—Thirteen cases are described in full, and in nearly all the autopsy findings are given. In one, a healthy woman of 66, the classic cerebellar syndrome appeared, vertigo, etc., falling always from the left side. No lesion was found in the cerebellum, merely a hemorrhagic focus with destruction of tissue, in the left middle peduncle of the cerebellum. Another case confirmed the possibility of sudden blindness from hemorrhage in the aqueduct of Sylvius. In another patient the head and eyes deviated to the right; she was eight days unconscious and had a tendency to roll out of the right side of the bed. The autopsy disclosed softening of the inferior surface of the left lobe of the cerebellum.

Malarial Infection from Plants. VINCENTE.—A boy of 9, at boarding school, and his brother, two years younger, at home in Paris, succumbed simultaneously to severe malarial infection, both isolated cases. Vincente, after much research, traced the infection to three large oleander trees which had been brought into the living-rooms of the residence at vacation time. The mother had contracted severe malarial infection several years before the birth of the children, and he attributes the present outbreak to the survival of the malarial germs on or in the plant tubs. The soil, warmth and constant moisture in these very large tubs combined to form a favorable culture-medium for germs. The plants in this instance were covered with innumerable plant-lice, which swarmed all over the room, on the furniture, clothes and skin of the inmates, and were even found in the drinking water. He is inclined to incriminate these insects and is now making a special study of them to determine the question.

Archives Orientales de Med. et de Chir. (Paris), July.

Cure of Malignant Ulcerations With Cynoglossum. TSACONAS.—About twenty months ago Tsaconas found in a monastery on Mount Athos a MS., dating from 1600, while referred to numerous cures of benign and malignant ulcerations obtained with the pulverized root of the cynoglossum applied externally. He at once sought opportunities to test this remedy, and now announces that with it he has cured five cases of epithelioma of the face in patients from 50 to 84 years of age. The photographs "before and after" show the complete disappearance of the neoplasms, with merely a small defect in some and complete restitution in others. The ulcerating surface is first cleansed with a solution of boric acid and then dusted thick with the powder twice in twenty-four hours, and covered with a cotton bandage. The cure was complete in five months in most cases, the extremes being four and eight months. Tsaconas uses the dried roots, blossoms and leaves of the cynoglossum. He also reports a number of simple ulcerations and even of moist gangrene after traumatism cured with the powder. Poulopoulos has successfully used it internally in doses of 1 to 2 gm. a day in seven cases of ulcus rondus and in several cases of cancer of the stomach, with material improvement.

Bulletin de l'Academie de Medecine (Paris), August 7.

Connection Between Genital Functions and Arsenic in Thyroid Gland. A. GAUTIER.—It has been demonstrated that iodin and arsenic are normally constant constituents of the thyroid gland, in which they are stored in the form of specific proteids. They have also been found in the organs of ectodermic origin, the brain, skin and its appendages, hair, nails, etc. Normal blood contains infinitesimal amounts, but the menstrual blood, except in the case of anemic subjects, contains such large amounts that almost the entire supply must be thus voided each month. This confirms the theories in regard to the close connection between the thyroid and the genital functions. In the female the surplus of the phosphorized nucleins of the thyroid gland and possibly of other glands, is periodically diverted to the genital organs, where it serves to nourish the fetus or is expelled in the menstrual discharge. In the male this elimination occurs through the skin and its appendages, in the shedding of the hair, beard, fur, horns, "nuptial plumes," etc. Women taking organic arsenic in the form of cacodylate find that the hair grows and the menses become regular, while on the other hand, nuns who keep their hair cropped close, note that the menses become irregular if the hair is cut during the molimen. The success of Brown Séquard's extract of the testes is due to the easily assimilated phosphorized principles which it contains, supplemented by the addition of the iodin and arsenic in the thyroid gland. If this gland has deteriorated, as in consumptive, myxedematous, goiterous and thyroidectomized persons, vitality languishes, the genital functions are affected, and the skin and brain degenerate. It seems to be evident that the organic phosphorus of the nucleins is indispensable to the functional activity of the cell-nuclei, but that it is the arsenic and iodin which impart to these nucleins and to other specific principles a superior activity which enables them to react on the entire organism, more especially on the skin, brain and organs of reproduction.

Regeneration of Bone-Marrow in the Dog. V. CORNIL.—Both marrow and bone grew again in the normal place after the tibia had been partially scraped out, thus reconstituting the bone, in three months after a preliminary phase of ossification in the marrow cavity. Bone-marrow isolated by removing the bone around it after amputation, first becomes ossified and then transformed into fibrous tissue. Transplanted marrow undergoes fibrous transformation without a previous stage of ossification. This research confirms the temporary character of accidental ossification.

Sarcomatosis Cured With Sodium Cacodylate. Petrini.—A patient, 40 years of age, was treated with sodium cacodylate as a last resort for diffuse sarcomatosis commencing on the pharynx. Seventy injections were made in all, 13 cg. being the daily maximum dose. One of the tumors was excised, which proved to be an embryonal, vasoformative-celled sarcoma, non-pigmented and non-melanic. All the lesions retrogressed to complete disappearance with a supplementary course of arsenical mineral water. In a second case, improvement was evident with similar treatment, but the general process was too far advanced to prevent the fatal termination.

Pathogenic Blastomycetes in Carcinoma. Leopold.—Several hundred cases of carcinoma have been studied by Leopold with a special microscope, which keeps the section warm and moist. He found blastomycetes frequent, and was able to trace their development and obtain a pure culture in four cases. He also secured positive results in animals inoculated with them, particularly marked in one instance in which a rat was inoculated with a pure culture from a cancer on a female patient, and reiterates his assertion that the blastomycetes are factors in the etiology of carcinoma.

Presse Medicale (Paris), August 8.

Experimental Research on Thyroid Infection. H. Roger and M. Garnier.—The Koch and Eberth bacilli and staphylococci were the micro-organisms studied. The experiments showed that intense infection—even if brief—induces cellular alterations, while protracted infection determines interstitial lesions. The entire gamut of visceral inflammations can be reproduced by injection of microbes into the thyroid arteries. Varying the dose or the virulence of the cultures it is possible to induce interstitial thyroiditis: hemorrhagic, with a lively leucocyte reaction and sclerosis, or parenchymatous, with acute necrosis and degeneration of the cells, and epithelial proliferation leading to neoplasia.

Diagnosis of Coronary Angina Pectoris. P. Merklen.—Angina pectoris of coronary origin is distinguished by retrosternal pains radiating into the cervicobrachial nerves, and distress. They appear as sudden attacks isolated, usually consecutive to unusual effort, sometimes to exposure to cold or violent emotion. There is no pain nor hyperesthesia during the intervals and its non-spontaneous character is an important aid in differentiation. It is a neuralgia and not a cardiac neuritis. The attack ceases under the influence of repose, the patient usually holding his breath to ensure absolute immobility.

Revue de Chirurgie (Paris), August 10.

Sebaceous Adenoma of the Face. G. Curtis.—The writer classes sebaceous adenomata as simple and complicated, both benign. In the first the stroma is not altered, but in the second there is varying degeneration of the stroma and of the vessel-sheaths. In a case of the latter variety described and illustrated the tumor was of the size of two fists, with a broad base of fibrous tissue on which it was freely movable. The ulcerating, bleeding, fetid surface and the emaciation of the patient, a man over 56, suggested malignancy, but the adenoma had no deep prolongations and removal was simple.

Extraction of Nail from Bronchus With Magnet. Garel.—A child with an iron nail 53 mm. long in the right bronchus was relieved by tracheotomy. A magnet was inserted in the opening, which attracted and removed the nail.

Osteoplastic Amputations. Z. Samfirescu.—When a long bone has to be amputated in the shaft it is possible to make a diaphysial bone-stump which fulfills all the conditions of the trunk and can be placed immediately in the prothesis without the slightest remote inconvenience. The bone-stump thus obtained is solid and not sensitive to changes in temperature. The shaft is sawed across in three places, about as far apart as the bone is wide, the highest amputation on a level with the highest point of the incision in the soft parts. The small cylinder of bone beneath it is then removed, and the cylinder below this is sawed lengthwise in half, and one-half also removed. This leaves only the remaining half of the lower segment still hanging by the periosteum flap. It is brought up across the stump of the long shaft and held in place with a stitch in the bone on each side.

Revue Generale de Ophthalm. (Paris), July 31.

Periscopic Glasses. F. Ostwalt.—By taking photographs through the lenses, in similar conditions to those of the lens in relation to the eye, Ostwalt has discovered that judiciously selected menisci or planoconcave glasses are far preferable to the ordinary bispherical lenses for divergent glasses for distant vision. Instead of the biconcave, therefore, corresponding periscopic glasses should be prescribed, either meniscoid or planoconcave or asymmetrical biconcave. He gives a curve to guide the oculist in ordering divergent periscopic glasses and the manufacturer in making them. For convergent glasses the meniscus bulges too much to be practicable, particularly for patients after operation for cataract. But even in this case the symmetrical bispherical shape is not so favorable as the asymmetrical biconvex, which, with direct vision, gives the minimum of sphericity error, the front side having a radius of curvature six times larger than the other.

Berliner Klinische Wochenschrift, August 6.

Alterations of the Ganglion-Cells in Mental Diseases. E. Meyer.—The changes in the ganglion-cells in several groups of psychoses, with and without a clinically appreciable cause for the mental disturbances, were carefully studied. The same negative results were obtained in each, confirming the general experience that the ganglion-cell reacts in the same specific manner to irritations of all kinds, the alterations noted differing merely in the intensity and extent of the process, as can be determined with the present methods of research.

Idiopathic Transient Disturbance of Consciousness. Placzek.—The symptoms presented by persons resuscitated after being hanged, showing disturbances in the circulation of the cortex, were recalled by two cases recently observed by Placzek. In one—a healthy woman of 40 suddenly exclaimed: "I don't know what I am doing," acted strangely, forgot all the occurrences of the last twenty-four hours, with other symptoms of cortical disturbance, coinciding with the appearance of the menses. This condition gradually subsided, until, in the course of twenty-four hours, intense migraine appeared with subjective deafness, photophobia, etc. As the migraine passed off all the other symptoms vanished and they have never been noted since. Another similar case of abrupt change of character in a man subject to severe trigeminal neuralgia confirms the possibility of idiopathic, transient, isolated subdelirium in mentally sound individuals entirely free from any traces of hysteria, epilepsy or alcoholism.

Deutsche Medicinische Wochenschrift (Leipsic), August 9 and 16.

Blood-Pressure and Right-Handedness. A. Hecht and L. Langstein.—Examination of sixty-three young men, mostly soldiers, showed that in 95 per cent. the arterial tension was from 5 to 20 mm. higher on the right side, if the subjects were right-handed, and on the left side if left-handed. In one instance a soldier, naturally left-handed, had learned to use his right hand, but the blood-pressure—higher by 10 mm. on the left side—betrayed his natural propensity. Examination of the blood-pressure may thus afford valuable information in certain criminal cases.

August 16.

Chronic Non-Membranous Diphtheritic Affection. E. Neisser.—Five cases of a chronic affection of the upper air-passages are described, the patients being robust young maidservants or waitresses. The symptoms vanish during the summer, but as cold weather approaches the voice becomes hoarse, the throat dry, the mucous membrane of the nasopharynx atrophied and covered with tenacious mucous and grayish-yellow crusts. In only two cases was there a previous history of diphtheria, but in all the diphtheria bacillus was found constantly, and in almost pure cultures. The syndrome suggests rhinitis fibrinosa, but differs in the site, the absence of any pseudo-membrane and the chronic character. There was nothing to indicate ozena, the accessory cavities were intact. Antidiphtheria serum did not seem to have any influence on the affection. In the patients with antecedent diphtheria the serum possessed marked antitoxic properties, equivalent to 2000 immunization units in one case.

Peculiar Symptom-Picture With a Carcinoma of the Stomach. R. Schuetz.—In the case described, the carcinoma at the pylorus has caused such extensive degeneration of the stomach walls that the organ was reduced to a perpendicular tube about 13 cm. long, its rigid walls practically merely a continuation of the esophagus. The atony of the latter produced slight dilatation above the cardia and temporary stagnation of the contents, but the sound traversed it without difficulty to the pylorus.

Muenchener Medicinische Wochenschrift, August 14.

Coating on the Tongue in Health and Disease. J. Mueller.—*Investigation of the coating on the tongue in health and disease* shows that the organ is most frequently and noticeably coated in acute diseases, whether the digestive apparatus is primarily disordered or not. It is found much less frequently in chronic digestive affections; the proportion in chronic gastritis is *even less than that noted in healthy persons*. The leucocytes are always exceptionally numerous in the scrapings in case of carcinoma of the stomach and also of pulmonary tuberculosis. In all other conditions the coating differs only quantitatively in health and disease. Mueller attributes the increased coating in acute disease to the fact that the tongue is not mechanically cleansed of its thrown-off epithelium, as the patients eat and talk less than normally. Another reason is the desquamative catarrh which accompanies certain diseases. The coating is naturally thicker in persons in whom the *filiform papillæ* are most developed, and is absent on naturally smooth tongues, such as are frequently observed in elderly individuals.

Indications for Surgical Intervention With Ectopic Pregnancy. L. Prochownick.—The early mild or threatening symptoms are no guarantee of the future course of an extrauterine pregnancy. This depends on the location of the ovum, condition of the organ and secondary infection. An extensive experience has impressed Prochownick more and more with the conviction that the best and truest conservatism in these cases lies in early laparotomy. In case of gonorrheal antecedents intervention should be urged, and with even slight indications of temperature in rectum or vagina, all responsibility should be declined unless an operation is allowed. Only with early laparotomy is it possible to count upon restitution of the original conditions.

Suture of Common Carotid. F. Seggel.—An attempt at suicide by a man of 62 resulted in a slanting wound in the common carotid artery, 3 to 4 mm. in length, closed with a clot when received at the clinic an hour later. The artery was compressed with three forceps and three silk stitches taken in the walls, avoiding the intima, strengthened with three others as blood oozed when circulation was restored. The less extensive wound in the vein was also sutured and patient dismissed cured in a month.

Composing on the Typewriter. Seeligmueller.—From the long association of the left half of the brain with the act of writing, some persons find it difficult to write articles requiring much thought on the typewriter. The ideas are accustomed to flow from the left brain out to the pen in the right hand, and efforts to use the left hand on the machine interfere with composition. Seeligmueller counteracts this tendency by first writing out a rough outline of his article with the pen and then elaborating this on the typewriter. In order to concentrate all his attention on his composition, he never punctuates nor uses capitals, but adds these as he revises. It detracts very little from the appearance of the "copy," but adds immensely to the facility of mental composition on the machine.

Therapeutisches Monatsheft (Berlin), August.

Medicinal Treatment of Neurasthenia. Otto Dornbluth.—The writer regards the use of codein in neurasthenia as the greatest progress which the therapy of this affection has yet to record. It has a specific stimulating effect in overcoming morbid drowsiness when patients are compelled to keep continually at work. He has given it in small doses to overworked physicians, teachers, public officials, etc., and all have expressed the utmost gratitude for the relief and stimulating effect, whi[illegible] is not transient like that of the bromids, but lasts and even cures the majority of cases. He commences with .01 gm. three times a day and after four or five days increases to five or six times this amount, continuing with .02 gm. five times a day for four to six weeks, but suspending as improvement is evident. This specific stimulating influence is not due to the sedative effect; morphin and similar anodynes have none of it. He has found it equally effective in cases of psychic depression and melancholia. He considers remedies to improve the condition of the blood an important aid in the treatment of neurasthenia.

Therapie der Gegenwart (Berlin), August.

Influence of Anodynes on Gastric Secretions. F. Riegel.—The various anodynes and analgesics have been employed in gastric affections without much regard to their specific influence on the secretion of gastric juice. Riegel's tests have demonstrated that it is desirable in selecting a drug for the purpose to bear in mind that the belladonna preparations, and especially atropin, check the secretion of gastric juice almost completely, while morphin has exactly the opposite effect. Morphin, therefore, should be given in cases in which no injury is anticipated from considerable increase in the secretion of the gastric juice. On the other hand, when the secretion is already excessive, as is usual with ulcus, morphin is contraindicated, and one of the belladonna preparations will be found useful to diminish the over-secretion in addition to its analgesic effect.

Treatment of Ozena. F. Klemperer.—The base of all treatment of ozena is to keep the nasal passages absolutely clean. This deprives the affection of its chief evil features and is the only means of cure. Tepid salt solution is a good cleansing fluid. It is best applied with a nose pump, combined with preceding tamponing for an hour or so, and all night for each nostril in turn. The nose should be rinsed three times a day.

Cataplasms in Gonorrheal Joint Affection. A. Freudenberg.—*The benefits attained in gonorrheal arthritis and tendovaginitis with hot cataplasms* frequently renewed day and night, are extolled by Freudenberg, after eight years of experience, as truly remarkable. They obviate all danger of the ankylosis which is so common and early in these cases. He applies them to encircle the entire joint and extend several inches above and below. He has never seen any benefit from cold applications and has witnessed direct harm result from immobilization. He even treats gonorrheal prostatitis in the same way, with hot cataplasms to the perineum. In case of gonorrheal epididymitis, he commences with the ice-bag, changing to suspension and compresses of lead water, then to the Priesnitz, and then to the hot cataplasms. He has observed that too prolonged use of cold applications is apt to leave extensive indurations in the epididymis.

Gazzetta degli Ospedale (Milan), August 5 and 12.

Antidiphtheria Serum in Pertussis. R. Indica.—In seven cases of severe whooping-cough an injection of 10 c.c. of antidiphtheria serum had a marked effect in ameliorating and abbreviating the disease. The effect is similar to that obtained in diphtheria; the resisting powers of the organism are evidently increased.

August 12.

Surgery of the Cerebral Ventricles. A. Montini.—A child 3 years of age presented a typical case of chronic hydrocephalus and progressive idiocy with frequent convulsions, the parents and other children being robust. Montini trephined and drained the ventricle, removing 350 gm. of cerebrospinal fluid. The child had a violent convulsion and sank into coma, but after artificial respiration and other measures had been employed the benefits of the intervention were soon apparent in the complete cessation of the convulsions and convergent strabismus and control of the simple and co-ordinated movements.

Disarticulation of the Hip. E. Dominici.—The method proposed by Dominici, which he has found a great improvement over other methods of disarticulating [illegible] hip-joint, is to make a longi[illegible] incision above the [illegible]hanter down to the bone, [illegible]ting the [illegible] possible. The head [illegible] sli[illegible] bulum, passed out through the incision by twisting the limb and held in that position by an assistant. The soft parts are thus left without any bone and a strong elastic ligature is passed around them under the protruding bone. The limb is then amputated as required and the vessels ligated separately. The shoulder is treated in a similar way.

Vratch (St. Petersburg), July 8.

Plant Extracts React to Florence Sperm Test. D. L. Davidoff.—The substance in human semen which produces the characteristic reaction in the Florence test exists also in numerous plants, as similar crystals are produced by the action of the Florence reagent on aqueous extracts and also on the pollen and anthers of certain plants. The list Davidoff has tested is a long one and includes the chrysanthemum, hyacinth and varieties of tulips, with numerous dried medicinal herbs and the male flower of the maple. A drop of any of their extracts or infusions will simulate a drop of human spermatic fluid in its reaction to the Florence test, and he warns medical experts of the possibility of error from this cause in their deductions. Mistakes are especially liable to occur with homemade infusions of chamomile, elder and secale, which are in such common use, and in his experiments responded typically to the Florence reaction after having been dried on a cloth for two months. He also states that the cholin crystals obtained with silver oxid from the blossoms of the taraxacum, elder, etc., were more abundant and more characteristic than those derived from the yolk of an egg with either ether, alcohol, platinum chlorid or silver oxid.

Renal Lithiasis Cured with Uresin. I. B. Kudinzeff. Uresin or urotropinum dilithiocitricum has been unfailingly successful in the treatment of kidney gravel in Kudinzeff's experience. It not only abolishes the gravel and with it the irritation of the urinary passages, but also reduces the amount of uric acid in the urine and alters the elements that have been the factors in the production of the calculi. Relief is promptly evident after its administration and he has never had any cause for regretting its use in any way, but is becoming more and more impressed with its value the wider his experience. It is a combination of urotropin, lithium and citric acid.

Change of Address.

B. A Becker, 2612 W. Main St., Louisville, Ky., to Silver Lake, Wis.
Carl Booth, Carlow, to Barnes Medical College, St. Louis, Mo.
C. J. Beise, Tracy to Fergus Falls. Minn.
S. Brownstein, 16 Johnson, to 374 S. Halsted St., Chicago.

H. M. Williams, Oklahoma City, to Cushing, O. T.

Queries and Minor Notes.

THE HIPPOCRATIC OATH.

Baltimore, Md., Aug. 5, 1900.

To the Editor:—Will you inform me if you can supply me with a copy of the "Hippocratic Oath?" If so, please give price and description of same; if you have not a copy, kindly inform me of some place where I can get it. Yours truly, C. K. Y.

Ans.—The "Hippocratic Oath" has been published many times; it is given in full in Dunglison's Practitioner's Ready Reference Book, and in several encyclopedias. It is too long to reproduce here.

MEDICAL LAWS.

Oneida, Tenn., Aug. 19, 1900.

To the Editor:—Will you kindly give me the laws regulating the practice of medicine in Indiana, regarding state boards and graduates from a three-year school? Very respectfully, J. A. S.

Ans.—Applicants for license to practice medicine in Indiana must be *bona fide* residents of the county and state, must procure the necessary application blank from the county clerk, which, properly filled, with the diploma and a fee of $10, must be sent to the State Board of Medical Registration, Room 120, State House, Indianapolis. If satisfactory, the Board will issue its certificate, which, on presentation to the county clerk, will entitle the applicant to a license. If not satisfactory an examination must be passed, the fee for which is $25. The Board has recently passed a resolution "that no applicant from any other state for a certificate shall be granted one on conditions more lenient than those required of applicants from Indiana by the examining board of the state from which he comes." An applicant from Tennessee would, therefore, probably have to pass an examination. For further particulars, address Dr. W. F. Curryer, Secretary of the State Board of Registration, Indianapolis, Ind.

New York, Aug. 28, 1900.

To the Editor:—Kindly inform me of the laws in regard to the practice of medicine in the states of Wisconsin and Michigan. Yours truly, M. A.

Ans.—The essential points in the medical practice law of Wisconsin were given in The Journal of April 7, p. 893, and those of Michigan in the number of July 28, p. 265. The inquirer is referred to these issues.

RED CROSS MEDICAL ASSOCIATION.

Peoria, Ill., Aug. 25, 1900.

To the Editor:—Will you please inform me as to what you know concerning the Red Cross Medical Association? What success have they had in the East? You will do me a great favor if you answer at once. Yours, E. H.

Ans.—As we understand our correspondent's question, he refers to an organization designed to supply medical attendance to subscribers. From looking it up it appears to us to be simply lodge practice, and The Journal has repeatedly expressed its editorial opinion against this. So far as we know, the organization has not extended very far in any part of the country, and we should hope it will not become popular, as it seems to us merely a scheme for making money out of the medical profession. Our knowledge is confined to newspaper articles and one or two of its circulars.

LITERATURE ON DIETETICS AND HYDROTHERAPY.

Bodie, Cal., Aug. 11, 1900.

To the Editor:—Will you kindly inform me of a good work or magazine on dietetic literature and hydrotherapy? Sincerely, J. E. C.

Ans.—We do not at present recall any prominent work or magazine specially devoted to these two subjects alone. There are several journals devoted more or less to dietetics, some of them advocates of fads. There are none that we could specially recommend in all respects.

KNAPP'S ARCHIVES OF OTOLOGY.

New Washington, Ohio, Aug. 27, 1900.

To the Editor:—Please inform me where *Knapp's Archives of Otology* is published, and price of same. Very truly, A. E. L.

Ans.—*Knapp's Archives of Otology* is published by G. P. Putnam's Sons, 27 and 29 W. 23rd St., New York, price, $4 per year.

HOSPITAL CONSTRUCTION.

Shreveport, La., Aug. 20, 1900.

To the Editor:—Please recommend to me some of the standard works on "The buildings, constructions, arrangements and maintenance of hospitals," and oblige, J. A. S.

Ans.—We do not know of any recent general work on the subject published in this country. Burdett's Hospital Annual, which goes under this name, though the title varies, is perhaps the best general manual. Burdett's Hospitals and Asylums of the World, 4 vols., London, J. and A. Churchill, 1891, is a large and expensive work. The volume of essays, published by the Johns Hopkins Hospital some twenty years ago may also be referred to. We refer the inquirer also to an article by Dr. McDill, in The Journal of January 21, 1899.

CLEANLINESS OF BARBERS' INSTRUMENTS.

Ishpeming, Mich., Aug. 29, 1900.

To the Editor:—I think I have seen in The Journal lately, but I can not say where, some articles on the subject of cleanliness of instruments, etc., of barbers. If you can tell me where I can find anything on the subject I would be much obliged. Very truly yours,
T. A. F.

Ans.—We have not published any articles recently on the subject you mention, but we have editorially noticed the subject during the past year or two. You will find articles, notably one by A. W. Suiter, of Herkimer, N. Y., in the Proceedings of the American Public Health Association. His article was read in 1897 and has probably excited as much interest as any, though it is a short one. There have been laws regarding the barber trade passed in several states, Minnesota, Nebraska and Missouri, for example, and possibly others. Dr. Suiter's article was abstracted in the Proceedings of the Public Health Association in volume xxix, p. 1070, of The Journal, Nov. 20, 1897.

GLANDULAR TREATMENT OF HAY FEVER.

La Harpe, Ill., Aug. 29, 1900.

To the Editor:—Will you please tell me where I can get any literature on the treatment of hay-fever by the thyroid or suprarenal extracts? Have you any reprints of Dr. Beaman Douglas on this subject? Yours truly,
J. C. A.

Ans.—The literature on suprarenal extract is comparatively recent. The inquirer is referred to a paper of Dr. Bates in The Journal of August 11, and to that of Dr. Murphy in the *Lancet-Clinic* of April 7 (abstracted in The Journal of April 21, p. 993); of Dr. Aldrich, *Medical Standard* September, 1899 (abstracted in The Journal of Sept. 23, p. 786); of Dr. Bulette, *Denver Medical Times*, November, 1899 (abstracted in The Journal of Nov. 25, p. 1349), etc. Dr. Beaman Douglas' paper, also abstracted in The Journal of Sept. 9, 1899, p. 660, was published in the *New York Medical Journal* of Sept. 2, 1899. It may be that a reprint can be obtained by application directly to the author. See also our advertising pages.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., August 8 to 21, 1900, inclusive:

George F. Adair, acting asst.-surgeon, now at Fort Sheridan, Ill., to report to the commanding officer of that post for duty with the 5th Infantry, under orders for foreign service.

W. Edson Apple, acting asst.-surgeon, leave of absence granted, on the expiration of which he will report at San Francisco, Cal., for duty with troops for foreign service.

Orlando Ducher, major and surgeon, Vols., former orders amended so as to direct him on expiry of his present leave of absence to report by letter to the Surgeon-General.

Harry C. Gemmill, acting asst.-surgeon, from Fort Thomas, Ky., to accompany the 2d Infantry, under orders for foreign service.

J. Randolph Harmer, acting asst.-surgeon, from Washington, D. C., to Fort Fremont, S. C., for post duty.

Philip F. Harvey, major and surgeon, U. S. Army, from the Presidio of San Francisco, Cal., to Nagasaki, Japan, to establish a base hospital at that place.

John Van R. Hoff, major and surgeon, U. S. Army, to proceed without delay to Taku, China, and report in person to Major-General Adna R. Chaffee, U. S. Vols., for duty as chief surgeon on his staff.

Alvis B. Kennedy, acting asst.-surgeon, former orders directing him to proceed to San Francisco, Cal., to accompany troops on foreign service revoked.

Thomas J. Kirkpatrick, Jr., lieutenant and asst.-surgeon, U. S. Army, member of a board at Washington Barracks, D. C., to examine candidates for appointment as second-lieutenants in the Army.

Edward E. Lambkin, acting asst.-surgeon, previous orders amended so as to direct him to proceed from Baltimore, Md., instead of from St. Louis, Mo., to the Department of California.

Edward L. Munson, captain and asst.-surgeon, U. S. Army, member of a board at Washington Barracks, D. C., to examine candidates for appointment as second-lieutenants in the Army.

Arthur B. Smith, acting asst.-surgeon, from San Francisco, Cal., to the U. S. General Hospital, Fort Bayard, N. M., for temporary duty.

Bat Smith, acting asst.-surgeon, now at Fort Sheridan, Ill., to proceed to Wharton, Tex., for annulment of contract.

Benjamin B. Warriner, acting asst.-surgeon, from Fort Fremont, S. C., to San Francisco, Cal., for duty with troops going on foreign service.

James A. Alexander, acting asst.-surgeon, leave of absence granted.

Irvin E. Bennett, acting asst.-surgeon, from duty in the Department of Porto Rico to San Francisco, Cal., for duty with troops en route for China.

George M. Bradfield, acting asst.-surgeon, from Fort Ontario, N. Y., to Philadelphia, Pa., for annulment of contract.

Ira C. Brown, major and surgeon, Vols., leave of absence extended.

Edward T. Comegys, major and surgeon, U. S. Army, from San Francisco, Cal., to Nagasaki, Japan, as medical supply officer at that place.

Alfred C. Godfrey, acting asst.-surgeon, from Fort Washakie, Wyo., to San Francisco, Cal., for duty with troops destined for foreign service.

Guy C. M. Godfrey, captain and asst.-surgeon, U. S. Army, previous orders directing him to report for duty in the Philippines suspended.

Lewis A. Griffith, lieutenant and asst.-surgeon, 42d Infantry, Vols., having tendered his resignation is discharged from the service of the U. S., to take effect August 20, 1900.

Charles W. Hack, acting asst.-surgeon, from the Department of Dakota to duty at Columbus Barracks, Ohio.

Aubray F. Higgins, acting asst.-surgeon, from the Department of California to duty with troops going on foreign service.

Herbert M. McConathy, acting asst.-surgeon, from duty in the Department of Porto Rico to Washington Barracks, D. C., for duty with Battery M, 7th Artillery, en route to San Francisco, Cal., for foreign service.

Henry E. Menage, acting asst.-surgeon, previous orders amended so as to require him to proceed from New Orleans, La., to Fort Wingate, N. M., for duty.

Charles B. Nichols, acting asst.-surgeon, from Fort Wingate, N. M., to San Francisco, Cal., for duty with troops going on foreign service.

Auguste A. Nonel, acting asst.-surgeon, from Fort Leavenworth, Kan., to New York City, N. Y., for annulment of contract.

Lieven de Poorter, acting asst.-surgeon, now in New York City, N. Y., on expiry of his leave of absence to proceed to New Orleans, La., for annulment of contract.

Benjamin F. Pope, lieutenant-colonel and deputy surgeon-general, U. S. Army, and Samuel O. L. Potter, major and surgeon, Vols., members of a board convened in San Francisco, Cal., to examine candidates for appointment as second-lieutenants in the Army.

Dwight C. Powell, acting asst.-surgeon, from Logansport, Ind., to Fort Thomas, Ky., for duty with the battalion of the 2d Infantry, under orders for foreign service.

James F. Presnell, acting asst.-surgeon, now at Fort Leavenworth, Kan., for duty with the 1st Infantry, under orders for foreign service.

Merton A. Probert, acting asst.-surgeon, from Constantia to Columbus Barracks, Ohio, for temporary duty.

Willis J. Raynor, acting asst.-surgeon, from Denver, Colo., to Fort Washakie, Wyo., for post duty.

M. A. Rebert, acting asst.-surgeon, leave of absence granted.

William E. Richards, lieutenant and asst.-surgeon, U. S. Army, from the Department of Porto Rico to post duty at Plattsburg Barracks, N. Y.; a subsequent order sends him instead to Fort Ontario, N. Y.

Henry A. Shaw, captain and asst.-surgeon, U. S. Army, from the General Hospital at San Francisco, Cal., to Nagasaki, Japan, for duty at the general hospital to be established there.

W. I. Tanner, acting asst.-surgeon, leave of absence granted.

Dwight B. Taylor, acting asst.-surgeon, from Columbus Barracks, Ohio, to Fort Thomas, Ky., to accompany troops to San Francisco, Cal., returning thereafter to his proper station.

Albert E. Truby, lieutenant and asst.-surgeon, U. S. Army, former orders amended so as to grant leave of absence, on the expiration of which he will proceed from New York City to Havana, Cuba, for assignment in the Division of Cuba.

The following acting asst.-surgeons to proceed from the places designated to San Francisco, Cal., for assignment to duty with troops destined for foreign service: Howard H. Bailey, Washington, D. C.; Louis Brechemin, Jr., Philadelphia, Pa.; William C. Mabry, Cleveland, Ohio; Clemens W. McMillan St. Louis, Mo.; Robert E. Noble, New York City, N. Y.; Lorin B. Ohlinger, Alleghany, Pa.; Joseph A. O'Neill, New York City, N. Y.; Luke B. Peck, Brookline, Mass.; John A. Rafter, West Winfield, N. Y.; William Roberts, Washington, D. C.; J. Ralph Shook, Greencastle, Pa.; Charles A. Sturtevant, West Somerville, Mass.; Henry J. Watson, Ottumwa, Iowa; George Wilklow, Ellenville, N. Y.; John D. Brooks, Washington, D. C.; William E. Cass, St. Louis, Mo.; L. d'Orville Chabut, Youngstown, Ohio.; George R. Clayton, Nevada, Iowa; William J. Condon, Jamesburg, N. J.; Harry A. Cossitt, Morris Plains, N. J.; U. S. Grant Deaton, Thackery, Ohio; Paul R. Fletcher, St. Louis, Mo.; Jacob F. Hadley, Passaic, N. J.; A. Bruce Henderson, Batavia, Mich.; Gustavus I. Hogue, North Lake, Wis.; William V. Kellogg, Detroit, Mich.; Frederick A. Lewis, Walworth, N. Y.; Howard D. Lewis, Baltimore, Md.; James I. Mabee, Rockwood, Mich.; Robert C. Macy, Mobile, Ala.; R. Boyd Miller, Lamar, Mo.; George S. Mintzner, Philadelphia, Pa.; Edwin W. Patterson, Washington, D. C.; Louis J. Perkins, Pendleton, Ore.; Willard D. Preston, Attica, N. Y.; James A. Rabbett, Elkins, W. Va.; George A. Renn, Raleigh, N. C.; James C. Rutledge, Detroit, Mich.; Charles F. Sanborn, Willard, N. Y.; C. Edward Sears, Salem, Va.; Joseph F. Siler, New York City, N. Y.; Calvin D. Snyder, Baltimore, Md.; Lewis H. Wheeler, Westport, Conn.; William A. Wickline, Warm Springs, Mont.

New Patents.

Changes in the Medical Corps of the U. S. Navy for the week ending Aug. 25, 1900.

P. A. Surgeon L. L. Von Wedekind, ordered to temporary duty at the headquarters of the Marine Corps, Washington, D. C., August 22, and then to the *Richmond*

Medical Inspector J. R. Waggener, transferred from the naval hospital, Cavite, P. I., to the naval hospital, Yokohama, Japan, for treatment.

Surgeon G. Pickrell, detached from the naval hospital, Yokohama, Japan, and ordered to the Cavite Naval Station.

Surgeon O. D. Norton, detached from the *Monocacy* and ordered to duty with the marine regiment in China.

Pharmacist S. W. Douglass detached from the *Massasoit* and ordered to the Key West Naval Station immediately.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the United States Marine-Hospital Service for the seven days ending *Aug. 23, 1900:*

Surgeon George Purviance, to report at Washington, D. C., for special temporary duty; thence to proceed to Baltimore Quarantine Station as inspector.

Surgeon H. R. Carter, granted leave of absence for twenty days from Aug. 24.

Surgeon J. H. White, to proceed to Baltimore Station as inspector.

Surgeon W. P. McIntosh, granted leave of absence for seven days.

Asst.-Surgeon A. R. Thomas, granted leave of absence for one month from Sept. 15.

Asst.-Surgeon L. E. Cofer, granted leave of absence for one month and ten days from Sept. 21.

Acting Asst.-Surgeon B. J. Brown, granted leave of absence for fourteen days from Aug. 12.

Acting Asst.-Surgeon W. W. McKay, granted leave of absence for four days.

Acting Asst.-Surgeon Lee W. Staton, granted leave of absence for ten days from Aug. 12.

Hospital Steward J. V. LaGrange, granted leave of absence for ten days from Sept. 11.

APPOINTMENT.

George A. Morris, of Michigan, appointed junior hospital steward Aug. 15, 1900.

Health Reports.

The following cases of smallpox yellow fever, cholera, and plague, have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended Aug. 25, 1900:

SMALLPOX—UNITED STATES.

Alaska: Cape Nome, Aug. 18, 6 cases.

California: Oakland, July 7-14, 2 cases.

Kansas: Wichita, Aug. 11-18, 2 cases.

Louisiana: New Orleans, Aug. 11-18, 5 cases, 7 deaths.

Massachusetts: Lowell, Aug. 11-18, 2 cases.

Minnesota: Minneapolis, Aug. 11-18, 2 cases; Winona, Aug. 7-21, 7 cases.

New York: New York, Aug. 11-18, 1 case.

Ohio: Cincinnati, Aug. 10-17, 5 cases; Cleveland, Aug. 11-18, 12 cases; Dayton, Aug. 11-18, 6 cases; Portsmouth, Aug. 11-18, 1 case.

Utah: Salt Lake City, Aug. 11-18, 1 case.

Washington: Tacoma, Aug. 4-11, 1 case.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, June 30-July 13, 13 deaths.

Costa Rica: Port Limon, Aug. 8, 1 case.

England: Liverpool, July 31-Aug. 4, 7 cases; London, July 21-Aug. 4, 18 cases.

France: Lyons, July 22-29, 1 case; Paris, July 14-Aug. 4, 5 deaths.

India: Bombay, July 10-24, 11 deaths; Calcutta, July 7-21, 26 deaths.

Malta: June 16-30, 11 cases, 1 death.

Mexico: City of Mexico, Aug. 5-12, 3 cases, 3 deaths; Vera Cruz, Aug. 4-11, 1 death.

Russia: Moscow, July 21-28, 2 cases.

Spain: Madrid, June 30-July 28, 77 deaths.

Straits Settlements: Singapore, June 30-July 7, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, June 30-July 13, 13 deaths.

Cuba: Cienfuegos, Aug. 17, 1 case.

Colombia: Bocas del Toro, July 20-Aug. 3, 4 cases, 2 deaths; Panama, Aug. 6-13, 3 cases, 1 death.

France: Havre, Aug. 9, on Steamship *Caravalles*, from Senegal, Africa, 1 case.

CHOLERA.

India: Bombay, July 10-17, 239 deaths; Calcutta, July 7-21, 105 deaths; Madras, July 14-20, 3 deaths.

Japan: Osaka and Hiogo, July 21-28, 1 case, 1 death; Yokohama, July 7-28, 2 cases, 2 deaths.

PLAGUE.

Australia: Sydney, June 30-July 14, 4 cases.

Brazil: Rio de Janeiro, June 30-July 13, 74 cases, 31 deaths.

India: Bombay, July 10-17, 60 deaths; Calcutta, July 7-21, 107 deaths.

Japan: Formosa, June 21-July 12, 82 cases, 63 deaths.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may *be referred to it by the Association or either of the Sections,* unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

INFANTILE CEREBRAL PALSY.

CLASSIFICATION OF TWENTY-FIVE CASES, WITH ILLUSTRATIONS.*

A. C. COTTON, A.M., M.D.
CHICAGO.

Under infantile cerebral palsy I would include all conditions of impaired function due to cerebral lesion, even if the only symptom be mental deficiency or epilepsy. It will be seen that an extremely wide range of disorders will thus be brought into one clinical group, which would include the restricted congenital spastic rigidity of Little; the cerebral type of hereditary spastic paraplegias described by Frend, Erb, Sachs and others, as well as the lighter forms in which but slight evidence of any paresis is to be discovered at the time of examination.

The following twenty-five cases—save one—are selected from my clinical records of the past year, as fairly illustrative of the majority of the commoner types of infantile palsy:

Case 1.—Edith N., aged 10 years. Family history negative. Patient is the eldest of four children, all the others being normal. Labor lasted twelve hours. No instruments were used. Mother's health was not as good as usual during pregnancy.

Up to the age of four months nothing unusual was noticed, excepting that she was very irritable. Eruption of teeth began at four months, when she had a severe convulsion, lasting from ten to fifteen minutes. Since then there have been frequent repetitions, at times two to four daily.

When about a year old she began to use a few words, but these were soon dropped and there has been no further acquirement of speech. She had never stood alone and could not sit nor support her head. Intelligence *nil*. Had to be cared for as an infant.

The head measured 19 inches; the eyes reacted to light and accommodation; the mouth was kept open; the lips were thick; the upper jaw was prominent, and the teeth projecting. The thyroid was enlarged; the chest emaciated; there was flaring of ribs, and scoliosis. Organs and abdomen were negative. The contractures of hands and arms were imperfectly overcome by slow exercise of force; the skin was cold and cyanotic; the legs were contracted at hips and knees, the right being always crossed over the left.

Case 2.—Clara H., aged 10 years. Family history negative. Labor normal, of twenty-four hours duration. No instruments were used. Birth weight, four pounds. In infancy it was noted that she never used arms or legs. At 1½ years she had a convulsion, which had been repeated at varying periods, often monthly. They had increased in intensity; always occurring at night. Contractures of limbs were noticed at about 2 years. Had never sat, walked, or talked. Seemed to understand the most of what was said to her. Had control of sphincters and could indicate when she needed to evacuate bladder or bowels.

The head measured 19 inches; strabismus; the mouth was kept open; the tongue protruding, and saliva escaping; the thyroid was not palpable; contractures at the elbows, wrists, and fingers, also at the hips and knees and left scoliosis; there was deep depression at the sternum; viscera normal; extremities cold and emaciated, and reflexes exaggerated.

Case 3.—Valeria D., aged 5 years. Family history negative. Labor lasted thirty-six hours, forceps being used late in the case. Had a continuous spasm for three days; since then there have been many recurrences of convulsions, usually apparently due to some indigestion.

The head measured 19½ inches; the expression idiotic; the mouth open; continuous drooling; a high arched palate; diplegia; marked spasticity in lower extremities, less in upper; thyroid slightly enlarged; when excited there was an odd tremor of the lower jaw; repeats a few easy, short words; unable to walk, sit, or even support head; has always had to be fed and has difficulty in deglutition; idiotic.

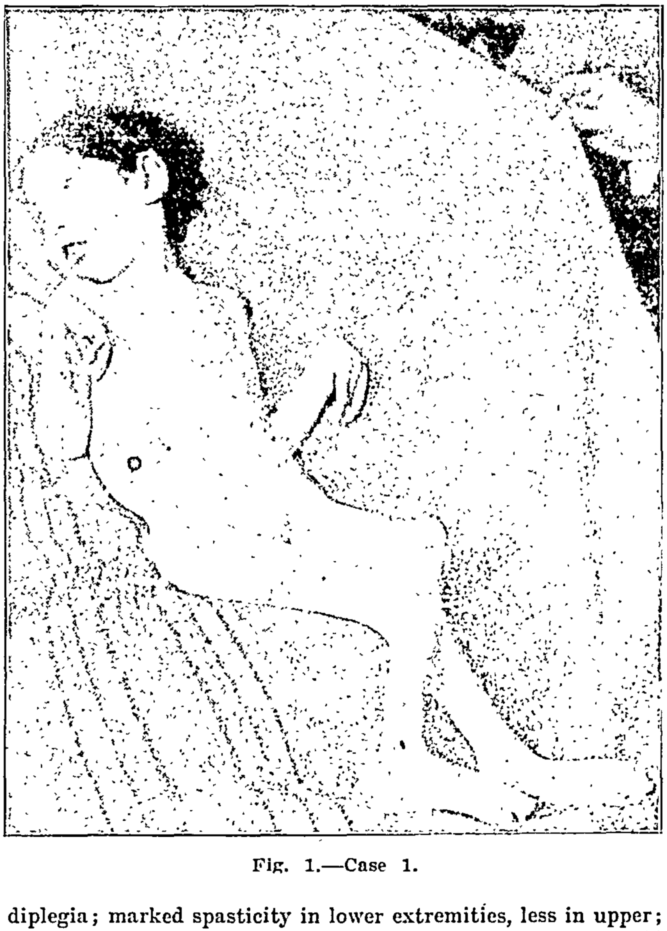

Fig. 1.—Case 1.

Case 4.—Maud B., aged 3 years. Difficult labor; premature at eight months. Strabismus, athetosis, diplegia, rigidity, contractures, mental impairment, microcephalic, and without speech. Has never had convulsions.

Case 5.—Mattie K., aged 10 years. There had been four other children, all of whom are dead. The first pregnancy resulted in twins, who were born after a labor of five days.

---

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Both died during the first day of life. A still birth followed. This patient was born after the third gestation, and since there has been another child who only lived twelve hours. At birth patient was too weak to nurse, and is said to have weighed two and one-half pounds. The labor was difficult, forceps finally being used. Infant was comatose one hour and a half after birth. It was noticed as early as three weeks that if startled she would hold her breath until deeply cyanosed. This has not occurred since the age of 2 years. She recognized mother at 8 months; eruption of teeth took place at 12 months; talked at 24 months; walked at 40 months. There has been a tendency to reaction of the head since birth. Always easily frightened.

The head measured 19¾ inches. Strabismus. Articulation slow and indistinct, accompanied by contortions of body and limbs; reflexes exaggerated; slight contractures of both upper and lower limbs; the hands, fingers, and, to less degree, the toes, show athetoid movements; besides these there are present choreiform movements of whole body. nearly constant; said to *be as bright as any child of her age; fond of music,* and is able to assist in housework.

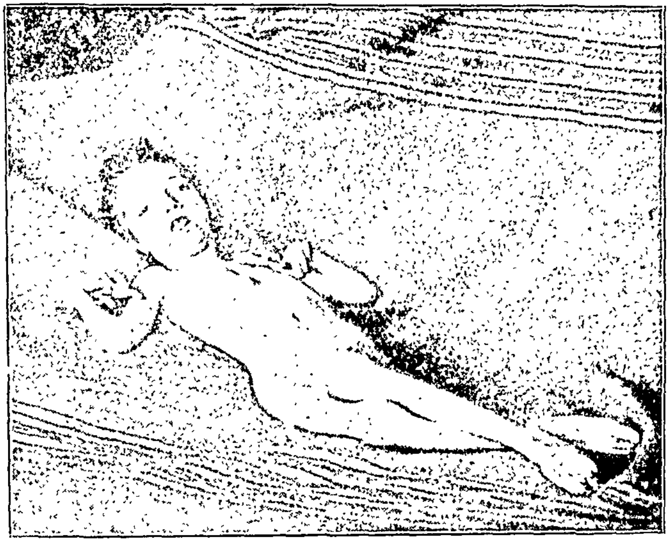

Fig. 2.—Case 2.

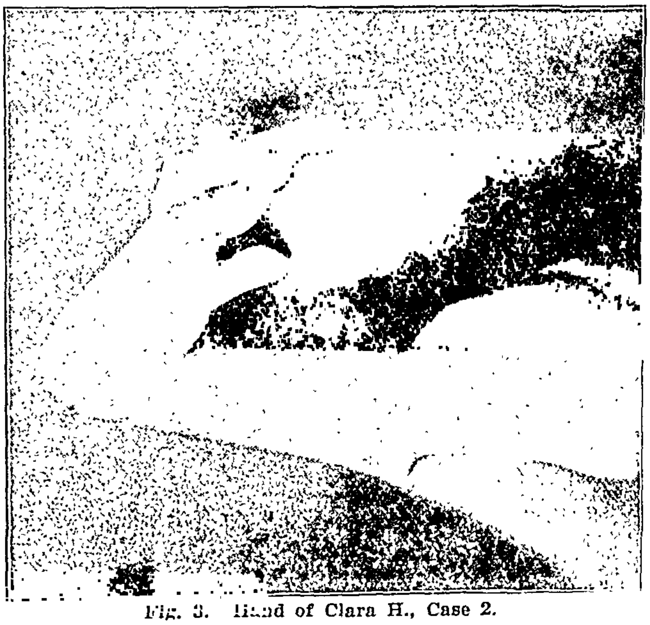

Fig. 3. Hand of Clara H., Case 2.

Case 6.—Clara H., aged 4 years. There are two other children living and normal. During gestation her mother had pneumonia and did not recover strength the whole term. Parturition was easy. Weight at birth, five pounds, and she seemed very weak; breast fed; dentition normal. Did not walk alone until 3 years of age; also slow about talking. Well developed; voice husky; speech slow; chest and abdomen negative; appetite good, and bowels regular. No incontinence of urine or feces. Gait uncertain and staggering, knees touching, but feet far apart; tendency to fall backward. If running, is unable to stop quickly; inco-ordination of upper limbs; impossible to detect condition of reflexes.

Case 7.—Dora S., aged 3 years. Four other children, all living and well. Development normal until 1 year old, when she fell down stairs, striking on back of head. Six months after this fall she stopped walking, and now can not stand or sit alone; is not able to hold up head unsupported. The head measures 22½ inches; the fontanel open; no protrusion of the eyeballs; the chest and abdomen negative; mental condition nearly normal; reflexes exaggerated; uses a few articulate sounds.

Case 8.—Florence H., aged 11 years. Both parents living and well. The history of pregnancies of the mother is: 1, twelve hours' labor, child living and normal; 2, three days' labor, stillbirth; 3 and 4, miscarriages; 5, six hours' labor, Florence, "blue," and did not become red for twenty-four hours; 6, miscarriage; 7, six hours' labor, child an epileptic.

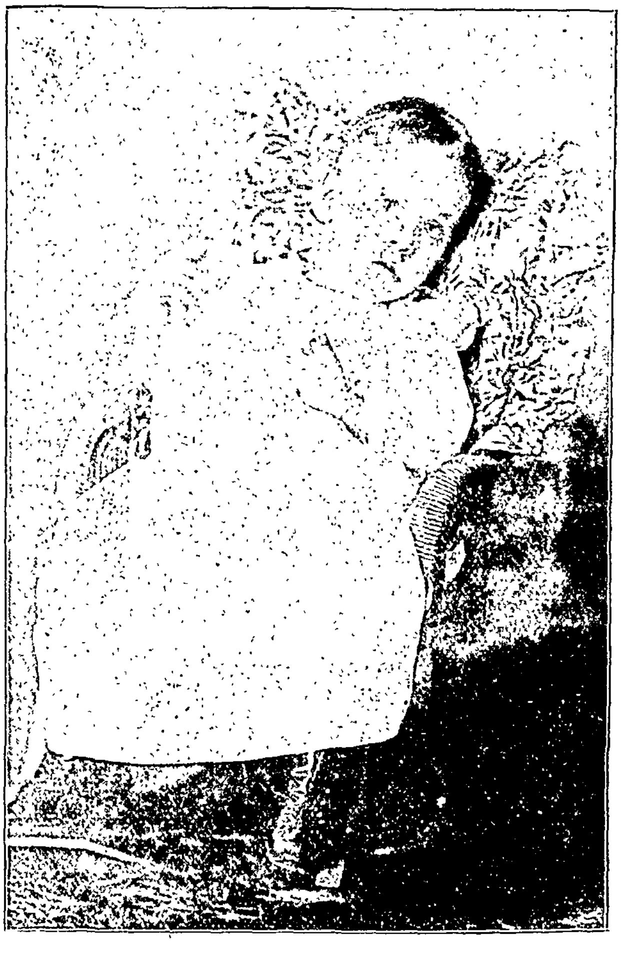

Fig. 4.—Case 4.

At 18 months had convulsions for half a day, and recurrences every three months or oftener, up to the 7th year. At 5 years she had a convulsion which lasted twelve hours; afterward could not use right arm for two months. She did not stand for a week, and then dragged right foot in walking. At 7 years she had a very severe, prolonged attack, which involved both sides—all previous attacks had affected the right side only. Following this there was paralysis for three months, and she did not speak for four months. Has not had a spasm since the one at 7 years of age. The head measured 20½ inches; the child now speaks as one of 2 years would do.

Case 9.—B. L., aged 8 years. One of a family of seven children, of whom four are living. A prolonged labor, forceps being finally used; asphyxiated three hours: recurring spasms the first five days of life: none since. The head was *normal* in size; right hemiplegia; a marked intention tremor in both arms; no nystagmus; the speech is slow, monotonous and indistinct; the voice husky, and uses very few words; mental impairment; the gait is uncertain, with tendency to cross-legged progression.

CASE 10.—Giovanni S. Labor normal. Birth weight said to be fourteen pounds. Eruption of first tooth at 3 months, when he was very restless, had fever, rolled head from side to side and the eyes became crossed. Was ill for two months, at end of which time he cut a second tooth. After this he seemed better generally, but strabismus continued and he made no effort to use left arm or leg. Thumb of that hand is so tightly adducted that it was necessary to interpose cotton to prevent maceration of skin. Each time he cut a tooth he had a return of nervous symptoms. Has never had any other illness. The head is symmetrical and measured 18⅞ inches. Ptosis of both upper eyelids, and partial paralysis of muscles of face. Strabismus and left hemiplegia; slight spasticity.

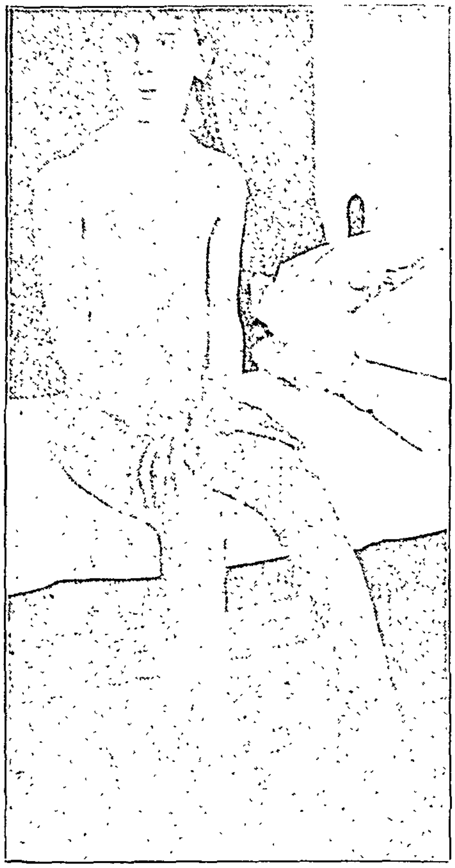

Fig. 5.—Case 5.

CASE 11.—Lillie B., aged 6 years. The youngest of three children, the others being normal, mentally and physically. Labor was normal; delicate and did not walk until 4 years of age. The mother can not tell when the difference in the two sides was first noticed; never had convulsions. The head was undersized, measured 19 inches, expression idiotic, strabismus; mouth open the greater part of the time; did not talk; was very restless, in almost constant motion, and frequently laughed immoderately; right hemiplegia more marked in upper extremity; walked and ran around, but dragged right foot; had no control of bladder or bowels; fond of music; had a habit of biting forefinger of right hand.

CASE 12.—Edith C., aged 3 years. Both parents undersized and the father shows many stigmata of degeneration, viz., small head, projecting upper jaw with irregular teeth; lower jaw receding; high palate; voice high and falsetto. No history of specific infection. An older child died at 6 months of some cerebral trouble. Patient had an attack of meningitis with convulsions during the first year. When seen a right hemiplegia was discovered, but the exact date of its onset it has not been possible to secure. She had no teeth; did not walk or talk at 1 year of age; has had frequent digestive disturbances, with fever, constipation, and vomiting. Insomnia, irritability, and restlessness marked at times; has never walked or stood alone; only uses four or five words; picture showed large, misshapen head; ptosis of left eye; partial paralysis of face; right hemiplegia, and deficient mental development.

CASE 13.—Della S., aged 8 years. Mother healthy; father for past seven years had had "spinal disease," probably locomotor ataxia. Patient was healthy up to two years of age. At that time she was struck on the head, producing a wound that bled freely. Two weeks after injury, while nursing, she suddenly stiffened and began to twitch limbs. This continued for a short time, then the muscles relaxed, though she did not regain consciousness, and spasms were repeated at intervals of five hours. The following day she seemed fully recovered. Two or three weeks later she had a similar attack, followed by coma, lasting through the whole night. For the next six months she seemed quite well; talked, walked, played, etc., and at 2 years of age she had learned to speak some English and German. When 2½ years old she had a severe convulsion, perfect relaxation not coming for four hours. Following this she did not seem to notice anything; did not talk; one side of face was drawn, and right side of body and limbs were paralyzed. Six weeks later she began to walk and to use her arm. The leg gradually improved, as did the face, but the arm and hand have shown less improvement. Complete aphasia lasted for three years. She has acquired a limited vocabulary since, but this is wholly in English. Since the severe convulsions of 2½ years there had been no [illegible] ago when she began to have "spells;" [illegible] to her mother as if frightened, stared [illegible]

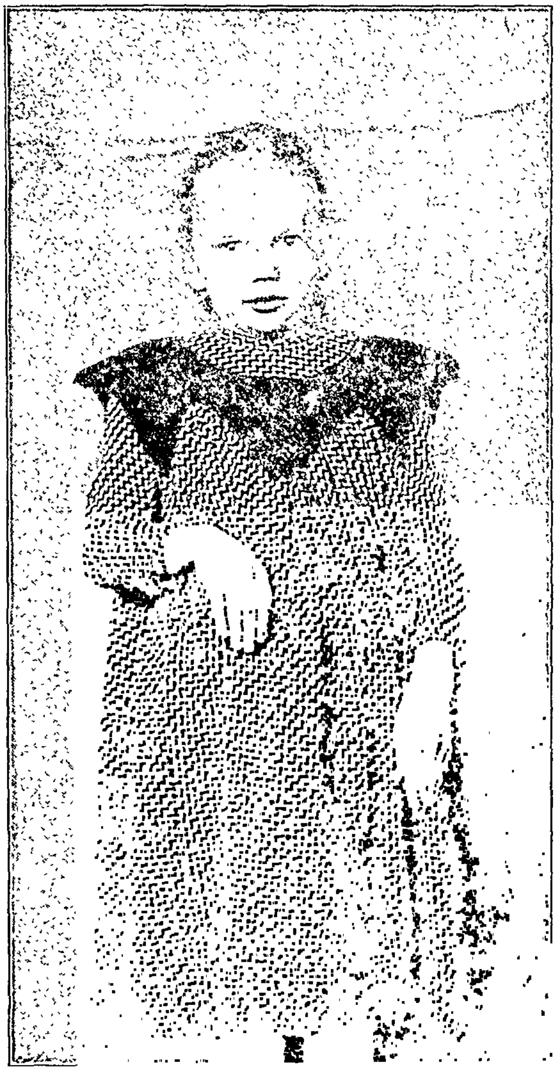

Fig. 6.—Case 8.

of twitch muscles. These lasted only a minute or two, but were frequent, sometimes daily.

CASE 14.—Herbert C., aged 25 years. Family history negative. Well up to 6 months of age, at which time he had an attack of meningitis, during which he had several convulsions. He lay in a semi-comatose condition for several days and recovery was not looked for. Following this there was a right hemiplegia, with strabismus. Did not walk alone until 5 years of age. By the aid of braces and walking machines he learned to walk, for a considerable time with a staggering, uncertain gait. He was slow also in learning to talk, enunciation being difficult and indistinct. Was generally good-natured. When 12 years of age he was sent to Lincoln to the school for feeble-minded. He attended two years and made great improvement, learning the use of paretic hand and arm so as to be able to use musical instruments and tools in gardening. The body developed, but right side never attained full size or strength. Spasticity was moderate, and even this seemed less after about 10 years.

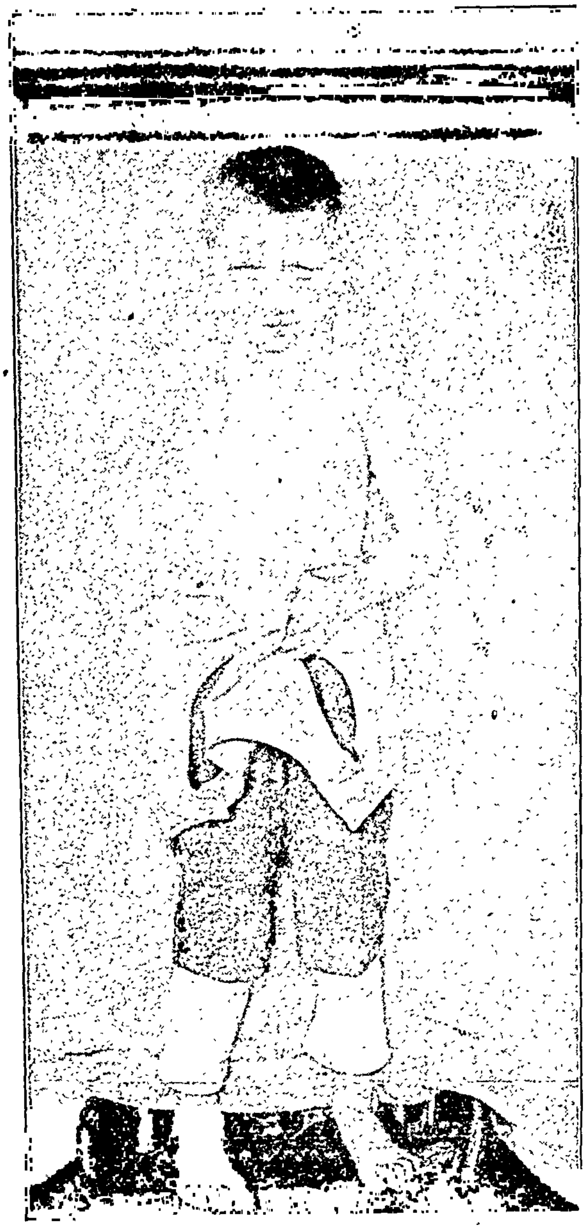

Fig. 7.—Case 9.

CASE 15.—Annie D., aged 3 years 8 months. Second in family of four children. The eldest this last winter had an attack of meningitis, which was followed at varying intervals by epileptic seizures. The labor was normal. At 4 months of age patient had pneumonia, from which attack she did not recover for two months. At the same time she had a suppurative otitis media. During that time it was noticed that the right side was not used as freely as the left. At present she is well developed and nourished. The affected side is a little smaller than the opposite. The head is normal in size; strabismus, right hemiplegia, contracture and rigidity; slow about learning to talk, did not attempt to talk until 3 years of age, and speech is still very limited, with articulation indistinct. She understands all that is said to her, and shows no deficiency in mentality. Reflexes are exaggerated. Has never had any convulsions.

CASE 16.—Celia C., aged 9 years. Second child in a family of six, all the others living and well. Parents in good health. She was well until October, 1899, when she had a suppurative cervical adenitis. This opened spontaneously, and nothing further was noticed until early in March, 1900. On coming home from school one day she complained of pain in left side of the chest, and headache. She was restless during the night, and in the morning began having general convulsions, and became unconscious and cyanosed. With only short intervals of partial relaxation she continued in convulsions for nine days. Since then there have been no recurrences, but following these there was left hemiplegia. The pupils react to light; the hand is nearly a typical claw hand. She is very irritable and noncommunicative, rarely asking or answering questions unless so inclined. She hears and understands quickly.

CASE 17.—Eva T., aged 4 years. Family history negative. She had never had any illness; had never walked, and had not even been able to stand; strabismus since six months old; had never had convulsions. The head measured 21 inches; the face large and expressionless; reflexes exaggerated; spasticity of legs which were held stiffly extended; intelligence almost *nil; made a few sounds which her mother could interpret.*

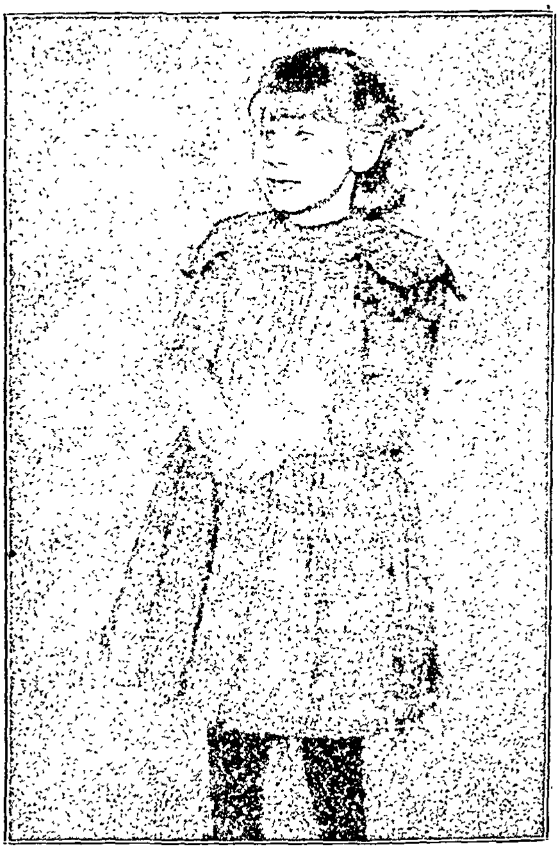

Fig. 8.—Case 11.

CASE 18.—Giovanni H., aged 6 years. History incomplete, as his mother understood and spoke but very little English. His father was described as not strong enough to work, "no good." There were five other children, all living. An older sister, a girl of 14 years, had had several attacks of chorea, and another sister showed some mental deficiency. The head measured 19 inches; the ears stood far out from the head; Darwinian tubercles present; eyes wide apart; saddle-shaped jaw; lanugo all over body. Musculature was good, but patient could not walk any better than a child 1 year old; his mental development also was backward, not being able to talk better than a child of 1½ years; never had convulsions.

The acompanying tabulated outline shows the common clinical features:

Fig. 9.—Case 12.

Fig. 10.—Case 13.

Sex.— Of this collection 18 are females and 7 males. The majority of the writers on this subject have stated that more boys are affected. Osler reported that he found no difference in the sexes and Gowers' cases showed more girls than boys.

Time of Onset.—The table shows that the probable commencement of the disease dates from or before birth in 17, while in 5 of the remainder the symptoms developed during the first year. This agrees with the findings of others, who report that the large majority occur under one year. It would seem to corroborate the opinion that the "younger the infant the greater the damage done; the more immature the brain, the more is its development likely to be interfered with." Nevertheless, Collier holds that the tissues of the young have more inherent vitality for repair than do those of later life.

Exciting Causes.—An analysis of the exciting causes from the clinical histories gives: Accidents of birth 7, or 28 per cent.; accidents, infections or autointoxication during infancy or childhood 7, or 28 per cent.

Form.—The high percentage of diplegics in this table —7 out of 25, 28 per cent.—attracts our attention. In the large number of cases collected by Sachs and Peterson the diplegics form only 15 per cent.

Fig. 11.—Case 14.

Convulsions.—Eighteen, or 72 per cent., gave history of convulsions during some part of the disease. In fact, it is most frequently for this symptom that the child is brought to the clinic.

Mental Conditions.—As to mentality, it is seen that out of 11 double-sided lesions 7 are idiots, two others are mentally impaired, while 1 only is nearly normal. Out of the 8 hemiplegics only 2 are idiots, 5 more or less impaired. and 1 nearly normal, which shows the preponderance of damage from lesions affecting both sides of the brain.

Size of Head.—That over half are microcephalic, merely emphasizes the well-known fact that there is an arrest of brain growth in these cases. In fact, the same arrest may occur in the hydrocephalic. It is nothing more than fair to call attention to the fact that some of these cases are seen so early after the onset that added time would doubtless show a still larger number of disproportionately small heads.

Irregular Movements.—The small number of patients (2) exhibiting athetoid movements will attract attention, and these two were both found in diplegics, as seen in the illustrations (Nos. 4 and 5). This is contrary to general observation.

Dysphasias.—As might be expected, dysphasia, more or less marked, seems to be the rule. It is interesting to note that the cases showing improvement in speech, after complete arrest, were hemiplegic. This is suggestive of the utilization of the unaffected side of the cerebrum, which comes to the relief of aphasia caused by lesions occurring in early life. Of the 7 cases of diplegia, 4 show permanent dysphasia, 1 can say but a few monosyllables, 1 is slow of speech and 1 has difficult speech from paresis of muscles required in vocalization.

In this last case, Mattie K., it may be mentioned that the mentality shows but slight, if any, permanent impairment. This is proved by the fact that she learned readily the fortnight she was sent to school and that she is bright and useful around the house. The interesting feature of this case is the escape from mental impairment in a case of diplegia, although presenting nearly all of the typical symptoms, viz., spasticity, contractures, convulsions, microcephalia, strabismus, ptosis, exaggerated reflexes with athetosis, choreiform and associated movements.

Fig. 12.—Case 16.

In the case of B. L., with history of long labor and forceps delivery, followed by eclampsia for five days; child asphyxiated for three hours; right hemiplegia, spasticity, contractures, exaggerated reflexes and some mental impairment, we have a marked intention tremor, which, with his slow, monotonous speech, is suggestive of multiple sclerosis of the cord; but it lacks the nystagmus commonly associated with these lesions. Spencer found, out of 130 autopsies, 4 on stillborn infants, 30 with hemorrhage into the spinal cord and canal. With this in mind, may it not be fair to presume that this child suffered from spinal as well as a cerebral hemorrhage?

Case 21.—Mamie Q. is 10 years of age, with slight mental impairment, choreiform movements, convulsions, and a history of meningitis at one year. Although presenting no spasticity, contractures, paralysis, exaggerated reflexes or difficulties of speech, I have classed this as a case of cerebral palsy. Sachs says: "The choreiform movements occurring after cerebral palsies deserve some special notice, for such conditions are at times mistaken for cases of ordinary chorea.

Case 22.—Male, aged 5 years, 6 months, a microcephalic idiot, with marked lalopathy and history of convulsions, is also wanting in the usual distinguishing symptoms, as are Cases 23, 24 and 25. These four cases, I believe, are properly rated as cerebral palsies under the broader classification given at the beginning of this paper. As long as we use the term "cerebral palsy," should we not include thereunder all conditions in which the principal etiologic factor is evidently a brain lesion, affecting the motor, speech or intellectual areas, whether due to thrombosis, embolism, hemorrhage or meningitis, resulting in sclerosis, effusion, growth or porencephaly?

Fig. 13.—Case 17.

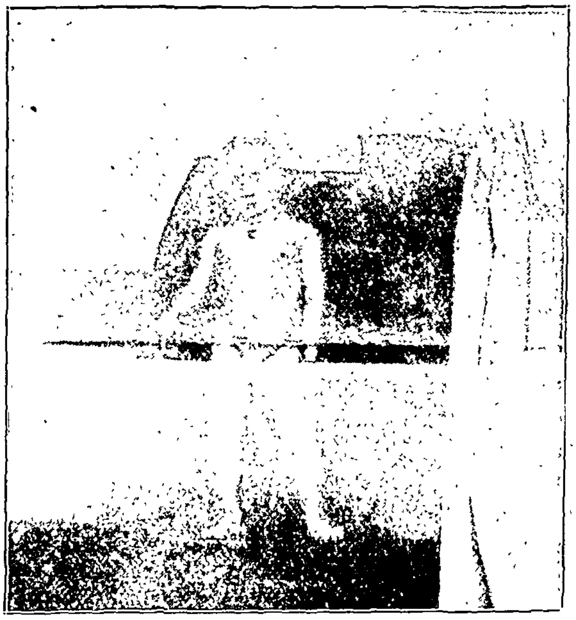

Fig. 14.—Case 18.

DISCUSSION.

Dr. William M. Leszynsky, New York—Regarding idiocy and imbecility, I think they may often be classed in the same category as the infantile cerebral palsies, for the latter are frequently associated with mental enfeeblement. I was surprised to hear Dr. Wilmarth say that better individual train-

ing could be brought about in institutions than at home. There are certain exceptions to this rule; for, under proper surroundings, individual management, I think, can be carried out better at home, or in a very small institution in which only four or five children are taken. As to the circulatory disturbances, I do not think that Dr. Taylor has proved his point. It seems to me that they are more probably the result of a cerebral defect reacting through the vascular centers in the brain. Much more can be said about infantile cerebral palsy. I think it would be an excellent rule for the general practitioner to examine every child brought to him suffering from epilepsy for evidence of infantile cerebral palsy. These children may make a certain amount of recovery, and the condition of partial paralysis may not be manifested sufficiently to attract the patient's attention, until symptoms of epilepsy are developed, either in the form of petit mal or grand mal. The most unsatisfactory epileptics to treat are those in whom the epilepsy is a terminal condition of the cerebral palsy.

Dr. J. P. Crozer Griffith, Philadelphia—The mistake is very commonly made of calling many cases chorea, Friedreich's ataxia, etc., which are really due to cerebral injuries in early life.

I wish to call attention to the rarity of tremor as a post-cerebral symptom. I notice that Osler, in his book on cerebral palsies, reports, out of all his cases, only one of post-hemiplegic tremor. I have myself seen only one case. It is certainly a comparatively rare condition, whereas the spastic conditions—the cases of single or double choreiform movements—are undoubtedly very common indeed.

I can heartily indorse what Dr. Leszynsky has said about the relation of cerebral palsy to epilepsy.

Dr. J. Madison Taylor, Philadelphia—In reply to Dr. Leszynsky's criticism of Wilmarth's assertion that the best treatment for defective children is to be had in institutions for the management of imbeciles, I desire to say that at one time I entertained the same opinion, because there was reason to believe, from analogy, that home treatment should be the best. I wish to say now that experience has taught me differently, and I am convinced the best results can be had by systematized and specialized instruction among children of the defective classes, with others of similar grade alongside of them as stimulants to effort. It is easy to imagine that the opportunities afforded by limitless wealth might give an equal or better training at home, but I am sure that the average case can be better handled in institutions properly equipped for such instruction. The subject is most important, and one on which the physician is constantly consulted, and he needs to form clear concepts on the matter.

Dr. Cotton—We are all anxious to hear what those who are conducting an educational system for this unfortunate class have to report. With one exception, these twenty-five cases were taken from my clinical records of the past year. The exception is the case represented by photograph No. 14. The child had meningitis at 6 months. There were repeated convulsions, and a semi-comatose condition supervened, which lasted four days. At 12 years of age the child was sent to the School for Feeble-Minded in Illinois. He improved there so that he could play in a band and could use certain tools. The outlook for that case was at first gloomy, but the results have been such that I believe the importance of educational work can not be overestimated.

THE MILK-CONTROL IN THE KAISER UND KAISERIN FRIEDRICH HOSPITAL IN BERLIN.*

DR. SOMMERFELD.

ASSISTANT CHEMIST AT THE HOSPITAL.

BERLIN.

In this report I shall deal with the determination of temperature, the specific weight, the chemical analysis of foreign matter and the bacteriologic examination.

---

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

When the milk is brought into the hospital, the dairymaid takes the temperature of the milk, and makes a record of it, which is filed in the journal of the laboratory at the end of each month. The temperature shows whether the milk has been properly cooled. It should not have a higher temperature than 10 C. If it should be higher the sender is notified, who must remedy this, and if it occurs again he is subjected to a fine. The specific weight is obtained by means of an exact areometer. If there is any doubt we first take the specific gravity of full milk, allow the cream to rise in a cylinder, remove the skimmed milk by means of a faucet near the bottom of the cylinder and again take the specific gravity. After a great many examinations, we find that full milk from our stable has a specific gravity of 1029 to 1032; and skimmed milk of 1032 to 1038. By testing the acidity of the milk we frequently can determine its freshness in suspicious milk delivered. The acidity is determined by a sample taken from a can, a second sample being put into a thermostat and allowed to remain there for one hour at a temperature of 37 C. If there is any difference between the two, the milk is at once questioned, and regarded as not being fresh. To determine this, 25 c.c. of milk are mixed with eight to ten times as much distilled water, to which 1 c.c. of a 2 per cent. alcoholic phenolphthalein solution has been added. To this is added a solution of barium hydrate, 10.69 gm. of baryta to a liter of water. This is filtered until it leaves a faintly red color. To secure this with our infants' milk we need from 15.8 to 17.5 c.c. of barium solution, whereas with the ordinary milk we need from 16 to 19 c.c.

Exact chemical and also bacteriologic examinations are made at different times, or when specially called for. Through sudden and unexpected taking of samples we obtain valuable analytical data. Such analyses are made for the determination of dry substances, fats, albumin, sugar, mineral salts, acidity and specific gravity. Dry substances and fats are determined at least once a week. The first is accomplished by subjecting 10 c.c. to a temperature of 110 C. for twenty-four hours in a platinum vessel. Fats are determined by the Soxhlet's areometric method, or after the Libermann-Szekely-Weiss method: In a small glass-stoppered cylinder 50 c.c. of milk are placed, to which 5 c.c. of caustic potash, 50 c.c. of petroleum ether—low boiling—and 50 c.c. of alcohol (96 per cent.) are added and shaken three times, for five minutes each time. The whole layer of fat is contained in the petroleum-ether, from which all liquid parts can be removed with the pipette and evaporated to dryness. The dried residue which remains after being subjected to a temperature of 105 C. is weighed and the comparative amount estimated. Our infants' milk during the last three years has contained 3.26 per cent. of fat.

To determine the amount of milk impurities we examine several times each week. This is done after the method of Renck-Stutzer, improved by Sommerfeld. This consists of a jar with a stopper, containing about 1½ liters, having an additional small bucket on its side which ends in a faucet. All sharp corners serve as dirt-receivers, and have been avoided, therefore the apparatus is rounded from top to bottom. This is filled with a known quantity of milk, and is kept standing for about two hours. By this time the foreign matter has settled and sedimented in the small compartments. The clear milk is now drawn off by the faucets on the sides. The attached utensil is taken off and the milk, combined with the dirt, put into a goblet, diluted with water, and then put into a filter, which has previously been weighed. This is washed over and over again with distilled water until the filtered portion is perfectly clean, then washed once with alcohol, and once with ether, and lastly dried at a temperature of 110 C. Thanks to the thorough cleanliness, the milk for nurslings seldom contains doubtful masses of dirt. As the cream rises in the apparatus while standing, we utilize the same opportunity for determining the specific gravity of the skimmed milk, since this runs off first on opening the faucet.

The bacteriologic examination of the milk is made with a view to determine the character of the bacteria present. The determination of the various forms is made in special instances, e. g., with the milk of newly-acquired cows, and when any special cow is suspected. A great many bacilli and cocci are utilized for cultures and animal experiments, to see how they affect sterile milk and to prove their harmlessness. As the cows are under the supervision of physicians, and as the milk is never used in the raw state, we have seldom occasion to examine the milk for pathogenic micro-organisms, since it is a known fact that pathologic bacteria are destroyed at 100 C. Nevertheless, we convince ourselves that none is present, especially the tubercle bacillus, by injecting guinea-pigs at monthly intervals with milk sediment procured by centrifuging. Up to the present we have found none that are pathogenic. To count the number of germs it is necessary to dilute 0.1 c.c. of milk with sterile water, the milk being taken from the cans in a sterilized pipette, and, depending on the time of the year, to inoculate either nutrient gelatin or nutrient agar therewith.

The counting is done by means of Petri dishes, which are used in making the cultures, the under side divided into squares. The gelatin plates are put into a temperature of 22 C., and are counted after twenty-four to forty-eight hours, whereas the agar plates at the same temperature are counted after twenty-four hours. Samples of the milk are taken from the sterilizer and put into the thermostat at a temperature of 37 C., to prove how long the milk will keep. Milk specimens which do not curdle during the first twenty-four hours shows that the lactic acid bacilli are killed. As the milk is used within ten hours after the sterilization, in the wards, of the hospital, we take samples of milk from the ice after eight hours. The negative results of our examination prove that the sterilization has been satisfactorily performed, although we frequently see, on the other hand, that the milk could hardly be classed as germless.

THE MILK-SUPPLY IN THE KAISER UND KAISERIN FRIEDRICH HOSPITAL IN BERLIN.*

PROF. DR. A. BAGINSKY.
DIRECTOR OF THE HOSPITAL.
BERLIN.

The attention given by American physicians to milk-supply and milk-sterilization for nurslings prompts me to give my experience in this regard, for I believe that in our hospital we have reached the highest point attainable on this subject. Depending on our milk-supply from neighboring stables, and having noticed the inadequacy of this supply, we made it a point to acquire such a stable for the hospital, especially since we, through an arrangement with the municipal authorities, were called upon to treat a large number of sick nurslings in which the strictest possible care of both the production and the milk-supply could be maintained and carried out. Owing to the success attained in this regard we have not found it necessary to establish our own dairy. By means of contracts we are able to control several special milk-dealers who are compelled to carry out the rules given them, and they have learned that only the most exact attention to detail will prevent our criticism. In order, therefore, to produce the best possible product of a dairy, it has been necessary for me to watch every detail, and in this I have been most ably supported by my assistant, Dr. Sommerfeld.

---

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The control of the milk-supply necessarily begins with the stable, which is divided into two floors, and is built of Rathenower bricks, iron and cement. The lower floor is divided by a large massive wall into two parts, which have separate entrances, a larger and a smaller, the upper story representing one room. The dimensions of the buiding, which has large windows on both the longest sides are: length, 30 meters; breadth, 11 meters; height, 4 meters. The floors throughout are of massive stamped cement, and are sloped so that there is a thorough flow into the sewer. The walls are covered with glazed brick to the height of a man, over which is a coat of white paint. The cows stand on so-called food tables, which are placed at right angles to the longest side of the stable. These tables are made of cement, 2 meters wide and 8.50 meters long, in which mangers of glazed clay are placed. In the upper stable there are three such tables which are arranged for seven cows on either side, so that forty-two animals can be kept in the entire stable. The food tables are more practical than the mangers which run along the whole wall, because one can better oversee and observe each animal separately. The separate stands for the cows are raised and are 2.75 meters long, sloping with a heel in the back. In the standing and lying position the buttocks of the cows stick out over the stand so that the animals very seldom lie with the udder in the dung. The water-supply is furnished by means of an automatic working "self-drinker," which is attached to the water-works. The animals can in this way drink when they want to, the waste water being replaced by running fresh water.

The larger portion of the lower stable is arranged exactly like the upper portion. There are two feeding stands intended for procuring milk from 28 cows fed on dry fodder only, the smaller portion contains six stands for the observation of specified cows. This serves as a quarantine, and isolating stable for newly-acquired cows, and eventually for cows which show signs of sickness. In all the stables the cows stand on sawdust, which, on account of its cleanliness, is more approved than the dark black turf grass, the filth being more noticeable and calling for a better cleaning. The disinfecting element of the turf-grass is less advantageous than that of the sawdust. The stables are cleaned by washing and flooding the floors and the tiled walls; also by frequently whitewashing the walls. The manure is pushed through convenient openings directly into brick pits built in the yard adjoining the walls.

The dairy is entirely separated from the stables, and is in a special building. This is very light, and is on a level with the cellar, where an evenly cool temperature is obtained. It is finished throughout—the floors, walls and ceiling—with flat white bricks, has well-water supplied by the water-works of Berlin and a cooling apparatus. Here the fresh-drawn milk from the stable is filtered, cooled and put into the cans ready for transportation. Utensils and cans in which the residue of milk remains can not be brought into this space. In the same manner we prohibit the entrance of dairymen, drivers and others not employed in this department. All soiled utensils are placed in a special wash-room adjoining the dairy, entirely separated from this room by means of a wall, and having a distinct entrance.

The cows belong to the Holland breed, and are under constant veterinary supervision. All animals are injected with tuberculin and only those animals totally free from tuberculosis are put to use. The injection of tuberculin is repeated several times. If the weather permits, the animals are given several hours of outdoor exercise, which has proved of great advantage.

The feeding is done in two ways. The animals whose milk is to be used for infants are given dry fodder. Swill is entirely forbidden for those receiving moist fodder. It has been frequently noticed that from the residue made by the distillation of brandy from potatoes and corn, animals have a tendency to diarrhea, and their milk has a tendency to produce toxic conditions, the nature of which can not be proved by either bacteriologic or chemical examinations. The dry-fed cows get the best of clover, certain residues from a brewery, wheat, bran and rye, and to stimulate the appetite, small quantities of dry cut molasses. The cows receiving moist fodder are given turnips, rye-bran, wheat-bran and hay. The proportional quantities of the amount of the entire feeding are the following:

Dry fodder: To 500 kilo., live weight, 12.5 kilo. clover, 2.5 kilo. rye-bran, 2.5 kilo. wheat-bran, 1.5 kilo dry treber.

Moist fodder: To 500 kilo., live weight, 22.5 kilo. moist fodder, 20 kilo. turnips, 0.75 kilo. rye-bran, 0.75 kilo. wheat-bran, 4 kilo. hay.

From this feeding we receive 8 liters of milk per day with dry fodder and 10 to 11 liters with moist fodder. The animals are milked three times a day, at 3.30 a.m., and 12.30 and 4.30 p.m.

Before milking, the damp stable is cleaned. The dirt is swept together after the dampness has disappeared, and the passageways are flooded with water. Immediately before beginning work, the dairymen are compelled to thoroughly cleanse themselves, and especially wash and scrub their hands with soap and water, and then to carefuly cleanse the udder of each animal with soap and warm water, and a clean cloth. On thorough cleansing of the udder great stress is laid, because therein lies the greatest chance of infecting the milk from the dirt of the stable, hair, etc. We believe that by using the above-mentioned precautions, we can safely dispense with milking machines.

The freshly drawn milk must be immediately taken from the stable and brought to the dairy. When there are a large number of cows, the milk taken from the first must not remain until all are milked. The reasons for this immediate removal of milk are the danger of contamination with bacteria, which are found in the air of the stable and are mostly of the hay and potato variety and are very hard to destroy, and the fact that warm milk easily absorbs odors, such as perspiration from the cow, so that it tastes like a "cow stable." The milk is immediately filtered and cooled in the dairy. The filtration is done through linen cloths, which are boiled each time after being used; the cooling is done by the aid of a cooling apparatus. By this careful method of collecting the milk, its filtration through boiled and clean linen cloths has proved sufficient. This is simple and inexpensive method. Filtering ap if the filter is not carefully cleaned—by steam—are very good harbors for dirt and bacilli. The filtering cloths, on the contrary, easily can be kept clean and sterile by thorough boiling. The cooling machine is a square zinc-plate box, whose broad front, back and sides are made of tin. Through openings made in the narrow side-walls a stream of cold water flows down on the inside and flows out again through openings in the opposite side. The milk flows through a cooled interior, and has its outflow in a receptacle placed below. The spaces between the separate indentations are very small, so that the milk can not flow off too rapidly, as part of it is retained through its capillarity. In this way the slowly-flowing milk is cooled by passing over a large area. The cool water flows from a deep well and may be cooled still further by passing through an ice-box. The cooled milk at the time of the delivery has a temperature of 10 C. The transportation utensils —milk cans—in which the milk is transmitted to the hospital, are made of galvanized tin, and can be opened to ensure thorough cleaning. If the cans can not be cleaned immediately after the milk has been emptied they are filled with water, as dried milk residues are very hard to remove and might be overlooked. Milk is obtained three times daily, and sent three times to the hospital. It is strictly forbidden to deliver milk which has stood some time. (See article on "Milk Control.")

In the hospital the milk is received bv a maid especially employed for this purpose, who has no other duties but the storing and sterilizing of milk and attending to all duties pertaining thereto. She is especially instructed regarding her duties, and the fact is made clear to her that the life and health of the children depend on the careful and strict fulfilment of her duties. She must therefore see that her body is kept absolutely clean. Her uniform consists of a wash dress and a large white apron, covering the entire body. Before beginning her work she must cleanse her hands with a brush, soap and lukewarm water. The dairymaid inspects the cans as to their cleanliness on receiving them and tests the temperature of the milk. Irregularities, such as the non-delivery at the stated times, poor measure, improper cleaning of cans, wrong temperature of the milk, etc., must be immediately reported to the chemist of the institution, who has this under his control. The delivered milk is utilized at once. The milk for the use of the house and the older children is cooked in copper vessels, then put into clean receptacles and into the icebox, because it is not immediately sent to the hospital. The milk for infants, which is either full milk or a milk mixture, with hot-water or oatmeal gruel, according to the prescription of the physician, is put into bottles and sterilized.

The greatest stress is laid on the absolute cleanliness of the bottles. These are put into hot soda-water, washed with a bent-handled brush, and cleansed of any particles of milk which may have adhered; they are then placed in a specially constructed rinsing machine connected with flowing water, and rinsed with coarse sand, then with clear flowing water, and finally washed again with sterile water. The empty bottles from the infectious wards are first put through a disinfecting process in a large disinfector of the hospital, and are kept in steam for thirty-five minutes at a temperature of 104 C. The bottles are graduated in cubic centimeters and are made after my own model, in sizes of 300, 200 and 100 c.c. After the bottles are filled, a plug of cotton is inserted in each, and after being sterilized in like manner, are sent to the different wards. As the milk is carried in baskets, it is unnecessary to have any other stoppers.

The sterilizing is done after the Soxhlet method in a Henneberg milk-sterilizer, which holds 264 bottles; for extra use there is a reserve apparatus after the Autoclave method, consisting of a large copper cylinder, having steam connection, in which two frames, each containing 32 bottles can be placed. The cylinder can then be made air-tight. The Henneberg sterilizer consists of a forged iron cabinet resting on legs, which has an air-tight door in front. On the inside of the cabinet there are movable grates, as a protection for the bottle-holders. The steam flows into this cabinet by means of a very fine pipe through the bottom, surrounds the milk bottles and replaces the specifically heavy air which is carried out by means of a second pipe in the bottom, into a chimney and out into the open air. The machine is, furthermore, supplied with an air valve for quickly removing the steam after the sterilizing is finished; a safety pipe to prevent too great pressure, and also with a thermometer. The temperature can be raised to 105 C. We sterilize at 100-101 C., and after the temperature reaches 100 C. the milk remains in the sterilizer thirty minutes.

The criticisms which have recently been made against the strict sterilization of milk I can not approve. I have never seen any harm arising from the use of fresh sterilized milk, and I believe that those authors who declare that sterilized milk causes Barlow's disease, really mean that the prolonged use of sterilized milk, procured from public milk-sterilizing laboratories, which frequently have a large stock of sterilized milk remaining on hand for possibly several months before being used, has unquestionably produced Barlow's disease. Even if it be admitted that the sterilization of milk for the feeding of children is combined with disadvantages, one can hardly use any other than sterilized milk in a children's hospital. In young children, with a tendency to intestinal disease, the danger of infection by means of bacteria existing in the milk is very great. We have every reason to be satisfied thus far with the sterilization used in our hospital.

Regarding the dilution of milk and its use in the varying dilutions, I can hardly see how we can do without this for sick children, notwithstanding the fact that French physicians have recently advocated the use of full milk. I am convinced that pure milk does not agree with dyspeptic children in the hospital, and as often as I have tried this, even with small, measured quantities of pure milk to nourish severe cases of dyspepsia, I have been forced to stop on account of the reappearance of vomiting and increase of diarrhea. I therefore can not dispense with the diluting of the milk. Numerous additional substances used in the diluting, such as water, gruel, rice-gruel, barley-gruel, etc., I hold to be absolutely necessary in diarrheal diseases. I see no reason for doing away with our present methods.

Suture in Tiers Without Buried Threads.—The silk thread or silver wire is passed through the deepest tier of tissues for one stitch. The ends are then drawn and held tight with forceps. A piece of No. 3 catgut is then passed around the thread below the forceps and tied in three tight knots. The upper tiers are then sutured together in the same manner, with the ends of the thread emerging from the deep tier and tied around the catgut close to each tier of tissues. Each stitch is thus directly above the one beneath. This method was exhibited by Hagopoff at the International Medical Congress for the first time.

THE RELATIVE VALUE OF HOMATROPIN AS A CYCLOPLEGIC: A CLINICAL STUDY.*

E. C. ELLETT, M.D.
Ophthalmic and Aural Surgeon to St. Joseph's Hospital, City Hospital, Lucy Brinkley Hospital, Children's Home, Shelby County Poor and Insane Asylum and Leath Orphan Asylum.
MEMPHIS, TENN.

The question of the value of homatropin as a cycloplegic was brought before the Section last year by Dr. Culver; nevertheless I believe we can profitably discuss it again. On account of the short time required for the effect of homatropin to pass off, it is a cycloplegic much to be desired provided it is effective, and this is a matter in regard to which opinions vary. I am a firm believer in the necessity of using a cycloplegic for measuring the refraction if we desire to do work which will be lasting in its effects and which will reflect credit upon us in its results, though I am aware that there are many men whose opinions carry much weight who seem content with the results obtained by estimating and correcting the dynamic refraction. I take it, however, that we can dispense with any arguments as to why we are interested in the subject of cycloplegics and why we habitually use them. Suffice it to say that most of us are satisfied from clinical experience that they are not only justified, but demanded, and that we do use them for two purposes: 1. To obtain complete rest for the eyes, and thus relieve choroidal congestion and low-grade inflammatory processes in the deep tissues of the eye. 2. For the purpose of accurately measuring the errors of refraction. While we may not agree as to the theoretical indications for the use of a cycloplegic, I believe that when practically confronted by a patient, the majority of us would be of one mind as to whether or not to use such a drug in that particular individual.

Atropin, the best cycloplegic we possess, in the vast majority of cases produces complete cycloplegia, which lasts sufficiently long to give the eye a thorough rest and permits of several examinations on different days. With homatropin, the most fleeting of cycloplegics in its effects, we are usually compelled to be content with one examination, and, as ordinarily used, the rest it affords is so short as to have little or no therapeutic virtue. Various drugs stand between these, viz., scopolamin, hyoscyamin and duboisin, the last two at least being chemical accidents, and may be looked upon as modified atropin. The question with which this paper has to do is: Does homatropin produce a sufficient effect on the ciliary muscle to be a reliable agent, and if so, in what manner and in what dose is it best to use it?

The fact that so many persons can not afford the time necessary for the use of atropin compels the use of a more quickly acting drug. I began using homatropin hydrobromate in solution and tried it in the strength of 8 and 16 grains to the ounce, instilling one drop every five or ten minutes for an hour. I finally settled on a solution of 12 grains to the ounce as giving, as I thought, satisfactory cycloplegia with a minimum of risk of constitutional effects. This solution is irritating, producing conjunctival and ciliary injection, to avoid which I preceded it by a drop of 4 per cent. cocain solution. I used this solution when I could not use atropin, with tolerable satisfaction for about four years, and then I began the use of the discs of homatropin and cocain, prepared after the formula of our colleague, Dr. Casey Wood. Each disc contains 1/50 of a grain each of homatropin and cocain (alkaloids). My method of use is the same as that proposed by Dr. Wood, and is as follows: First, a drop of cocain solution is instilled for its anesthetic effects, as the use of the disc is somewhat painful. Then the patient is directed to look down, and the disc, carried on the end of a cotton-tipped applicator, is placed on the conjunctiva above the cornea, and the eye closed before any winking can occur, which might expel the disc, and the handkerchief is placed over the eye. In the same way, a disc is placed in the other eye and the patient keeps both eyes closed. A second and then a third disc is introduced into each eye at the end of thirty and sixty minutes, respectively, and thirty minutes after the last one is applied the patient is ready for the test. In testing the refraction my reliance is placed chiefly on the test lenses and the shadow test. Many eyes thus treated will be found to present, at the end of ninety minutes, considerable irritation, with both conjunctival and deep ciliary injection. This may be relieved by instilling another drop of cocain solution.

Comparative studies have been made to ascertain the relative efficiency of the different cycloplegics, especially comparing homatropin and atropin. I might refer to those of Wood, Coleman, Starky, Jackson, Oliver and Risley, as indicating that while in many, nay most, cases the efficiency of homatropin has been proved, in a respectable number atropin reveals the more hyperopia, and sometimes more astigmatism and sometimes a change in the axis of the astigmatism.

It may not be amiss to refer to the reasons which Dr. Wood has advanced for using the drug in connection with cocain, in a gelatin disc and in this dose. He believes[1] when homatropin in aqueous solution is dropped into the eye, 90 per cent. of it escapes by the tear passages or over the cheek. When applied in ordinary solution, they dim the cornea while the gelatin is completely absorbed and yields the drug slowly. The addition of cocain increases the absorptive power of the corneal epithelium, and the disc of most useful size will contain only 1/25 of a grain of an alkaloid. Further, the method of keeping the eye closed is a protection to the corneal epithelium from the deleterious effect of cocain. This disturbance of the epithelium is urged as an argument against the use of the combination, by Thorington,[2] but I have searched carefully with oblique illumination and the loupe, and have failed to detect its presence. I would further suggest that closing the eyes prevents expulsion of the disc from the conjunctival sac, and intensifies the cycloplegic action of the drug by removing incentives to the exercise of the accommodation, and by excluding the light.

Aside from the vulnerability of the particular ciliary muscle, the question of the efficacy of homatropin seems to me to depend largely on the methods of its use and the dose. The discs as indicated, furnish a means of applying the homatropin almost continually for ninety minutes. Jackson[3] says that we can not rely on single or hourly instillations—referring to solutions—but must use them at intervals of a few minutes. He uses a solution of 12 grains to the ounce. With many of those who have gone on record as finding homatropin unsatisfactory, we can see the reason in their method of its use. This is certainly true in the case of Holt,[4] who used a 3 per cent. solution nine times in sixteen hours, and hourly for four hours before the examination. Coleman,[3] however, was dissatisfied with the results, after using all sorts of solutions and discs. In looking over Coleman's table, the difference, where difference exists, is in most cases slight compared to the total error, and can not be laid wholly to the door of ineffectual cycloplegia until the personal equation of both tester and tested can be eliminated.

[2] Refraction and How to Refract.

[3] Trans. American Oph. Soc., 1889.

[4] Ibid.

I will present here in tabular form the results in some cases which I have had the opportunity of examining, first under homatropin, and later under atropin. These observations are clinical, not experimental, and represent cases in which the correction prescribed under homatropin was for some reason unsatisfactory. They are not selected cases, and are, moreover, made on eyes suffering from eye-strain. It would appear that such observations have value, for we use cycloplegics on such eyes in more instances than we do in eyes not so affected, and the object of the study should be to determine the relative value of the cycloplegics on pathologic eyes. The only fact that detracts from the value of the table is that the second examination was made several months after the first, and it is possible that in a few instances a real change in the static refraction may have occurred. The results are those obtained by the test lenses, all the cases being private patients and all tested as carefully as I know how.

* Obstinate case, prolonged atropin.

† One year between tests.

In 52 observations the following results are noticed: Gains for atropin were .25 D. 14 times; .50 D. 14 times; .75 D. 3 times; 1.00 D. 3 times; 2.00 D. 2 times; total 36; average gain .54; results identical 12 times. Homatropin gains were .50 D. 3 times; .25 D. 1 time; average gain for homatropin .44. Average gain for atropin in 52 observations (meridians) .385.

In two of the cases showing a gain for atropin of 1 D., and in the two cases showing a gain of 2 D. the first examination was made with homatropin in solution, the second with atropin about three or four years later. It is hardly fair to compare the two drugs in this way. In addition to these differences, I have noted the following changes in the cylinder[6] axis; 5° once, 15° three times, 30° once, 60° once.

The results shown in the table are not what I thought they would be. Homatropin has been most effective in aiding in the selection of glasses, which have proved satisfactory after glasses prescribed without cycloplegia both by myself and by others have failed to do so. If the four observations to which I alluded be eliminated, we find a variation so slight that it will hardly affect the clinical result. I have noticed that in many cases tested with homatropin the shadow-test will indicate a glass .25 or .50 D. stronger than that which gives the best vision. As regards the cylinder axis I am not prepared to say that this is altogether due to more efficient cycloplegia, as the tests in most of these cases was made on individuals and under circumstances which made accuracy difficult to obtain.

The principal practical objection which I have to homatropin and cocain discs is the pain they cause, this being especially objectionable in children. I have demonstrated to my satisfaction in the same patient the superiority of discs to the solutions, and am not disposed to return to the use of the latter.

I may summarize as follows the conclusions which seem justified:

1. The necessity of cycloplegia in order to *accurately* test the refraction of young people is established, though *satisfactory* fitting can doubtless often be done without it. (Note the distinction between accurate and satisfactory.)
2. Atropin is, all things considered, the most reliable cycloplegic, but a great objection to its use is the length of time consumed.
3. For testing the average case, without much chorioretinal irritation or marked ciliary spasm, homatropin, properly used, is sufficient.
4. The best method is that of the homatropin and cocain discs, made after the formula and used after the method of Dr. Casey Wood.
5. In many cases atropin must be used, to relieve spasm, to procure rest and thus to allay chorioretinal irritation. In these cases the patient can no more justly object to its use than he can to its being used in iritis. In both cases his time and his business interests are secondary to the ultimate attainment of useful vision.

DISCUSSION.

Dr. C. M. Culver, Albany—Ever since studying with Dr. Nettleship, in Moorfield Hospital in 1881, I have considered that what has been said may be taken for granted, that the most complete cycloplegia is obtained by the long-continued use of atropin sulphate; but we must meet conditions that so often present themselves in practice where patients come without any premonition of long-continued treatment and expecting an optical prescription in a relatively short time. In using the atropin sulphate for determining refractive errors, I use it exactly as I do homatropin, that is, by the instillation of a few drops at intervals of five minutes until six instillations have been made, and then waiting until an hour, from the time of the first instillation, has elapsed. The comparisons that I have made show that in no practical way is the atropin sulphate superior. It still seems as if, in actual practice, a 1 to 40 solution of homatropin is that most useful. The transient action is desirable from one view-point and undesirable from another. While for a long time I used the disks, which seemed quite useful, there seemed to result from this use a roughening of the corneal epithelium that detracted from the accuracy of the optical examination and, contrary to the experience of Dr. Ellett, I came back to the solution which, comparatively, seemed to me to be the more effective.

Dr. Casey A. Wood, Chicago—After the discussion of this subject, both this and last year, I am sure I would be taking up your time unnecessarily if I were to repeat what I said on former occasions; but, if you will permit me, I wish to say that I still use the preparations for which I am responsible, and still believe that where we are unable to use atropin some such combination as I have recommended is desirable. It is, however, like a sharp instrument—good when properly employed, and harmful when not properly used. It must be in-

---

[5] Annal Oph. and Otol. January, 1893.

[6] The cylinder in each of these cases was a .25 D.

sisted on that when the disks are placed in the eye the latter must be closed, for if the eye be left open for any length of time the anterior epithelium of the cornea becomes dry and may interfere with the subsequent measurement of the refraction. When the lids are closed this loosening of the epithelium by the cocain allows of the rapid absorption of the homatropin, and is the agent that brings about cycloplegia.

Dr. Ellett referred to the use of the disks in children. I have lately discontinued their use for this purpose, chiefly because children's time is not, as a rule, of much importance, and I generally insist on the use of atropin, but when business men and women come to us and say, "I have a half-holiday on Saturday and must get to work on Monday," we have no choice. I believe it is better to use cocain and homatropin than to try to insist on the use of atropin, even though the latter drug may be thought preferable. In my experience I find it wise to tell the patient that if the disks are not satisfactory atropin or scopolamin *must* be used. There is an important fact to be borne in mind when making studies of the comparative value of cycloplegics. If one makes a second examination within a short time, no matter with what cycloplegic, there will often be found a difference in the refraction. I made a number of tests with this result some years ago, using atropin alone and waiting for ten days after the first to make the second examination. Not uncommonly, a greater amount of hypermetropia, or hypermetropic astigmatism, and a smaller amount of myopia, was discovered on the second trial, and the same was found in the case of homatropin and cocain. To arrive at proper conclusions, therefore, I am persuaded that at least a month must elapse between the two examinations.

DR. A. D. MCCONACHIE, Baltimore—While I endorse entirely all that has been said in favor of homatropin, I want to report some unfavorable experiences with it. I reported two cases in the *Philadelphia Medical Journal* a year and a half ago under the title "Two Cases of Homatropin Intoxication or Substitution, Which?" I thought the cases either idiosyncrasy or substitution. Further evidence by experiment and observation proved that the patients had not gotten homatropin. My usual prescription for homatropin is ½ gr. of the salt to ½ dram of distilled water, with directions to put 2 drops in each eye every ten minutes for six instillations; that means twenty-four drops of an 8-gr. to the ounce solution. After I had criticised the pharmacist, an investigation was taken up by our state pharmaceutical association, and I was arraigned for considering it substitution and dealing wrongfully with them. One of our ablest pharmaceutical chemists, however, examined the specimen, which, by the way, bore Merck's label, and found that it was not pure homatropin, but some salt allied to atropin. Merck, when consulted, said that it should only be used in .5 per cent. solution, and that I had used a solution strong enough to be poisonous—yet my solution is but half the strength recommended here. I was vindicated before the society by a pharmacist, however, and they admitted that there was substitution perhaps, not by the druggist, but by accident, and that some other drug had gotten into the bottle.

My object in referring to these cases is to impress the members of the profession of the dangers attending the use of homatropin of uncertain composition.

DR. F. C. HOTZ, Chicago—I think there can be no difference of opinion among us that homatropin, on account of its transient effect, is a valuable remedy. The question narrows itself down to whether homatropin is reliable in refraction work, because the majority of our patients who present themselves for refraction examinations have healthy eyes. I agree with the essayist in so far as I consider homatropin a reliable cycloplegic in the majority of cases. There are cases in which you may fail and have to resort to atropin. I have not made any comparative tests by using homatropin and following that in a few weeks by a second test under atropin, but I have had, in the course of a few years, a number of patients who returned for a second examination, and inasmuch as the first examination was made under homatropin, I decided then to examine them under atropin. I regret I have not had the time to go over my records to select a number of these cases, but as far as I can remember, many of the examinations showed the same results. In regard to the method of applying the remedy, I think to instill it every five minutes is a waste of homatropin. I use a drop of 2 per cent. cocain solution, and five minutes later a second 2 per cent. solution of homatropin. Fifteen minutes later a second application is made, and in 30 or 40 minutes after the first application I find the accommodation practically suspended and the eyes not irritated.

DR. J. L. THOMPSON, Indianapolis—I have had some experience with homatropin ever since it came out. At first I used the salt on the end of a probe, and afterward the disks. I always re-examine my patients whenever I can, about two years after the first test. In the great majority in which I used homatropin I find, under scopolamin or atropin, that I had not gotten out the full degree of the anomaly that existed, but occasionally you find a case where one or two applications of homatropin has been just as effective as atropin. Then, again, I have found that occasionally atropin does not bring out the full degree that exists. Duboisin I find the most reliable of all, and generally it makes the patient sick at the stomach. In about one-half of the cases in which I used homatropin I believe the full amount of correction was not brought out. Scopolamin has suited me a great deal better.

DR. WILLIAM THOMSON, Philadelphia—I think it would be better if each gentleman would explain to us the methods he uses to determine whether he has obtained a full degree of cycloplegia. My method of detecting it is to make an artificial far point by the use of a 3 D. lens, with small type for test.

DR. W. L. PYLE, Philadelphia—I do not think the argument that a subsequent examination under atropin will bring out more defect is valid, for I have often made examinations under homatropin and cocain after a lapse of eighteen months or two years from the tests under homatropin, and even atropin, and found quite as much increase in refractive error as these gentlemen report after using atropin following homatropin.

DR. S. D. RILEY, Philadelphia—I wish simply to urge the importance of using the mydriatics for their therapeutic value, even in correcting errors of refraction. Some one, in this discussion, made the remark that the majority of refraction cases coming to him presented healthy eyes. I must say this is not in accord with my own experience. A large number of my patients have fluffy choroids, headaches, etc. I feel sure that no rapid method will meet satisfactorily the requirements in these cases. The time limit is an important one, and if we use homatropin it should be for many days, until the hyperemia of the fundus has disappeared and the attending asthenopia symptoms have subsided. Until this is accomplished no certain correction can be made.

Neither subjective nor objective methods suffice to determine accurately the static refraction of such eyes when in a state of health. I prefer in these cases to use the more vigorous mydriatics, and the one I prefer above all others is the hyoscyamin sulphate, for it holds the accommodation in its grip more firmly than atropin and it subsides many days sooner—provided you get hyoscyamin. It is difficult to secure a trustworthy preparation, because in its manufacture too great heat or excess of alkali converts it into atropin. The only way to differentiate between them is by polarization. A chemist can not tell which is which in the laboratory, for they are isometric.

The strong mydriatics, if kept in a sufficient length of time, i. e., until the irritation subsides, permit the accurate and easy correction of any existing error of refraction to be made, but this can not, in my judgment, be done until that point is secured. I therefore insist upon the use of a mydriatic for its therapeutic value as well as its cycloplegic effects.

DR. E. C. ELLETT—In regard to Dr. McConachie's experience with poisoning by homatropin, I have noticed it twice in using solutions, but not at all in using the disks. These two patients were young ladies of the same age, and resembled each other strongly in appearance. About the irritation of homatropin, which Dr. Hotz thinks he avoids by preceding it with cocain, I have seen the same irritation produced by the disks, and relieved by cocain.

As regards determining when we have cyclop [illegible] I have used the same method Dr. Thomson [illegible] use a + 4 D. lens and then test with J. [illegible] to give a very short range of vision, and if there is any latitude at all I conclude that cycloplegia is not sufficient. I think where we wait for a year or more and then retest our cases an increase in the strength of the glasses may be indicated from the fact that the patient has worn glasses for that long, and that there has been a small amount of hypermetropia concealed by ciliary muscle tone or action that could not be overcome by the cycloplegic. I fully agree with what Dr. Risley has said with regard to the use of mydriatics in these cases of deep irritation. I said in the paper that one of the uses of these drugs is to procure rest, and mydriatics are as much indicated in certain cases of eye-strain as in iritis, and can not be replaced by any other substance.

SOME FACTS ABOUT APPENDICITIS. MEDICAL AND SURGICAL.*

J. H. CARSTENS, M.D.,
DETROIT, MICH.

Experienced surgeons make the statement that if they should have 100 consecutive cases of appendicitis and should operate on all of them as soon as the diagnosis was made, they could show a better list of perfect recoveries and a smaller death-rate than if 100 similar cases were treated on the expectant plan and those only operated on which were finally selected by conservative practitioners. I agree with the above statement, but not with the assertion of the ultra-conservative members of the profession when they say that the radical surgeons insist that every patient should be operated on immediately. I never heard a surgeon say so. Surgeons say that it would be better if every case could be operated on, but every careful surgeon selects the time and method of operation in each case. And each case varies. Even if we say that every case ought to be operated on, that does not mean that we recklessly rush in and operate without due consideration of the condition of the patient, the environment and the necessary treatment. We are called to consult in a case in which the patient has been ill for several days, and on our arrival at the house we find a decided change for the better has taken place. We see that the turning-point has been reached and that the patient is going to recover. Does any one operate under such circumstances? I know of none. We say that when the acute symptoms subside, and if the patient has had similar attacks before, we can operate in a few weeks. If, however, we see the patient during a first mild attack, then we suggest that the patient wait, since we know that about 15 per cent. never have a recurrence. But should there be another attack, we advise an operation. Many advocate waiting until firm adhesions have taken place. This has never seemed right to me. It can be justified only when one expects to get one of those very large, appendicular abscesses containing a pint or more of pus, with the sloughed-off appendix floating in it. Such cases simply require an opening of the abscess and drainage; but before one case reaches that stage fifty cases, at least, would end in death.

Furthermore, if the adhesions are firm—which is very good in "let-alone" cases, but a very troublesome condition when you have to break up the adhesions and remove the appendix—you are liable to strip up the peritoneal covering of the intestines.

Another idea which seems to me very objectionable, is that waiting in such cases is a good thing. "Wait until the power of resistance of the individual has been developed." When has it reached its acme? There is a limit to nature's power of resistance and I think this power as a rule is greatest in every case, when the disease has existed the shortest length of time. This brings us to a consideration of phagocytosis and leucocytosis—the power of resisting and eliminating microbe infection. As the infection becomes greater, nature offers more barriers to the onslaught, but a limit is reached in these cases also, and nobody can make me believe that a person who has been subject to a septic condition for five days is a better case for operation than one who has been subject to septic infection for two days, neither can any one make me believe that ten, fifteen or twenty days after the microbic infection, when all the reserve powers of the system have been exhausted, is a better time to operate on the patient than in the first twenty-four or forty-eight hours. It is so unreasonable, so opposed to all ordinary laws of health and to common sense that I have always rejected the idea.

There is a class of cases in which the surroundings are not conducive to aseptic surgery. We sometimes hear in medical societies, or even read in medical journals, of wonderful operations, performed in the little hovel or flat, where whole families were cooking, sleeping, eating and living in one room. We hear of these most wonderful recoveries under the most adverse circumstances, but we never hear of the thousands of deaths following operations under similar conditions. In those cases in which the environment and the after-care are bad, it seems to me that the surgeon ought to trust more to nature than to surgical skill, which will be nullified by the ignorance of the nurses in whose charge he leaves the patient.

Accurate statistics, furnished by surgeons, show one side of the question, but it is very difficult to get statistics of cases—recoveries and results—from general practitioners. It is almost impossible for the general practitioner to keep statistics if he wants to. When he attempts to write out his records, he is disturbed and must rush away, and so it goes on every day. He is tired out at night and can not sit down and write for an hour or two. But occasionally, a person can take pains in one particular branch. I would like to see a hundred general practitioners keep accurate records of appendicitis, say for a year or two, and then report them. They ought to have the age of the patient, the number of attacks, the line of treatment pursued, and the final results. Then we might come to some conclusion on the medical side of the question.

The kind of microbes, it seems to me, has little to do with the severity. We know in all cases the bacillus coli communis is found, which gives us cases with low temperature, and very deceiving cases on that account, as they are jogged along by the general practitioner for a week or ten days when suddenly leakage takes place into the peritoneal cavity and when the surgeon arrives the patient is beyond help. Cases with mixed infection of bacillus coli communis and staphylococcus pyogenes aureus have a very high temperature and rapid pulse. These are cases that frighten the general practitioner and induce him to call in a surgeon in time. I have also found cases where the appendix had not ruptured and the peritoneal fluid contained staphylococcus albus only, but with the most severe symptoms. How they get there I do not know. We also find bacillus or diplococcus fetidus and many other kinds, so that all around it seems to me that the variety of bacteria or germs has little to do with the severity of the case or the danger to the patient.

---

* Read before the Allen County Medical Society, Fort Wayne, March 20, 1899.

Sometimes an appendix is removed, especially during the interval, which does not seem to be diseased macroscopically; the patient, nevertheless, gives a clear account of having had repeated attacks. If, however, a microscopic examination be made, you will find that the appendix is ulcerated, strictured, etc., and what is better proof, the patient becomes well afterward. Repeated attacks in the same individual vary very much. The first attack may be very light or severe, the second or third may be light or severe, or either of them severe. We can never tell. Many patients are what I call chronic invalids, simply from repeated attacks of appendicitis and the resulting sequelæ.

I think there is no medical treatment that is specific. I think ice or hot applications, or painting with iodin or anything else, are of little value. I do not believe in opium, and still, if the patient is in pain an occasional dose is indicated. Starving the patient, as has been suggested by Ochsner, is certainly efficacious, but does not cure the case; they will have recurrences and require operations.

The diagnosis is generally easy, if the physicians will only look for appendicitis, although the first day the symptoms may point to the stomach on account of the vomiting, or to the bowels on account of the constipation or diarrhea, but after that the well-marked pain in the region of the appendix and the rigidity of the muscles over that part is so clear that a mistake is seldom made. I have operated on cases where I found a malignant growth or a perforation of the bowels, but the mistake was not serious, as this kind of cases equally requires surgical intervention. Morris and Richardson have recorded a large number of cases that show a mistake is made in 3 or 4 per cent. I am perfectly satisfied that I do not make a mistake any oftener and I think every general practitioner in the course of his practice is a splendid diagnostician if he does not make more than this.

The tumor develops as the result of plastic exudate, which walls in the appendix. The appendix becomes attached to the side or the back of the pelvis and finally ruptures, still being well walled in. It sometimes ulcerates through the peritoneum at the side or the back, and the pus works its way upward toward the crest of the ilium, or behind it below the kidney, where it breaks or is opened. These are exceptional cases, patients with the peculiar power of the peritoneum to throw out fibrous exudate, layer over layer, and prevent the rupture into the peritoneal cavity. In fact, the whole question of medical treatment, it seems to me, depends on the health of the individual, especially on his power to throw out the plastic exudate of the peritoneum, and I think that our surgical success depends on the same power. If we operate carefully, restrict contamination of intestines and peritoneum to a minimum, remove the pus, and put in a drain, in a few hours the cavity or the opening we have made is surrounded by plastic lymph and well walled in, and our patient recovers. If, however, the patient's peritoneal secretion is thin and does not coagulate, the bacterial infection is spread all over the peritoneum and we have general septic peritonitis.

I looked over the death record of the city of Detroit for 1899 and I found that 37 cases are put down as having died from appendicitis. There are 54 put down as dying from peritonitis, and though some of the latter cases may be due to pelvic diseases, I am sure that more than half are due to appendicitis, treated with poultices and opium, and finally disposed of with a pious exclamation, "The Lord's will be done."

The death records of these 37 patients were signed by 19 different physicians, and I thought by inquiring from them I might be able to arrive at some kind of conclusion. I received answers from 12, who reported on 25 deaths. Fourteen of these cases had been subjected to operation and eleven others died without any operative interference. As the members of the medical profession who had signed these certificates had been able to properly diagnosticate the cases, and were first-class men in good standing, I thought I might also get further information from them and asked them to give me the number of cases they had had during the year, and how many died with or without an operation. I received reports of 213 cases of appendicitis. Of these, 160 were operated on during the acute attack or during the interval, in fact, at any time when the surgeon thought it was proper. Of these 160 cases, 14 died. This list of surgical cases includes naturally the reports of the principal surgeons and gives a death-rate of about 8 per cent., counting everything—easy interval cases, severe cases, purulent peritonitis, and those actually moribund. The number of cases not operated on, that is, medically treated, were 57, with 11 deaths, giving a mortality of over 20 per cent. From the reports of the physicians in nearly every case, the operation had been urged, but refused by the parents of the patient, or by the patient himself.

I do not want to place these figures forward as positive proof of the result of one line of treatment over the other, because the number is limited. Still, taking them up at random from men who know how to diagnosticate appendicitis, they certainly must be very near the truth. We certainly can not accept the figures of those who do not know what appendicitis is, never diagnose it, and never have a death from it. We must take our statistics from men who are able and progressive and who keep a record of the number of cases; so many were operated on; so many were not operated on; so many died following an operation; so many died without an operation." These statistics from such men must certainly be very near the truth. I would like to have a larger list, but as stated above, one can not expect general practitioners to keep the statistics of all kinds of diseases.

This proves that cases of appendicitis die under medical treatment. This is often denied. I have here the proofs. If I should hunt up all the cases which were put down as peritonitis in the death record, and get the report of them, I feel quite sure that I would increase the above-given record of death of medically treated cases of appendicitis 50 per cent., if not 100 per cent. The general average given by nearly all surgeons is that at least 15 per cent. of appendicitis cases die; 15 per cent. never have a recurrence after the first attack, and about 60 per cent. have recurrences and die off, one by one, at the rate of 15 per cent., unless relieved of their appendices. In conclusion I desire to make the following points:

1. It ought to be a general rule that every case of appendicitis should be operated on as soon as the diagnosis is made, but when it is the first attack and very mild, or no proper facilities are at hand either to perform the operation or to take care of the patient afterward, it is often good policy to wait and watch the case.

2. In cases of second or subsequent attacks, however, the patient should be sent to a hospital, even though it is at quite a distance—unless good facilities can be had at home—and an operation promptly perf

3. Statistics of cases operated on as they

good, bad and indifferent, by experienced surgeons, give a mortality of only 8 per cent.

4. Statistics collected by general practitioners who are able and up to date, and who advocate surgical interference, show that medically treated cases have a death-rate of at least 15 to 20 per cent.; that at least 60 per cent have recurrences; while the cases operated on are absolutely cured.

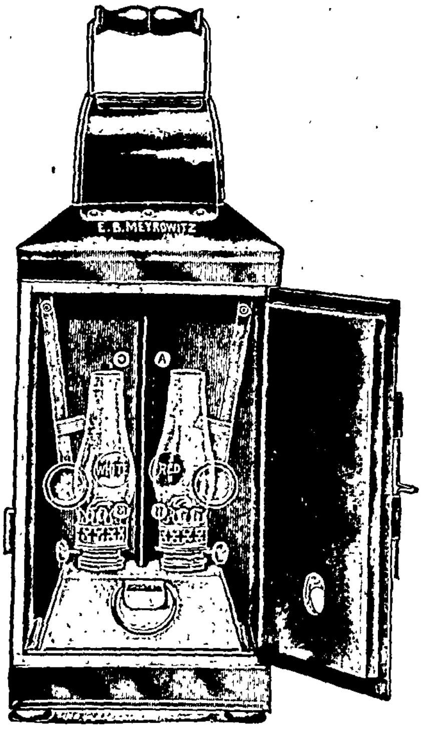
IMPROVED LANTERN FOR TESTING COLOR PERCEPTION.*

CHARLES H. WILLIAMS, M.D.
BOSTON.

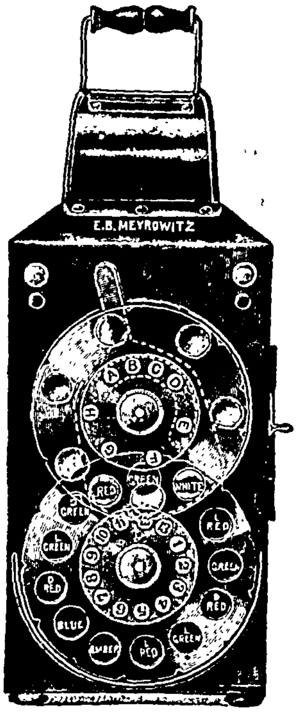
This lantern is an improved form of the one I showed at the meeting of this Section last year. It puts in more practical form the principle which has for many years been carried out on the railroads of Holland, where a color-test both by worsted and a lantern, of more complicated construction, is required. The lamp is arranged with two burners, and in the front of the lantern are two openings so that two colors can be shown at one time, as red and green, two reds, or two greens of different shades, a red and white, etc. In this way a comparison of signal colors can be had, as is often the case in service; or, by moving a diaphragm one light can be cut off, and only one color at a time is then seen. There are thirteen colored glasses, and variations of intensity of color are arranged by a difference in the shades of the colored glasses and by combining them with smoked glasses placed in another disk. Also, the size of the colored area can be varied by a diaphragm moving between the disks.

The lantern is square in shape, about a foot high and six inches on each face. On its front are two revolving disks. The lower carries thirteen glasses, five reds and five greens of different shades, including a red glass that with the spectroscope is seen to transmit a certain amount of green light in addition to the red, and a green glass that transmits a certain amount of red in addition to the green, although not enough in either case to interfere with the general color of the red or green glass when seen by a normal eye. Such glass is often found in signal lanterns, and if a person is defective in his color perception for red and green there is more chance of his mistaking the color of such signals than when the glass transmits light of a purer shade. In addition to reds and greens, this disk carries one yellow, one blue and one colorless glass. The upper disk has several empty spaces and three different shades of smoked glass, and any of these can be combined with any of the glasses of the lower disk to give a variation in the intensity of color. Between the disks is a movable diaphragm arranged so that colored areas of three different sizes can be shown, or so that one light can be completely cut off.

Inside the lantern are two movable pieces of ground glass, which can be put in the path of the light or withdrawn, and the combination of these ground glasses gives very much the same effect as is produced by fog and smoke on the appearance of the colored signal lights. The darker smoked glass should not be used with the smallest opening of the diaphragm, for it will reduce the light too much, but with the larger openings any of the glasses may be used. With each colored glass is an illuminated number, and with each smoked glass a letter, illuminated by the lamp of the lantern, so that the examiner can see it, but screened from the person being examined. In this way it is easy to keep a record of the color shown in every case, together with the name given to it by the person tested. This lantern test is easy to make either by day or night, a darkened room



being used by day. These colors do not fade. They resemble very closely the colors and appearance of signals in actual use; and will detect small defects of color perception in the central portion of the retina that may be entirely overlooked by the worsted test.



During the past year I have had four cases who passed the Holmgren test without difficulty but who made so many mistakes with the reds and greens of the lantern as to show that they were unable to distinguish correctly the true colors of signal lights seen at the usual distances. One of these cases who had been twice examined with the colored worsteds and passed as having satisfactory color perception made the following mistakes with the lantern: No. 2 (green) he called red; No. 4 (green) he called red; No. 5 (red) he called yellow; No. 8 (red) he called green; No. 9 (green) he called red; No. 10 (green) he called red; No. 12 (green) he called red; and No. 13 (white) he called red. On testing him in my office he made some of the characteristic mistakes with the colored worsteds, but his former examiner had passed him, and I do not think this mistake would have been made if the lantern test had been used in addition to the worsteds.

---

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The lantern gives some information that we do not get with the worsted test, especially in regard to small defects in the central portion of the retina, in regard to the recognition of signal colors when affected by fog or smoke, and in regard to the ability to give correctly the proper name to the color shown. On the other hand, the test with the colored worsteds, in which the colors are selected by comparison with certain test colors, as proposed by Professor Holmgren, and which when properly made is a true test by comparison of colors in which no names are used, gives some information that the lantern does not give. Both tests should be used in order to get satisfactory results and make sure that all the dangerous cases of defective color perception have been discovered.

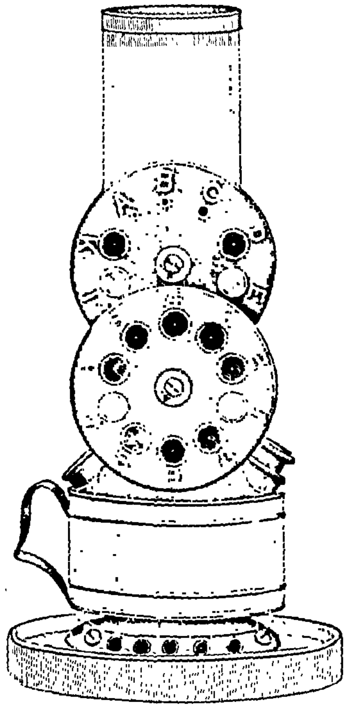
IMPROVED METHOD OF TESTING COLOR PERCEPTION.*

WILLIAM THOMSON, M.D.
PHILADELPHIA.

Dr. Williams' remarks leave but little to be said in favor of the use of a lantern for examination of the color sense. In the system in use of the Pennsylvania Railroad the lantern of Donders has been advised for the testing by the ophthalmic expert, but I am now convinced that a test of this kind should be used in conjunction with the colored wool stick by all the examiners who act under the direction of the division superintendent. Two-fifths of the time of a railway employee's life is spent in governing his action by colored lights by night. The lantern furnishes the test. It also gives us the means of detection of central scotomata, or the color defects caused by central amblyopia induced by tobacco and alcohol. It consists of a small kerosene lamp, or spring candle-stick on which can be placed an asbestos chimney seven inches in height. This can also be placed over an argand burner or an electric light. Two disks of metal are attached so that they can be partly superimposed. Each disk has ten openings, the upper marked by letters from A to K, the lower by the figures from 1 to 10. They are too small to be distinguished at the proper distance. The lower disk has its openings, 10 mm. in diameter, filled by the four colored glasses used on the roads, viz., white, red, green, and blue. This is for the examination in chief, the upper for the cross examination. The upper disk has four openings, from 1 to 10 mm., which can be brought over the lower glasses to diminish their size. The other openings have dark London-smoked and ground glass to indicate the effect of storm, snow, rain, or fog. G, H, and I are efforts at imitation of confusion colors, and are called and seen as white by the color-blind. They are light smoke, pink, and blue-green to the normal eye. The last is K, a cobalt transmitting both red and blue light, both evident to the perfect eye, but appearing as blue only to the color-blind. The yellow color of the kerosene flame prevents the blue from being well seen in the pink and blue-green openings, which therefore appear white to the color-blind. The examination is made in a dark room, the man being placed 5 meters away. As the examiner turns the disk, the man is directed to call out the colors presented. Any mistakes are at once detected and if it be required can be recorded on proper blanks by using the figures or letters employed.

The degree of color defect can be determined by the use of the openings from A to D. A man with full color sense should perceive the colors when the smallest openings, 1 mm., are used. If he fails, the larger ones are used, and if at 5 mm. he fails to see the light through 10 mm. opening he is much under standard, having only 1/10; by placing him at 1 meter he may again fail and show a defect of 1/50.

No man should pass who would call the red signal, green or white; the green one, red or white; or the white one, red or green. The man should also be asked to tell what the lights indicate as signals, the white, safety; green, caution; red, danger, halt; the blue, the inspection light, indicates that a car should not be moved showing a blue light.



To enable the officers of the road, the examiners or others, to appreciate partly the defect of color-blindness the chimney may be placed over an alcohol lamp having mixed with the alcohol a quantity of common salt. The colors are then all destroyed for those having normal sight. The illumination of the color stick, or of other colored wools in a dark room by this yellow light apparently destroys the colors, and closely imitates the defect of the color-blind. With the addition of this convenient lantern to the color stick the so-called Pennsylvania Road System[1] may be regarded as more complete. It has been in use for twenty years on that road, and has been adopted by other corporations estimated to control in all 150,000 miles of track.

CUTANEOUS MANIFESTATIONS IN DIABETES MELLITUS.*

S. SHERWELL, M.D.
BROOKLYN, N. Y

In company with its direct analogue, histological as well as in some degree functional, the skin suffers many insults from the glycosuric state, subjectively, and often bears decided objective symptoms resulting therefrom.

It never should be forgotten, though it often is, to what large degree vicarious elimination of morbid and effete matter is carried on by the skin, in its natural effort to relieve other organs in the human economy, more particularly the larger splanchnic glands, as for example the liver and kidneys, as evidenced in those cases by icterus, uridrosis, etc.

In fact, the integument must really be recognized, taken in its totality, as the largest eliminating organ of the body, which perhaps is only another way of putting the aphorism of Æsop, "that there is nothing like leather."

Skin symptoms are frequently the first to call our attention to the presence of the morbid condition which is being considered in its various aspects by this Association, and which from its most noteworthy and constant index, presence of sugar in urine, we call glycosuria.

To enumerate all the subjective and objective phenomena which this morbid condition may produce in and on the skin would almost seem like having to give a list of the ordinary diseases thereof, certainly of all the so-called primary lesions. I shall content myself with commenting on a few of the more usual, and easily recognized—though not always so by the general practitioner—and one or two of the rarer manifestations. This list may be made out in the order of relative frequency, as follows:

1. Xeroderma, or a condition of dry skin.
2. Pruritus, without any, or at least any noteworthy, objective lesions, the genital regions in both sexes apparently suffering most.
3. Eczemas, partly neurotic, at other times catarrhal, having as chief seats the genitals, and flexures of the body and limbs.
4. Furunculosis, often general in character, but sometimes regional. This is often the case with the very common occurrence of its analogue—carbuncle. The seat of preference seems to be the extensor aspects of the body, as nucha, gluteal region, etc.
5. Conditions of erysipelatous manifestations and gangrene; late symptoms as a rule will not be considered here, as they belong chiefly to the domain of general surgery.
6. Xanthoma diabeticorum, a disease accompanied by formation of xanthomatous new-growths, often in immense quantities, and more particularly over extensor surface of body and limbs.
7. Possibly, the recently recognized and not much investigated "blastomycetic dermatitis," in which tumors looking like verrucous lupus, or the so-called "tuberculosis verrucosa cutis," become fungoid in character, and on microscopical examination are found to be filled with the fungi of saccharine fermentation. There have been very few cases of this last disease noted or described, not, I think, over twelve in all. I have lately been in communication with its closest and earliest observers—Drs. Hyde and Montgomery, of Chicago—and have begged them to take its possible connection with the glycosuric state into consideration, which has hitherto been but imperfectly done; they have considered it a good suggestion. It would seem to me, from the nature of the cryptogamic parasite present, to be an interesting point for consideration.
8. Dermatitis herpetiformis—Duhring's disease.

In considering the few points given above in something like sequence, I would say that the dry skin of glycosurics is capable of a simple explanation. The parched lips, the dry throat, the dry condition of the mucous membrane, from excessive excretion of water by the kidneys, are their own explanation. This condition should always excite suspicion in the medical mind. As to their relief as far as practicable, the means are obvious, viz., local treatment, and appropriate diet and medication.

The second in order, pruritus, is always suspicious, and the urine should be carefully studied, not only that of the morning, the so-called "urina sanguinis," but that obtained after a full, rich evening meal. Sometimes the latter shows considerable sugar, when that of the morning does not. A list of palliative and curative remedies is altogether too long to be treated of here. Naturally, always the chief objective point is to relieve the diathetic condition.

Eczemas that occur so frequently, especially in the sites mentioned, may be dismissed briefly. Often the fermentation parasitic element, as well as its congener, the trichophyton, can be detected around the genitals. Lotions mildly parasitic in character usually seem to act better, and are cleanlier than salves in these conditions.

Furuncles and carbuncular states need appropriate treatment. I need not give any specific recommendations; the recognition of the cause and the attention as needed to the local condition are generally plain. I will, however, say here that in conjunction with local treatment mild dosage with arsenic and the use of Startin's old tonic are of manifest and great advantage.

I shall not consider the purely surgical questions of erysipelas and gangrene, as the gentlemen preceding me have done it so fully. I would say, however, that the only cases I have ever seen of erysipelas of the fauces and upper air-passages occurred in diabetics.

The sixth condition, that of "xanthoma diabeticorum," is now a well-recognized and striking disease of the skin, and I may be pardoned perhaps for a few moments in its description, as I very lately have had a very striking example of this condition, in the person of a woman aged about 40. [Photographs were exhibited.] It will be seen that she is covered with an immense number of papular, tubercular, and nodular tumors over extensor surfaces and limbs. These in the natural light appear of a yellow—xanthomatous—color and almost exactly resemble the tumors one sees around the eyelids, especially in the upper lid around and near the internal canthus.

This woman has now suffered nearly six years with this affection, always constantly present, but decreasing somewhat in summer, and every year becoming relatively worse. The disease in question has now been recognized for about fifteen years, first, I believe, by Malcolm Morris, of London. There are only about thirty-five cases reported in dermatological literature, of which two are my own. In all these cases glycosuria, generally of a pronounced character, was found. In the case above referred to, over 10 per cent. of sugar was present. In fourteen days of anti-diabetic diet alone she improved at least 30 per cent. in general condition. The case was treated last winter. In about two months, under that regimen and a little medication, the tumors had entirely disappeared, not even a macular pigmentation being left. The sugar decreased *pari passu* with improvement of her condition, and now, as I see her about every fortnight, I find the sugar reaction is very slight. Objectively, as well as subjectively, to all intents she is a well woman. I presume, however, indiscretion in diet, or laxity in treatment, would allow the disease to return.

DIABETES MELLITUS IN CHILDREN.*

HENRY DWIGHT CHAPIN, M. D.
NEW YORK CITY.

One who proceeds to investigate this subject will be at once surprised at the little that has been written on it. A large portion of the works on diseases of children say nothing at all about this disease, while others treat of it in a few lines. It is undoubtedly a rare affection in children, yet it does occur, and certain phenomena in connection with the disease should lead us to be on the lookout for it. Gerhardt has recorded 111 cases at various ages from 11 months to 16 years. In the last volume of Keating, 1895, a case was reported in which grape sugar was found in the liquor amnii of a diabetic pregnant woman. Unfortunately the infant was deadborn; but Roosa meet with a similar case in which the infant lived long enough to have the urine analyzed. In this case the examination of the urine of the baby gave a negative result, although the mother's urine and the liquor amnii showed the presence of glucose.

I report two cases which I have seen during the past year in consultation. The first one was seen with Dr. Charles Jackson, of New York, last October. The patient, a boy of 4½ years, had always been delicate, but had never had any special disease. He was taken to see the Dewey parade, and was perhaps unduly exposed and fatigued. Following this he seemed to be out of condition, and to have a slight fever. A physician was called in, who diagnosed malaria, and the child was accordingly put on quinin, but did not improve. Dr. Jackson was then called in, and found no cause for the failing health until he examined the urine and discovered that it was loaded with sugar. The child passed from 105 to 110 ounces of urine daily. I was called in consultation on October 10, Dr. Jackson having first seen the case on October 6. I examined the case very carefully, and could find absolutely nothing in any of the organs to account for the atrophy of the child. There was no evidence of tuberculosis. I gave a very bad prognosis. The child died three days later. There had been no other symptoms except loss of appetite and interest, and emaciation. The course of the disease was apparently about three weeks.

The other case I saw in consultation with Dr. McPhee, of Harlem. This occurred in a boy of 6 years, and the duration of the disease was between three and four weeks. On examination, I could find no cause for the rapid atrophy evidently taking place. The only feature of the physical examination was hydrocele of the right tunica vaginalis. When I saw the child he was in a state of semi-stupor; it could hardly be called coma. A few days later Dr. McPhee sent me word that the child had lived four days after the consultation. The coma had diminished following a free sweating and relaxation of the bowel; then it had gradually deepened until the end. In both of these cases the urine contained approximately 5 per cent. of sugar. The sugar continued to be present in about the same quantity up to the last. The respirations rose to 56, and the temperature to 101.2 F., while the pulse ranged between 110 and 140 during the last few hours of life. The only nervous manifestation was a peculiar reaching movement of the hands. The pupils responded to light. His emaciation was so rapid that it could be distinctly noted in the four hours elapsing between the visits of the attending physician.

In my experience, I have met with only a very few cases of diabetes mellitus. I believe we can sum up our knowledge of this disease very briefly. First, I would call attention to its exceeding rarity. I have the urine examined of all the children in the babies' wards of the New York Post-Graduate Hospital, and also in the Willard Parker Hospital, and of the Riverside Hospital; yet it is exceedingly rare to find any sugar in the urine. The next point that I should make is that the disease is exceedingly fatal in young children. Why this is so, I am at a loss to explain. In both of the children referred to there was no evidence of assimilative disturbance, and the children had been in a state of good nutrition.

In looking up the literature I found one case which was reported to have recovered. In the light of our present knowledge of this disease, and particularly what we have just heard about testing for glucose in the urine, I should doubt if in this case the diagnosis was correct.

The third point I should make is that this disease in children is accompanied by exceedingly rapid emaciation. A few weeks ago a little girl of 10 years was sent to me, a diagnosis of diabetes mellitus having been made. The mother stated that three or four specimens of the urine had shown sugar. A specimen was sent to me, and I failed to find sugar by Nylander's test. I found the child to be fairly well nourished, and during the four or five weeks that the glycosuria was said to have lasted she had not failed materially. I therefore felt justified in stating that the child was not suffering from diabetes mellitus. Subsequent examinations have failed to show any glycosuria. I believe whenever a child is brought to the physician with a rapid atrophy he should examine the urine for sugar. I wish to emphasize the statement that this is one of the diseases of childhood which produces rapid atrophy.

Vacancies in Medical Corps of Navy.—A naval medical board of examiners for examination of candidates for admission to the medical corps of the navy is now in session at the Naval Laboratory, Brooklyn, N. Y., and will remain in session for several months. There are now seventeen vacancies in the list of assistant-surgeons. Congress at its last session passed a law taking assistant-surgeons out of the steerage and making them ward-room officers as soon as they entered the service, giving them the rank of junior lieutenants and the pay of assistant-surgeons in the army. Candidates must be between the ages of 21 and 30. Circular of information can be obtained on application to the surgeon-general of the navy, navy department.

INFLUENCE OF SEA-AIR AND SEA-WATER BATHS ON DISEASE.*

W. BLAIR STEWART, A.M., M.D.
Late Assistant Professor of Pharmacology and Physiologic Action of Drugs, Medico-Chirurgical College; Surgeon to Atlantic City Hospital; Member American Medical Association; American Academy Medicine, Etc.
ATLANTIC CITY, N. J.

The purest air in nature is that found on the high sea after traversing hundreds and thousands of miles of pure sea-water, uncontaminated by smoke, dust, and the exhalations of cities. Saline mists and fogs clarify, purify, ozonize, and vitalize the air. Sea-air is tempered by its surroundings; in summer it is cooled by radiation from the lower water-temperature and in winter warmed by the higher water-temperature. Moisture is also taken up by it and a doubtful infinitesimal per cent. of salt. The so-called trace of iodin is very questionable and can not be positively demonstrated. Sea-air is classed as an alterative by some, but not on account of its supposed iodin.

Outside of an island in mid-ocean, Atlantic City is probably situated in the best location for pure sea-air; better than any point on the eastern coast of the United States. Its geographical location is on an island of pure sand, five miles from the mainland, and twenty miles seaward of the head of tide-water; at a point of a bend in the coast line, thirty miles northeast from Cape May and seventy miles from New York bay, where the fresh waters mingle with the ocean. It is surrounded by a body of salt water, uncontaminated by fresh water streams, and entirely free from malarial or any other paludal poisons. The salt meadows between the island and the shore are overflowed by tide-water twice in twenty-four hours. The gulf stream is about 125 miles from the shore and tempers the surrounding sea-water and the air so that in winter it is from 10 to 20 degrees warmer and in summer from 10 to 20 degrees cooler than interior cities. High winds are less frequent than at other points. Sea-air mixed with sea-fog is not injurious to most cases, as it contains no noxious elements, is non-irritant, and quite equable in temperature. The two great effects of sea-air are upon the nervous system and digestion.

Coming from the dense air of cities and the rare air of high altitudes, respiration and heart action are slowed, at once reducing the consuming energy of the body and lessening waste. Sea air is dense and ozone-laden and, therefore, it increases the oxidizing power of the blood and is Nature's best remedy for anemia. It assists in fighting the malarial parasite, and will, in time, eliminate the poison from the system. Malarious subjects come to the shore and often overload the stomach, overheat themselves, sit in the cold, indulge in promiscuous sea-bathing, thus bringing on acute paroxysms, and then blame Atlantic City. If care be exercised, the usual chill may often be avoided. Night air here is not injurious to these cases. Patients with heart disease do well here, as less work is thrown on that organ and oxidation is carried on better than in higher altitudes. Cardiac dropsy sometimes improves for this reason.

Convalescents from disease and those who have been debilitated, over-worked, and confined to rooms and offices, invariably improve, if they live hygienically, and follow proper dietetic rules. The effects of sea-air are stimulant at first, and add vigor and tone. Appetite is increased decidedly and a drowsy feeling is almost sure to follow its satisfaction with a refreshing night's sleep. Many business men come to Atlantic City periodically to get a full night's rest and sleep. Strumous and tubercular children and adults will improve rapidly if they live in the sea-air and follow proper dietetic rules. Many such cases have been apparently cured here with little medicine. Tuberculosis in its early stages is amenable to treatment in sea-air and sunlight. Such cases should invariably act under physicians' advice. Consumption in its later stages is best at home, as it will not improve here. Many cases of bronchitis are permanently cured by sea-air. There is less danger of pulmonary hemorrhage in sea-air at sea-level than in high altitudes, owing to the 15 pounds pressure to the square inch here and the density of the air; in higher altitudes the internal blood-pressure is not so readily equalized at first and often gives rise to hemorrhage. Many cases of asthma and emphysema do well here, while others are made worse. Trial only can demonstrate. Hay-fever almost invariably disappears in sea-air, but when the wind comes from the land it may be aggravated.

It is a mistaken idea to think that one can not catch cold at the seashore, but one coming here with an acute cold will throw it off more rapidly than in the interior. Some people cure their colds by sailing every day and living on the board walk. Hot and close rooms are to be avoided at the seashore, as they are productive of colds and depression. Laryngitis and acute catarrhal troubles do well at the shore if properly managed; but do poorly, if smoking, late hours, and carousing are encouraged. Acute lobar pneumonia is rarely seen in Atlantic City, and when it is it usually runs a very mild course. Cases of Bright's disease and diabetics in the early stages do well. Contrary to the writings of some, many cases of eczema and skin troubles improve perceptibly and are cured in sea-air. This is particularly noticeable in young strumous children. Digestive troubles are very amenable to treatment if proper rules are followed.

Neurasthenics do particularly well in Atlantic City in the fall, winter, and spring months, but not in July and August, when the large crowds are here, unless they go to parts of the island that are isolated. Insomnia soon leaves and nerve tone rapidly improves. Melancholia and insanity are usually aggravated by sea-air. Hysteria may or may not be improved, acording to the cause. Neurasthenics may find the first few nights here unpleasant and restless, but these soon give way to sound sleep. These cases should be closely watched to prevent abuse of surf, hot, and cold sea-water baths.

Sea-water is a physical and chemical mixture and varies in the quantity of constituents in various localities. Its strength is affected by admixture with fresh water; the depth from which it is taken; the air, temperature, and ocean currents. Chemists say that it contains about 3.5 per cent. solids and 96.5 per cent. of water. The main solid constituents are sodium chlorid (2.7 per cent.), magnesium chlorid (0.3 per cent), magnesium sulphate (0. 2 per cent.), calcium sulphate, calcium carbonate, potassium chlorid, magnesium bromid, traces of carbon dioxid, iodin, etc. One chemist figures 3½ grains of bromin in 100 pounds of sea water. Salt baths are necessarily medicated baths and must be taken under limitations by the sick and well.

No form of sea-water baths is so generally used and abused as the surf bath. It combines the effects of cold and violent exercise. On entering a cold bath there is a shock, with contraction of the skin and muscles, pallor, quickened respiration and heart action, slight depression, shivering, and reduction of temperature. This lasts for a few seconds or minutes, when a reaction sets in. Respiration slows; the heart acts less vigorously; a general glow comes to the skin, and a sense of invigoration or stimulation follows. If continued beyond this point, depression again follows with weakened heart action, blueness of skin and lips, shivering and chilling, and a feeling of prostration and drowsiness. If still persisted in, coma, syncope, throbbing headache, apoplexy in the aged, congestion of the internal organs, subnormal temperature, or death from general depression will follow. All these symptoms are intensified in the presence of exercise and in moving sea-water. It is well known that moving water will abstract much more heat than still water.

---

*Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Wave force and pressure varies with the depth of the water, direction of the wind, ebb and flow of tide, and the pressure of breakers. Exercise beyond the breakers where the waves regularly follow each other is not so violent. A slight jumping or rising motion is sufficient to float over the wave without much shock; but if one stands and receives its full impact the shock is terrific. This soon produces physical strain and soreness. Floating and swimming beyond the breakers is quite invigorating. Most force is expended by bathing in the breaking waves (breakers), and it is practically a series of blows that soon exhaust. Many prefer the washing effects of the broken wave and return flow to be obtained by lying just to the shore side of the breakers. This is the least exhausting form and best suited to children.

Many do not experience a reaction after entering the ocean and come out of the water with so much depression that days and sometimes weeks are required to recover. Such subjects should never take surf baths nor even cold tub baths. The proper time to leave the surf or cold bath is during the height of exhilaration or reaction, which comes on in from three to fifteen minutes in the strongest subjects. Leave the bath and immediately go to the bathroom and rub briskly with a coarse towel and then rest. Many lose the real benefit of the bath by exercising too freely afterward. Daily bathing is usually too depressing to the average person; every other day is best. If stimulants are necessary to bring about reaction it is harmful and should be avoided. It is my custom to begin, in many cases, with tepid or cool baths in the tub or pool and gradually accustom the patient to cold before permitting a surf bath. The temperature of sea-water at Atlantic City varies from 65 to 75 or 80 F. in summer, and from 45 to 60 in winter.

It is unwise for any one to enter the surf bath before his morning meal and never until three hours have elapsed after eating. Cold baths retard digestion. Never come from the water and go directly to meals until reaction has been thoroughly established. Great excitement of any kind is a contrary indication to entering the water; also immediately after exercising freely, or indulging in intoxicating drinks, as alcoholics prevent healthy reaction. Patients with bad varicosities are liable to rupture them in the surf. Children under three years and real old persons should never bathe in the surf or cold bath, as their resisting and reacting power is too low. Never force young children into the ocean, as it is productive of harm. Other contraindications to surf bathing are advanced heart disease, atheroma, bronchitis, menstruation, advanced Bright's disease, pregnancy after third month, rheumatism, acute gout and acute diseases.

Mild forms of neurasthenia, insomnia, anemia, indigestion, and debility by too close confinement are most benefited by surf or cold sea-water baths. Tepid and cool salt baths are best for convalescents, those whose reaction is very poor, and young children. Sea-water baths act upon metabolism much more than fresh water. Tissue oxidation is increased and elimination much improved. Weight at first decreases but later increases.

Warm salt baths at 85 to 97 F. are used to encourage slight perspiration, relax the skin, reduce internal congestions, and carry off a part of the body poisons through the skin. These baths should always be taken in a warm room and never prolonged over ten minutes. They should be followed by a good rub with alcohol or cocoanut-oil and a rest of at least one hour. Many prefer this bath at bedtime to induce sleep. Some aged neurasthenics and those with low resistive power do best with these baths. My policy is to give the salt bath only every other day. When continued too long there is headache, flushed and throbbing temples, great prostration, languor, and rapid elevation of temperature, and body oxidation is reduced. Warm baths are used in all cases where relaxation of the sudorific glands is required, and in reduction of many forms of pain. The hot sea-water bath is rarely of much use except in uremia and to produce profuse perspiration. The practice of so many people taking warm and hot sea-water baths indiscriminately is productive of much more work for the physician and harm to themselves. Untrained attendants will always put your patients into baths that are too hot and keep them there too long. It is always wise to lay down explicit rules for each case and enforce them. Never tell a patient to take warm or hot sea-water baths and then trust to his knowing how to take them.

THE IDENTIFICATION OF DEXTROSE IN HUMAN URINE.[*]

HEINRICH STERN, PH.D., M.D.

Professor of the Diseases of Metabolism, College of Physicians and Surgeons, St. Louis; Visiting Physician, New York Red Cross Hospital; Attending Physician, St. Elizabeth's Hospital; Member American Medical Association; Member American Chemical Society; Fellow New York State Medical Association, etc.

NEW YORK CITY.

Dextrose, in insignificant traces a constituent of almost every normal urine, can be readily demonstrated in the renal excretion, provided it occurs in sufficient amounts. The moment, however, that urinary grape-sugar is detected by the more commonly employed methods, it indicates a deviation from the normal systemic state. Thus, in glycosuria, no specific pathologic element makes its appearance, but a regular constituent of excessively increased quantity. While, as a rule, glucose can be positively identified in urines containing 0.5 per cent. or more of it, great difficulty in this respect is often experienced when smaller amounts are present.

Glycosuria, a well-defined condition, resulting from or concurring with some systemic anomaly, is most always recognized by the painstaking physician; yet, certain systemic occurrences—physiologic or pathologic—may be erroneously diagnosed as glycosuria, when, as a matter of fact, grape-sugar in appreciable quantities was never discharged by the urine. Coinciding with pseudo-glycosuria, there may be other symptoms apparently pathognomonic of the diabetic state; thus, I know of a number of instances where individuals underwent treatment for diabetes without ever having been subject to this affection.

---

[*] Read at the Sixteenth A[illegible] fth Branch of the New York State [illegible] lyn, May 22. 1900.

Glycosuria is frequently noticed first by the medical examiner of a life insurance company, and there is no reason to doubt the correctness of the diagnosis in the great majority of instances; however, many spurious cases, which came under my observation, were originally interpreted as glycosuria by life insurance examiners.

This pseudo-glycosuria, or diabetes, which has absolutely nothing in common with the true condition, debars the applicant from obtaining any life insurance.

In the *Medical News* of June 4, 1898, under the title of "The Life-Insurance Company and Its Encroachment upon Personal Rights," I referred to the following instance: "A colleague, aged 45 years, of good physique, good family history and good habits, applied for life insurance in one of our companies. He was rejected on account of diabetes. Numerous examinations of his urine did not reveal to me any glucose, nor does his general condition warrant the assumption of a glycosuric or diabetic state. The applicant himself was, and still is, in the habit of examining his urine from time to time, and as yet has never detected any grape-sugar or any other abnormal constituent. The inefficient examiner was evidently mistaken and negligent. Possibly his Fehling's solution had deteriorated; possibly the few pieces of chemical apparatus used were not previously thoroughly cleaned. No matter what caused the apparent copper reduction, it was this official's duty to apply at least one control test to ascertain the presence of glucose. Had he done so the rejection of the applicant on account of diabetes could not have occurred. I have selected this case from a number of others which I have in mind, as it occurred recently, and as the applicant is a well-informed, conscientious and trustworthy physician."

I repeat, that in the case just alluded to, not a single abnormal urinary constituent was present, that transitory glycosuria, as experimentally proved, had to be excluded, and that the reduction of the copper solution was due to either its deterioration, or to unclean apparatus, or to inexperience of the examiner, or to any two or all of these possibilities together.

Gross negligence, to say the least, is often exercised when testing for dextrose in the urine. I distinctly recall three cases designated as "diabetes" by life-insurance examiners, where the reduction of copper in alkaline solution was caused by tartronyl-cyanamid in excess. Had the analysts performed one or two control tests, such an error would never have occurred. Some instances of apparent glycosuria were in reality such of creatininuria. The application of the Weyl-Salkowski test for creatinin left no doubt as to the true reducing factor.[1]

A case of supposed diabetes referred to me for treatment in 1895 turned out to be one of urobilinuria. Urobilin, which was present in greatly increased amounts, imparted to the urine reducing qualities; hence, Trommer's test, when applied by the family physician, gave apparently positive results. A few control tests divulged the non-presence of glucose, and urobilin in rather abnormal quantity was detected by two very simple processes.[2]

Another case of assumed diabetes which I encountered proved to be one of intestinal hyper-putrefaction, with accompanying indicanuria. Evidently the family physician who rendered the original diagnosis was only acquainted with the bismuth tests for the detection of dextrose, for urine rich in indican possesses the property of reducing the bismuth salt. It was an easy matter to disprove the occurrence of glycosuria, and to point out indoxyl-potassium sulphate as the reducing substance.[3]

Alkaptonuria, so-called, is of comparatively infrequent occurrence; however, when it is first recognized in an applicant for insurance or in a patient, it is most always mistaken for glycosuria. The reducing effect of the alkaptonic acids upon alkalin copper solutions is similar to that of dextrose.

These acids, however, do not undergo fermentation, and do not reduce bismuth subnitrate like glucose, although they may cause a precipitation of a brownish substance; alkapton does not reduce picric acid in the presence of a free alkalin hydrate, and does not respond to the phenyl-hydrazin and polariscopic tests for dextrose. Exposed to the air, its solution resumes a much darker tint. A young man, aged 19, in 1894, was rejected by one of the large New York life insurance companies on account of what they pronounced "diabetes." The applicant's medical adviser, who felt satisfied as to the presence of glycosuria and some of its apparent concomitant manifestations, instituted a rigid antidiabetic diet and prescribed a preparation of opium. The supposed glycosuria was not diminished at the end of four or five months' treatment, and the patient, finding himself growing gradually weaker, called in some other practitioners, who were of unanimous opinion as to the nature of the affection. A consultant of great prominence, not questioning at all the correctness of the diagnosis made by the other physician, finally advised a prolonged sojourn at Carlsbad. An analysis of the patient's urine made soon after his arrival at Carlsbad revealed the presence of 2.5 per cent. of glucose. Uranalysis, performed by the same chemist, just before the patient's departure from that town, demonstrated 0.5 per cent. grape-sugar only.

---

[1] Weyl-Salkowski test for creatinin. Reagents. 1. Ten per cent. solution of sodium nitroprussiate; 2. Ten per cent. solution of sodium hydrate: 3. Acetic acid.

Detection: If to a specimen of urine containing creatinin a few drops of the freshly prepared sodium nitroprussiate solution and some of the sodium hydroxid in solution are added, a transitory ruby discoloration of the urine, soon turning into yellow, is produced. Addition of acetic acid and subjection to heat when the yellow color is obtained imparts to the mixture at first a greenish and then a bluish tint. Finally, a precipitate of Berlin blue is thrown down. The reaction will occur only if the mixture has been heated.

[2] *a.* Detection of urobilin: Reagents—Ammonium hydroxid and solution of chlorid of zinc. The urine, rendered alkaline by the addition of ammonia, is separated by filtration from the phosphatic deposit. To the filtrate, a few drops of a chlorid of zinc solution are added. The occurrence of a green fluorescence denotes the presence of excessive amounts of urobilin. The mixture, on spectroscopic examination, shows the characteristic absorption band on the intersection of green and blue, between Fraunhofer's lines *b* and *F*.

b. Reagents—Chloroform, alcoholic solution of chlorid of zinc, and absolute alcohol. Detection: The urine and a few c.c. of chloroform contained in a test-tube, are repeatedly, but gently, shaken together. After separation of the chloroform, one drop of an alcoholic solution of chlorid of zinc is added to it. If urobilin is present in appreciable amounts, a rose-red discoloration with green fluorescence will ensue. In case the mixture has become turbid, it will clarify on the addition of absolute alcohol. (E. Wirsing: Verhandlungen der Würzburger phys. med. Gesellsch. N. F., xxvi, No. 3).

[3] Jaffé's test for indoxyl—potassium-sulphate. Reagents—Hydrochloric acid; concentrated, freshly prepared solution of chlorid of calcium, and chloroform or ether. To 10 c.c. of the albumin-free urine in a test-tube, add an equal volume of concentrated hydrochloric acid and heat. Next add, drop by drop, of a concentrated, freshly prepared solution of chlorid of calcium until the maximum blue tint is reached. Following this the mixture is well shaken with 2-4 c.c. of chloroform (ether, Salkowski). The chloroform-extract of indican, on standing, settles on the bottom of the test-tube, and the depth of its color may serve as an approximate indicator of the amount of indoxylpotassium sulphate contained in the urine.

After an examination of the young man's urine made by me I stoutly contended that its copper-reducing constituent was not dextrose, but one of the alkaptonic acids. Numerous analyses of the same urine, which I subsequently performed, confirmed my original assumption in every instance.[4] I have examined the urine in question prior to the gentleman's departure for Europe and also soon after his return, and I assert that he never excreted any urinary glucose before he left nor ever after he came back. The inferences to be drawn from this instance are obvious, and this case drastically illustrates the methods in vogue at certain continental watering-places.

Negligence, above all, is responsible for the errors in diagnosis in the instances heretofore cited. Such mistakes are never made by conscientious and painstaking examiners, for, if they do not feel themselves competent to definitely diagnose a given case, they invite efficient assistance, and thus untold anxiety and many an unjust rejection may be averted. A patient is free to change his physician when he has found him incompetent, but this advantage is denied him when he is an applicant for life insurance, for, in this case, the medical examiner is virtually an autocrat, whose opinion—"Roma locuta, causa finita"—leaving the benefit of the doubt always to the company employing him, is decisive. In many instances the life-insurance examiner is not chosen for his ability and reliability in matters medical. On the other hand, even if all necessary precautions are taken, it is not always an easy task to positively identify grape-sugar occurring in small, but still, pathologic, amounts. This is due to the limited resources for chemic research at the disposal of the general practitioner and his lack of special training for more exact analytic work.

The delicacy of a test for glucose is dependent upon the character of the latter's solution, hence, a test for dextrose, in point of sensitiveness, responds differently if applied to a watery solution than if used with the urinary fluid. Furthermore, the delicacy of a glucose test is not the same in all urines, being dependent on quality and quantity of the other urinary constituents. Sensitiveness of a method for the detection of glucose in the urine is by no means identical with its accuracy and reliability. Thus, Trommer's test, for instance, is an exceedingly delicate one, if skilfully applied to certain urines; in the great majority of instances, however, its trustworthiness can not be relied upon for amounts of dextrose less than 0.5 per cent. The same may be said of the other testing methods in general usage. Böttger's or Johnson's picric acid or the fermentation tests are equally delicate under favorable conditions, but, according to my experience, their employment should be restricted to urines containing 0.5 per cent. and more of grape-sugar.

By the application of tests most generally used, pathologic quantities of urinary glucose may be overlooked altogether, or grape-sugar may be confounded with a number of other urinary constituents. Especially is this the case where the other concomitant manifestations are equally ill-pronounced. I have prepared the following list to show the limit of sensitiveness and that of reliability of the different tests:

Tests for Dextrose in the Urine.	Limit of Sensitiveness. Percentage.	Limit of Reliability. Percentage.
BISMUTH TESTS.		
Böttger's	0.1	0.5
Nylander's	0.1	0.3
Brücke's	0.2	0.4
Maschke's	0.2	0.4
COPPER TESTS.		
Trommer's	0.1	0.5
Salkowski's	0.5	0.5
Seegen's (filtration of urine through animal charcoal)	0.01	0.05
Fehling's	0.3	0.3
Worm-Mueller's	0.25	0.3
Haines'	0.2	0.3
Elliott's	0.2	0.3
Pavy's	0.2	0.3
Phenylhydrazin test	0.03	0.05
Moore-Heller's	0.5	0.75
Penzoldt-Rubner's (ammonia-lead acetate)	0.1	0.2
Methylene-blue test	0.04	0.3
Picric-acid test	0.1	0.5
Sodium sulpho-indigotin	0.1	0.5
Hoppe-Seyler's (Nitrophenylpropiolic acid)	0.5	0.75
Penzoldt's (Paradiazobenzolsulphonic acid)	0.1	0.3
Furfurol tests	0.02	?
Horsley-Pratesi's (caustic potash, potassic silicate, potassic bichromate)	0.4	0.75
Fermentation test	0.1	0.5
Polarization	0.01 with best instrument.	1.0 and over by instruments in gener'l use.

In the following I have recounted those disturbing factors which impair the value and mar the lucidness of the different processes commonly employed for the detection of dextrose in the urine:

THE BISMUTH TESTS.

1. Böttger's Process.—This test depends on the reduction of bismuth subnitrate in an alkaline fluid to black metallic bismuth in the presence of sugar.

Disturbing factors and sources of error.—Excessive amounts of pigment, glycuronic acid, mucin and other urinary constituents containing sulphur by the production of bismuth sulphid, which in appearance is similar to bismuth reduced by sugar. (If but traces of sulphur are present, a reddish-brown sediment is produced.) The grayish tint often imparted to the bismuthic salt is by no means indicative of the occurrence of minute amounts of urinary dextrose.

Prevention.—The coloring matter should be separated by filtration through animal charcoal. Most proteid substances are removed by boiling of the acid urine, by acidifying and boiling of neutral or alkaline urine. The coagulate is allowed to settle and the test is performed with the clear urine.

2. Brücke's Method.—The separation of albumin—a possible source of error—Brücke accomplished by the aid of Fron's reagent, an acidulated solution of bismuth—potassium iodid—[5] which, by supplying bismuth oxid, serves at the same time as a detector of urinary glucose. A precipitate of bismuth-iodid is produced in the diluted solution. This sedimentation would, consequently, also occur on the addition of the reagent to the unacidulated urine. As, however, an excess of acid would redissolve the albumin-precipitate called forth

---

[4] Detection of the alkaptonic acids: 1. Reagent—Chlorid of iron. Chlorid of iron added to a solution of homogentisinic acid produces a transitory blue discoloration; added to a solution of uroleucinic acid, the ensuing discoloration is green. 2. Millon's reagent—In unheated alkaptonic acid solutions, Millon's reagent slowly produces a yellow precipitate, gradually turning to orange; the color of the precipitate, on being heated, readily changes to light terra-cotta red. Other tests for the presence of these acids or the methods for their preparation are too complicated for execution by practitioners of medicine. The darker color, when exposed to the air, the negative results obtained with the bismuth, the picric acid and the fermentation tests, the optic inactivity and the heretofore-mentioned tests, suffice for the recognition of alkaptonuria and for its discrimination from glycosuria. However, the definite identification of the acids is possible only by their preparation from the urine.

[5] Preparation of reagent: One and one-half grams freshly-precipitated bismuth subnitrate is heated with 20 grams distilled water to the boiling-point: 7 grams potassium iodid are afterward dissolved in the mixture, which then assumes a red coloration. The whole is finely acidulated with 1.5 **grams** hydrogen chlorid.

by the bismuth, it is essential to ascertain what quantity of hydrogen chlorid has to be added.

The following process is, therefore, recommended: Two test-tubes are filled to the same height, the one with water and the other with the urine to be examined. Sufficient hydrogen chlorid is added to the water contained in the one tube so that a drop of the reagent does no longer produce turbidity. In this manner the amount of HCl necessary to keep the bismuth-iodid in a known volume of the reagent still in solution, is learned. The urine is then acidulated with the quantity thus ascertained, following this the reagent is added, and when precipitation seems complete the whole is filtered. To the filtrate, which should show no turbidity, on the addition of HCl or the reagent, an excess of potassium or sodium hydroxid is added and the mixture treated as in Böttger's test. Bismuth-potassium iodid produces also precipitation of the albumoses (pepton), which does not take place when the common process of albumin coagulation is employed.

Disturbing factors and sources of error.—Glycuronic acid ($C_6H_{10}O_7$) and glycuronic anhydrid ($C_6H_8O_6$), in my experience, invariably impaired the end reaction. An excess of certain pigmentary bodies, especially uro-erythrin, produce a grayish to black deposit of earthy phosphates in urine, rendered alkaline by potassium or sodium hydroxid.

Prevention.—Glycuron and glycuronic acid and its combinations can not be readily separated by means at the command of the medical practitioner. All he can do is to resort to a number of control tests. The coloring matters may be partially eliminated by above-mentioned methods.

3. Maschke's Method.—In this process a solution of sodium tungstate in acetic acid[6] is employed for the separation of the protein substances in the following manner: The addition of the reagent to one-fourth or one-third volume of the urine in a test-tube, causes precipitation of the albuminous material. The urine is then filtered and again treated with some drops of the reagent. If no new precipitate appears in the filtrate, half the latter's volume of concentrated sodium hydroxid and a small amount of bismuth subnitrate—about 0.05 gram—are added and well shaken together. In case the bismuthic salt undergoes a brownish or blackish discoloration before the mixture is subjected to heat, then sulphur combined as hydrogen sulphid is contained in the urine. The removal of the latter is accomplished by agitating a new sample of the urine with acetic acid and bismuth nitrate, the filtrate being afterward treated with sodium tungstate as above. Glucose is only then present when on the application of heat immediate blackening of the bismuthic salt ensues. A brownish hue of the bismuth oxid appearing on heating, or a black discoloration of the precipitate on boiling, for a more protracted period, indicates the occurrence of normal amounts of sugar.

Disturbing factors and sources of error.—Urinary pigments, glycuronic anhydrid, glycuronic acid and its combinations, hydrogen sulphid. Almost every normal urine blackens bismuth oxid when the amount of potassium or sodium hydroxid utilized is far in excess. The reducing substance, however, is not sugar.

4. Nylander's Test.—Almén's[7] solution is the reagent employed in this method. One part of the reagent is added to ten parts of the suspected urine. On boiling for from two to five minutes the white precipitate which is produced by the addition of the test solution to the urine, gradually assumes a more pronounced discoloration, turning finally black in the presence of dextrose. A very small percentage of sugar produces a brown hue of the precipitate; a dirty yellow or a grayish discoloration is of no significance as to the presence of dextrose. A secondary blackening of the precipitate, which may take place when the urine mixture in the test-tube is cooled off, does not evince the occurrence of abnormal quantities of grape sugar. Uric acid and creatinin do not reduce the bismuth salt. Pure peptone does also not influence the reaction. The test boils over easily; this may be prevented by putting the test-tube into boiling water.[8]

Disturbing factors and sources of error.—Pigmentary bodies, principally uro-erythrin, hematoporphyrin, indoxyl-glycuronic acid and other glycuronic-acid compounds, ammonium carbonate in decomposing urines, hydrogen sulphid, mucin, albumin and other urinary constituents into whose composition sulphur enters. If the reagent is added to a 0.6 per cent. albumin solution, a red precipitate will be produced; in urine containing 1 to 2 per cent. of albumin the ensuing precipitate is black, and in appearance easily mistaken with the reduced bismuth salt. The reaction is yet a fair one if 0.2 per cent. albumin occur together with 0.1 per cent. sugar; it is but faint if 0.35 per cent. albumin occurs simultaneously with the same quantity of sugar; if the reaction will not take place, 0.45 per cent. albumin is contained in a 0.1 per cent. sugar solution. Saccharin is among the substances preventing the reduction. Reduction of bismuth oxid has been noticed after the administration of a number of drugs, as antipyrin, acetanilid, arsenic, salicylic acid or salicylates, quinin, sulphur, mercurials, salts of iodin, turpentin, kairin, rheum, senna, santonin, tannic acid, chloral hydrate, tincture of eucalyptus, salol, benzol, sulfonal, trional, sodium benzoate, large doses of creosote (Stern), podophyllotoxin (Stern). There is little doubt, in my opinion, that the administration of some of these drugs is followed by an increased output of urinary pigmentary substances to which the reducing qualities have to be ascribed. In other instances, as with rheum and senna, the reducing power seems to lodge with the newly-ingested chrysophanic acid ($C_{15}H_{10}O_4$).

Prevention.—Separation of the coloring matters, removal of the hydrogen sulphid by agitation with lead oxid, elimination of proteids. Specimen of urine should be voided in a period during which no medicinal agents were administered.

THE COPPER TESTS.

The various copper tests so extensively employed in clinical work depend upon the power of dextrose to reduce cupric oxid to a lower degree of oxidation in strongly alkaline solutions.

Trommer's Test.—The filtered urine is rendered alkaline by the addition of one-third its bulk of sodium and potassium hydrate. Then, drop by drop, a 5 to 10 per cent. solution of copper sulphate is added under constant agitation until the blue precipitate of cupric hydroxid—$Cu(OH)_2$—which appeared upon the addition of the first drop of the copper sulphate solution, does not dissolve any longer. After this the mixture is slowly heated, but never to the boiling-point. If sugar is present, the dark-blue color disappears, and a yellow or red precipitate of cuprous oxid (CU_2O) is rapidly produced while in the course of heating.

---

[6] Preparation of reagent: Crystalized sodium tungstate, 30 parts; acetic acid—30 per cent.—75 parts; distilled water, 120 parts.

[7] Preparation of reagent: Potassium and sodium tartrate, 4 grams, and basic bismuth nitrate, 2 grams, are, under heat, dissolved in 100 grams of an 8 per cent. solution of sodium hydrate. When cooled the yellow bismuth oxid is filtered off and the solution, which does not deteriorate for a long time, is kept in a dark bottle.

[8] The reduction or pseudo-reduction of the bismuth salt may be frequently due to substances other than dextrose. The chief value of this test, however, lies in its negative result, for the non-reduction of the bismuth positively excludes the presence of glucose in abnormal quantities.

Notes.—If either sugar, albumin, ammonia, tartaric acid or glycerine is contained in the urine to be examined, the precipitate of cupric hydroxid is redissolved and the fluid turns dark blue. If, on the other hand, the precipitate does not dissolve at all when the test-tube is strongly shaken, it may be concluded that abnormal quantities of dextrose do not occur in the urine. Should the blue mixture on being heated change its color to yellow without the production of a cuprous oxid precipitate, or should the latter appear only while the mixture is *boiling,* or when it has *cooled off,* it is dubious whether the reaction was caused by grape-sugar or not. It is solely the rapidly-occurring reduction of the copper salt taking place before the boiling-point is reached which is of significance as to the presence of glucose. An eventual deposit, on cooling, consists of flocculent earthy phosphates. Prolonged boiling may call forth a black discoloration of the mixture by the separation of copper oxid and metallic copper. As normal urine also possesses decolorizing qualities, and as the amount of urine necessary to perform Trommer's test is a comparatively large one, reduction of the copper salt may readily ensue by the action of urinary constituents other than dextrose.

Disturbing factors and sources of error.—There are two classes of urinary substances which interfere more or less with Trommer's and other copper tests. 1. Such bodies, besides glucose, which cause copper reduction. 2. Such elements, which, when present in increased amounts, will prevent the reduction. To the first category belong uric acid, the urates, creatin, creatinin, hypoxanthin, allantoin, hippuric acid, indican, alkaptonic acids, nucleo-albumin, urinary pigments, glycuronic acid, brenzacatechin, hydrochinone, lactose and other carbohydrates. The urine possesses copper-reducing qualities after administration of alkaloids, arsenic, tannin, gallic acid, pyrogallol, camphor, copaiba, cubebs, chrysophanic acid, salicylic acid and salicylates, oxalic acid, chloral hydrate, acetphenetidin, turpentin, glycerin, sulfonal, thallin and benzoic and carbolic acids. These urinary constituents and drugs, however, call forth but an incomplete reduction, viz.: Discoloration of the fluid without production of precipitate, or formation of precipitate on boiling only or when cooled off. Among the substances which when present in increasing amounts prevent or retard the reduction, we find albumin, parapepton, peptone, salts of ammonia, saccharin. Urine rich in ammonia—after the decomposition of carbamid into ammonia carbonate—may keep the cuprous oxid in solution. Such a urine may become decolorized, but it may retain its transparency on boiling. Albumin prevents the separation of cuprous oxid, but mere traces of albuminous substances do not interfere with the test.

Prevention.—For the purpose of eliminating these disturbing factors a number of suggestions and modifications have been advanced. Dilution of the urine with water has been recommended to neutralize the influences of reducing agents other than glucose. The diluent, however, must not be added in such excessive quantities as to prevent the copper reduction by the grape-sugar itself. Sr. Johnson believes that all reducing substances, with the single exception of dextrose, may be separated from the urine in the form of mercuric oxid combinations. The process recommended is this: To the suspected urine 0.05 its volume of cold saturated solution of sodium acetate and 0.25 its bulk of cold saturated corrosive mercuric chlorid solution are added. Forty-eight hours after, the precipitate containing uric acid and creatinin is filtered off. If by the careful addition of ammonia the excess of mercuric oxid is removed from the filtrate, glucose in normal urine can not be detected any longer. However, if the mercury is separated from the filtrate with aid of hydrosulphuric acid (H_2S) and the latter is removed by boiling, the fluid is said to reduce more perfectly than it did in its original composition.

(To be continued.)

MEASUREMENTS OF CHICAGO SCHOOL CHILDREN.*

(Concluded from p. 623.)

W. S. CHRISTOPHER, M.D.

Professor Pediatrics, Medical Department, University of Illinois;
Professor Diseases of Children, Chicago Policlinic; Chairman
Child Study Committee, Chicago Board of Education.
CHICAGO.

RELATION OF INTELLECTUAL AND PHYSICAL CONDITIONS.

As a result of his examination of 33,500 school children in St. Louis, in 1892, Dr. W. Townsend Porter concluded that there is a physical basis of precocity; that dull children are lighter, and precocious children heavier than the average child; that mediocrity of mind is associated with mediocrity of physique. At the outset of my observations I determined to reinvestigate Porter's proposition, and have to say that such facts as we have been able to collect go to confirm it.

There were met, in the course of these examinations, 503 children, aged 12, who were distributed throughout the grades from the second to the eighth, inclusive. A few were also found in the high schools. The physical peculiarities of these children, in each of the points examined is set forth graphically in the following charts. In these figures the averages of each particular measurement of the children of this age in each grade are taken, in the belief that with the small numbers, averages are closer to the truth than means.

Fig. 29 represents the average height of all of the 12-year-old children in each of the grades. It will be noted that the curve representing these averages rises with striking regularity from the second to the seventh grade. A slight decline is noticed in the eighth grade, probably due to the small number of children found in that grade. The grading of the pupils is upon an intellectual basis, hence the chart shows superior intellectual capacity is associated with superior stature, and inferior intellectual capacity with inferior stature, the age being the same throughout.

Figs. 30 to 33, inclusive are constructed in a manner similar to that employed in drawing Fig. 29, except that each is based on a different physical measurement, as indicated on the figure. In constructing these, the 12-year-old children alone have been charted, for the double reason that a single line is more illustrative, and because children of this age are more widely distributed through the grades. The other ages have been examined sufficiently to show that the laws here illustrated hold good for them. The close correspondence between the curves of height, weight, strength of g [illegible] vi capacity is very striking. The slight va [illegible] ergographic curve should not be consi examination of a larger number of pupils determines whether or not it is accidental.

My observations, therefore, so far as they go, support Porter's conclusion: *that superior mental and physical qualifications are generally associated, and inferior mental and physical qualifications are likewise generally associated.*

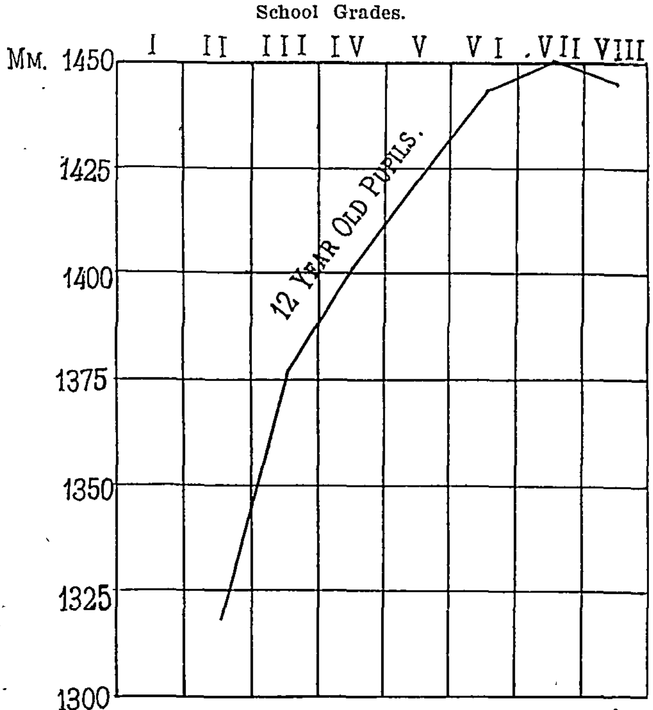

Fig. 29.—Height and School Standing.

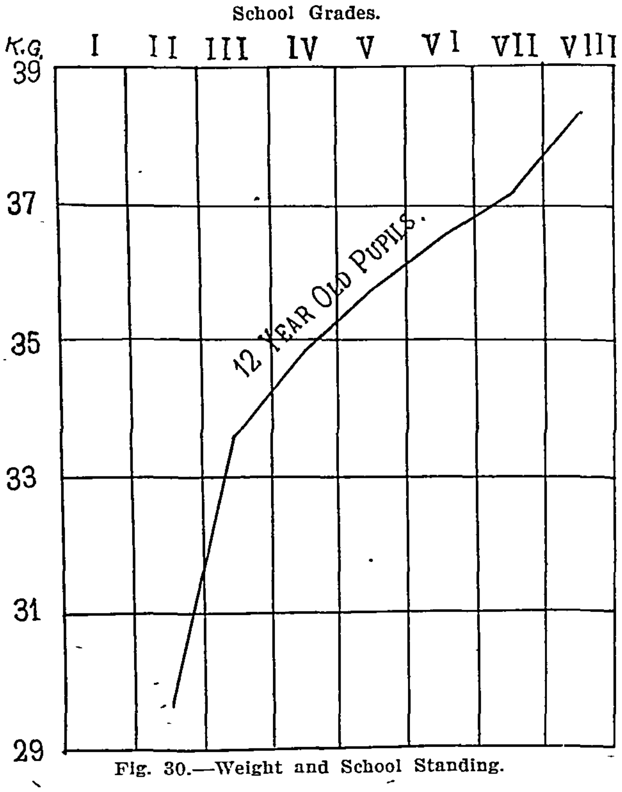

Fig. 30.—Weight and School Standing.

PHYSICAL EXTREMES IN EACH ROOM.

Figs. 34 to 38 illustrate the extreme maximum and minimum measurements met with in each of the twenty-four rooms at the Alcott school. From Fig. 34 it appears that the difference in height between the tallest pupil in the first grade and the shortest pupil in the eighth grade is very slight, being, in fact, only 18 mm., or less than three-quarters of an inch. The greatest range of stature is found in one of the fifth-grade rooms, and amounts to 530 millimeters, or 21 inches. *These facts I have used in the Board of Education as an argument for the use of adjustable desks.* The chart of extremes in weight shown in Fig. 35, as might be expected, is more irregular than that of extremes in height, since obesity and slenderness are nutritional manifestations dependent on several other factors than *those concerned in the determination of stature.*

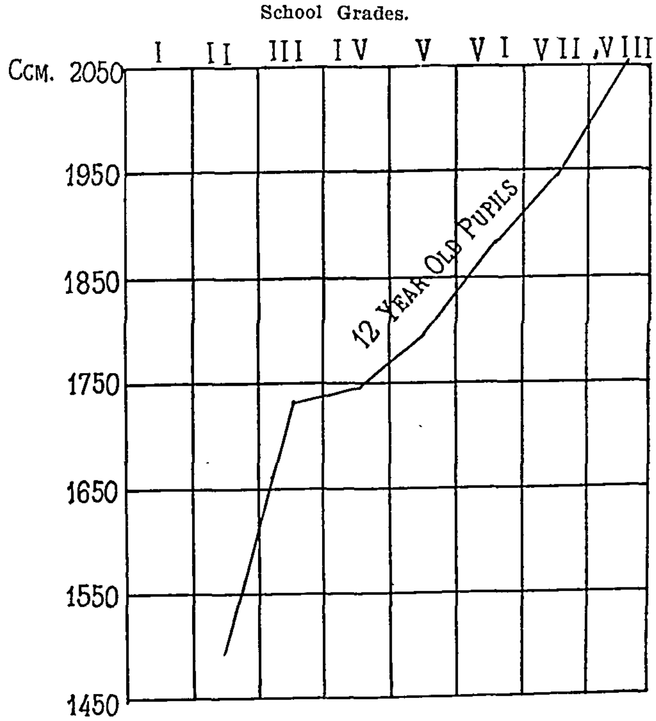

Fig. 31.—Vital Capacity and School Standing.

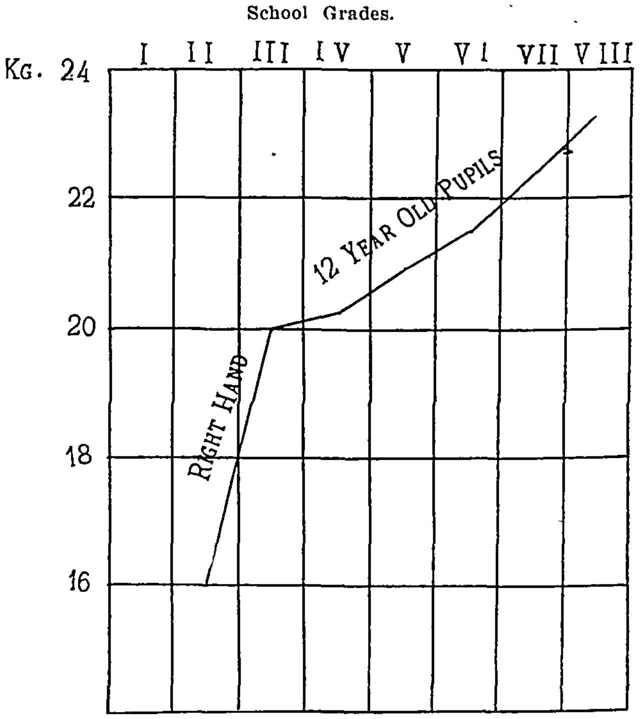

Fig. 32.—Strength of Grip and School Standing.

The extremes of ergographic work shown in Fig. 36 are very instructive. In the first grade the minimum endurance is 28.3 per cent. of the maximum endurance. This percentage continuously decreases until the seventh grade is reached, where the minimum endurance is only 18 per cent. of the maximum, and in the eighth grade it is 18.5 per cent. The actual differences are even more striking than these relative differences. A glance at the chart shows that the minimum endurance is almost the same in each of the grades, while the maximum endurances differ widely from each other. Figs. 37 and 38, giving extremes in strength of grip and in vital capacity, show essentially the same conditions as those found in the other charts of extremes. The most striking fact shown by these charts is the increase in the range of the extremes as we advance through the grades. Even before the causes of this increase in the range of the physical extremes in the upper grades is determined, the fact itself calls for greater elasticity in the work of those grades.

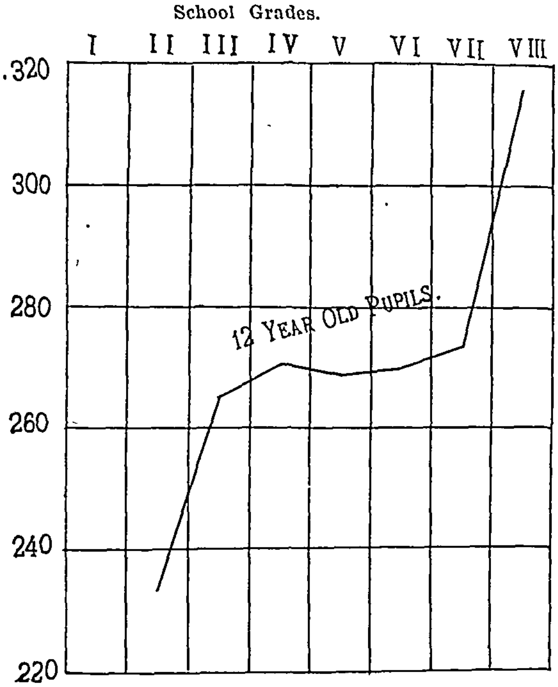

Fig. 33.—Ergograph and School Standing.

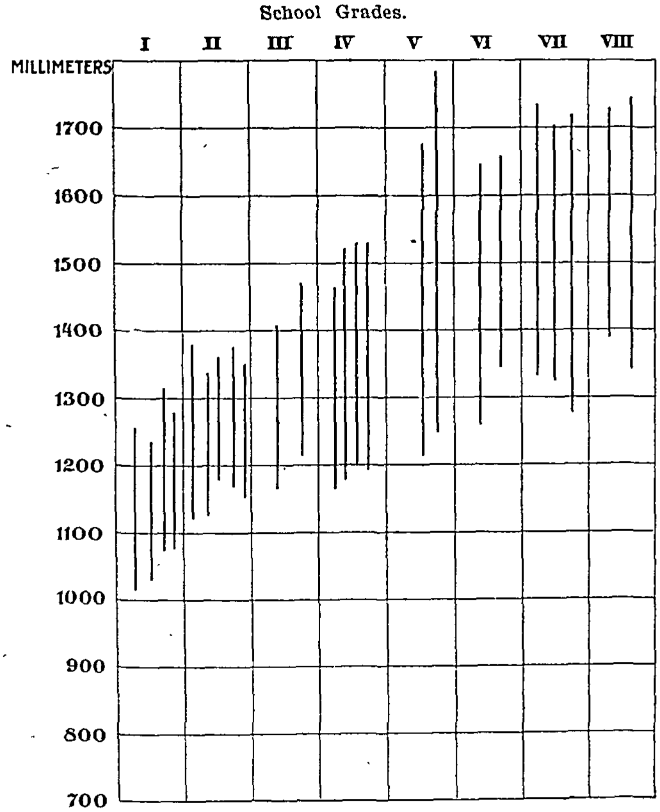

Fig. 34.—Differences in Stature Between the Tallest and the Shortest Pupil in Each Room of the Alcott School.

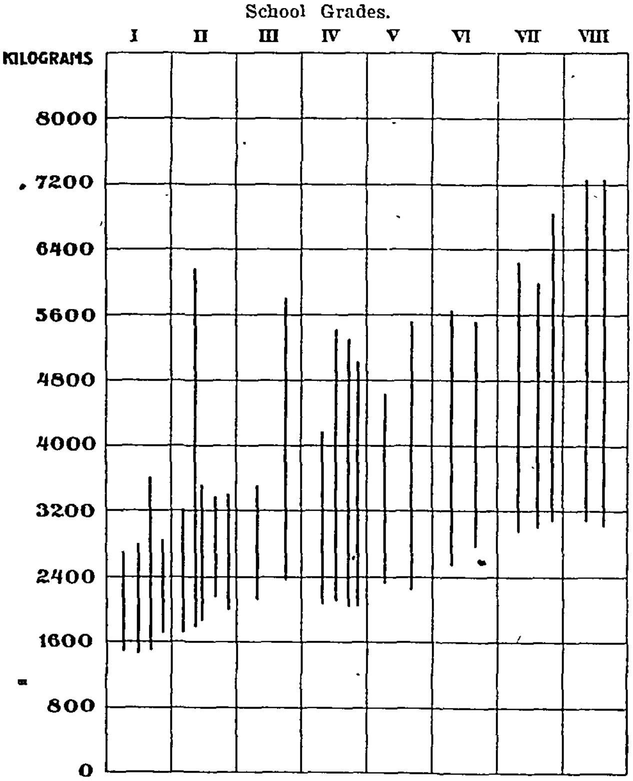

Fig. 35.—Differences in Weight Between the Lightest and Heaviest Pupil of Each Room of the Alcott School.

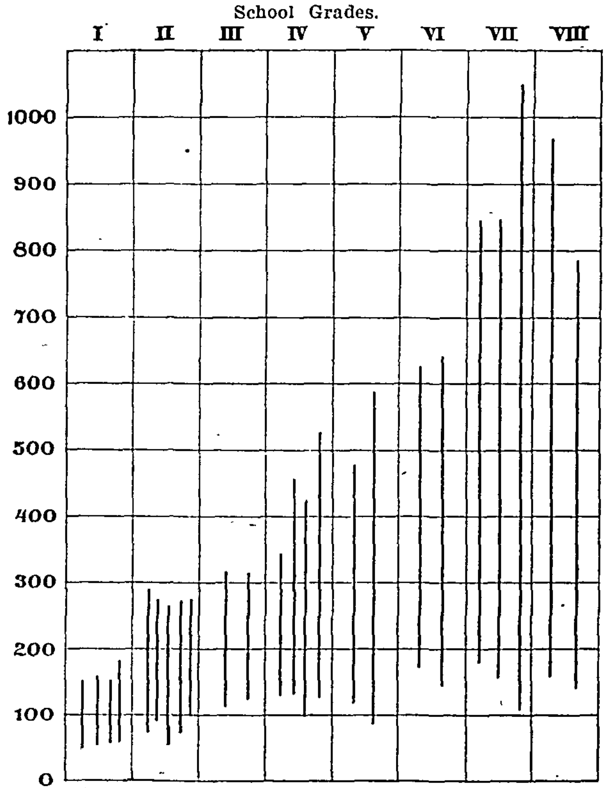

Fig. 36.—Extremes of Work on the Ergograph.

At present the work in physical culture in the schools is done by rooms, and the rooms are graded on an intellectual basis exclusively. This is, on its face, bad for the work in physical culture, but how [illegible] is [illegible] not be known until such facts as furnished by these tables of extremes had been worked out. If physical culture is to accomplish the most possible for the pupils of our

Total tested . . .	4765				

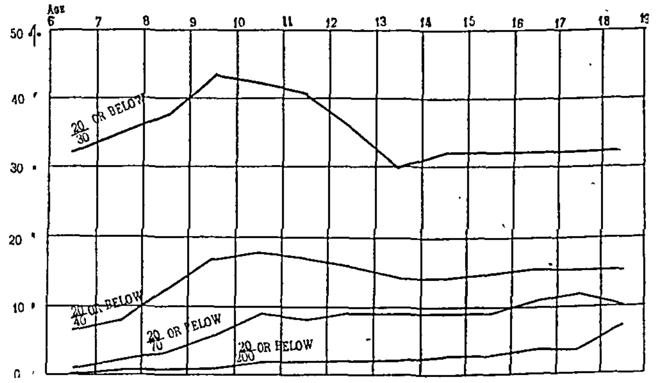

Fig. 40.—School Life and Sight. (Based upon Examination of 4765 Pupils.)

This figure differs somewhat from Fig. 39. It shows that the visual acuity diminishes during the first three years of school life, *instead of only during the first year as indicated by Fig. 39.* The improvement of vision at puberty, however, is still found to hold good.

Figure No. 39 is based upon the examination of about 1600 pupils. Since this chart was made the results of the examinations of the eyes of 4765 pupils in the Chicago Schools have been compiled. These results are shown in the following table, which gives the number of pupils of each age examined, and also the percentages of those in whom the visual acuity in one or both eyes was 20-30 or lower, 20-40 or lower, 20-70 or lower, and 20-200 or lower. The figures of this table are graphically shown in the accompanying Fig. No. 40.

tive vision, a percentage which rises to 42 at 7 years, dropping slightly immediately thereafter, and remaining essentially unchanged until the age of 12, where it is 36 per cent. Then comes a sudden drop to 23 per cent. at 14, with a return at 16 to the previous general standard. This chart certainly negatives the generally accepted idea that continued school life impairs the vision. I have no explanation to offer for the sudden impairment of vision between 6 and 7. The increased acuity of vision at 14, reaching a point of greater acuteness than is found even at 6 years of age, is so closely connected in time with the changes incident to puberty that it does not seem unwise to consider it as one of the conditions belonging to that period of florid growth and development.

BACKWARD CHILDREN.

It is in the study of backward children that the lines of thought of the schoolmaster and childrens' physician come together most intimately. In every large school system there is to be found a considerable number of pupils who are too backward mentally to keep up with their classes, or, indeed, to even drag along, and whose presence in the class rooms with normal children serves only to retard the latter without appreciably benefiting themselves. They are, however, not sufficiently backward to warrant putting them in the state institutions for the feeble-minded. The defects from which these children suffer, and to one or more of which, in each individual child, *is to be traced the cause of its intellectual deficiency*, may be classified as follows:

DEFECTS FOUND IN BACKWARD CHILDREN.

Location.	*Kind.*	*Cause.*
Sensory tracts.	Structural—	Heredity—
Central Nervous System.	Developmental.	Environment.
	Acquired.	Nutrition.
Motor tracts.	Functional—	Infection.
	Developmental.	Climate.
	Acquired.	Dwelling.
		Clothing.
		Physical activities
		Mental activities.
		Discipline.
		Traumatism.

Diagnosis of a backward child consists in:

1. Determining the defects present—sensory, motor, or associative.

2. Determining the kind of defect—structural, functional—developmental, acquired.

3. Determining the causes of these defects—heredity, nutrition, infection, and other environmental factors.

In making such diagnosis it is evident that there is required the services of the practical pedagogue, the psycho-physiologist, and the medical man. So also in the management of the cases the practical knowledge of both educator and physician must be brought to bear. Moreover, they must work in consultation and not at long range. The close relationship between medical and educational work is thus readily seen in the management of the backward child. A moment's consideration will also show that this relationship is equally close in the management of all other children. While the physician and educator are ready to meet and combine their efforts on behalf of the child, it is unfortunate that the moral teacher seems not yet ready to come in to complete the trio.

A large part of modern education is devoted to processes of developing the senses, and the motor functions. From the natural limitations of his methods of work, however, the schoolmaster is often unable to have his subject in the best condition to profit by his methods. He can not fit spectacles, he can not remove adenoids, he can not supply deficiencies in food, whether quantitative or qualitative, he can not remove toxic influences. Some of these things the physician can do. These remarks on the subject of backward children, apparently somewhat remote from the subject-matter of this paper, have their reason in the results of an examination of twenty backward children in one of the Chicago schools last spring. These children were gathered together into a so-called "ungraded" room. There were sixteen boys and four girls. The average age of the boys was 11 years, 5 months, and 10 days; that of the girls was 10 years, 4 months, and 21 days. A number of developmental defects was noted among these pupils, which would suggest imperfect formation of the brain. Two are marked as being microcephalic, their heads being below normal in size. Seven of the twenty are recorded as having cranial asymmetry; eight as having asymmetrical faces. Six are noted as having peculiarly formed ears, and nine as having narrow, high, or imperfectly formed palates. Five of the pupils had decided eye defects, the visual acuity being twenty-thirtieths or lower, while thirteen had hearing so defective in one or both ears as to place them at a disadvantage in school work. That is, 60 per cent. reached a subnormal point in hearing, to which only 24 per cent. of the Alcott school pupils of the same age fell. Malnutrition was shown by marked anemia in two of the pupils. Want of muscular tonicity was noted in seven. The nervous ergographic tracings with most of these children and the small amount of work done on the ergograph by them would indicate the same condition.

The averages made by these pupils was lower in every particular than the averages made by the Alcott school pupils of the same age, as will appear from the following table:

Comparison of the averages made in the tests by the pupils of the ungraded room with the Alcott School averages, reduced to the same age.

	Net Height. mm.	Height Sitting. mm.	Weight. kg.	Work on Ergograph. cm. kg.	Combined Strength of Hands. kg.	Vital Capacity. c.c.
Girls of ungraded room	1,274	692	27,325	100	23.8	1,375
Alcott School normals for the same age	1,323	704	29,033	180	24.4	1,444
Boys of ungraded room	1,362	724	30,880	206	32.4	1,762
Averages for same age at Alcott School.	1,378	727	31,888	261	34.6	1,763

Signs of Pancreatic Affection.—Scherschewsky has noticed that hypertrophy of the pancreas consecutive to that of the spleen compresses the abdominal aorta and causes a murmur below. Pain in the stomach region immediately after eating is another symptom of a pancreatic affection, and also reflex pains from compression of the nerve roots, such as the girdle feeling and cramps at the neck of the bladder. There is also a palpable pulsation in the stomach region, accompanied by distress and palpitation. His article is published in full in *Vratch*, No. 38.

Gutzeit Test for Arsenic in Urine.—One c.c. of urine is mixed with 4 c.c. sulphuric or hydrochloric acid, a bit of sugar added, the tube plugged with cotton and covered with a piece of filtering paper moistened with silver nitrate. It is then set aside in a dark place. If there is arsenic in the urine a yellow spot will develop on the filtering paper, its size and intensity indicating the proportion of arsenic in the urine. Blumenthal, of the Moscow Institute for Bacteriology, endorses this test as absolutely certain and accurate.—*Derm. Cbl.*, August 1.

Army Surgeons Required.—The Surgeon-General of the Army announces that 100 additional medical officers—acting-assistant surgeons—are required for duty in the Philippines and China. Only experienced graduates of reputable medical colleges, under forty years of age will be accepted.

FINSEN'S PHOTOTHERAPY.

Finsen's investigations of the therapeutic and other properties of light have been followed with a great deal of interest. In Copenhagen a public institute, founded by public and private means, has been in operation for some time and a great deal of work has been done, especially in the treatment of lupus and other cutaneous diseases, with concentrated light. Patients have been attracted from various European countries and from America; similar institutes are being or have been established in London, Moscow, and elsewhere. Medical men have visited Finsen's institute in Copenhagen, and the reports are unanimous in their praise of the well-known Danish open-handed hospitality, and of the true scientific spirit of Finsen and his assistants. The result of this treatment of lupus vulgaris is certainly satisfactory. Inasmuch as this is a new and striking departure in therapy, surely destined to grow in importance and usefulness, it may be as well to point out briefly some of the steps in its development.

In 1893 Finsen proposed a new treatment of variola. The patients were placed in a room from which the chemical or actinic rays of the solar spectrum were excluded by the use of red glass or red curtains. When patients with smallpox are so treated from an early period of the disease, the vesicles do not become pustules, suppurative fever is absent, and there is but little or no variolous pitting. At first this announcement was received with more or less incredulity, but it has been confirmed from various sources, and there is not the slightest doubt that the exclusion of the actinic rays greatly mollifies the course of smallpox.[1] Arrangements to carry out this treatment should be made in all our smallpox hospitals. Let it be remembered, however, that it must be instituted early in the attack, and before the pustular stage.

How is this action explained? The actinic rays all come from the blue and violet end of the spectrum; their action is largely chemical and they produce but little heat; in contradistinction from the rays from the other end of the spectrum—the red rays—whose action is principally heat-producing. All are familiar with the effects of solar and other forms of light on the skin when unduly exposed. The changes vary from increased pigmentation to violent and complex forms of dermatitis. Finsen and others have demonstrated that it is the actinic, and not the caloric, rays that cause these changes in the skin. This being the case, it is only natural to look for still greater morbific action on the part of the actinic rays on skin already diseased, as in smallpox; and the beneficial effect of excluding the ultraviolet rays shows this to be the fact. Consequently, the mechanism of the action on the skin of actinic rays, their influence on the chromatophorous cells in lower animals, and other interesting physiologic facts and phenomena need not be discussed at this time. We see that this method of treating smallpox, at first somewhat strange and incomprehensible, has a fairly solid scientific basis. So far, exclusion of the actinic rays in treatment of variola has not been found to have any general injurious effects on the patients.

Finsen's studies of light as an agent of excitability[2] have shown that here again it concerns principally the action of the actinic rays; these rays determine in a very pronounced manner certain movements in lower animals. These rays are therefore quite certainly carriers of energy of great biologic importance. In addition to heat and to light, the rays of light also bring chemical forces which have not received much special attention in medicine. These forces certainly merit careful study. Singularly enough, Finsen, who called attention to their noxious effects—and the treatment of smallpox by exclusion of the actinic rays resulted—is also the one to introduce the treatment of other diseases by exposure to actinic rays. Sun-baths are not new; they have been employed in various forms since antiquity. Even baths in blue light have been used. Finsen[3] notes the work of an American by the name of General Pleasanton, who utilized blue light in diverse ways for its effects on growing plants, and also in the treatment of disease. Pleasanton published a book, printed on blue paper, entitled: "The Influence of the Blue Ray of the Sunlight, and of the Blue Colour of the Sky, in Developing Animal and Vegetable Life, in Arresting Disease, and in Restoring Health in Acute and Chronic Disorders to Human and Domestic Animals."[4] Here the remarkable chemical qualities of the blue rays are magnified into a panacea.

Finsen's treatment of lupus vulgaris is based on the bactericidal power of light. Theoretically, light should have good effect on superficial cutaneous processes of bacterial origin; but the bactericidal action of light is slow, and on that account he uses mirrors and lenses to concentrate the rays at the same time as the ultra-red, the red, the orange, and the yellow rays are excluded, because when concentrated these rays would cause a burning or necrosis of the tissues. Thus the most actively bactericidal rays, namely, the blue, are allowed to play on the diseased tisues for a considerable time each day. While the sun is the best source of light, it is not always available, and in that case electric light is used. By experience it was found that concentrated light kills bacteria many times more rapidly than diffuse light. Without going into practical details, suffice it to say, that a large number of cases of lupus vulgaris have been cured by phototherapy at Finsen's institute after a prolonged treatment, and that the amount of scarring is only moderate. The method is beginning to be used in other cities and it is probable that its use will be extended to other diseases.

PERNICIOUS ANEMIA.

Despite the time and industry that have been expended in the study of so-called pernicious anemia, the true character and the intimate nature of the disease yet await elucidation. The most plausible explanation as yet propounded is that the disorder is a toxic process, although it has not been shown that it is dependent upon any known substance introduced from without, and it is not unreasonable to suspect that it may result from some obscure derangement in metabolic equilibrium—an autointoxication—and therefore of cellular origin. In no other way, scarcely, would it be possible to account for the variations in the course of the disease, the constancy of its symptoms, and generally its progress to a fatal termination. If this hypothesis prove to be correct, the interesting and important question will then arise as to whether we can hope to obtain a cellular or other product capable of neutralizing the evil effects produced, or of replacing the lost activity. Meanwhile, any addition to our clinical and pathological knowledge with relation to the disease must be cordially welcomed. In a communication presented at the recent meeting of the Association of American Physicians, Cabot[1] reports the results of an analysis of 110 cases of pernicious anemia in which the diagnosis was based in 19 on evidence yielded by autopsy—in addition to clinical investigation—in 60 on the presence of typical symptoms, signs, blood-examination and course, with a fatal termination—without autopsy—in 31 on the same phenomena except a fatal termination. Of these cases, 57 occurred in males and 53 in females.

The majority of patients came under observation after the 40th year, and only 28 earlier. No typical case was observed in a patient under 9 years of age; 63 were between 40 and 60, 19 over 60, 4 over 70, the oldest being 79. In 4 cases the symptoms set in immediately after parturition or during a previous pregnancy, and in 14 at the time when the menopause was expected. No definite relation with syphilis or internal parasites was noted in any case. A history of tertian malarial fever was given in 4 cases. Hemorrhage was a symptom in 37 per cent. of cases. Two cases were complicated by diffuse nephritis. No relation to carcinoma was noted in any case. Psychic factors were prominent in 3. The earliest and the most common symptom was muscular weakness. Next in frequency was pallor, in the majority with a yellow cast. Then, in the order of frequency followed dyspnea and gastric symptoms—nausea or vomiting. In more than half of the cases the gastric symptoms occurred paroxysmally, with intervening periods with relatively good digestion. Lack of appetite was complained of in not more than two-thirds of the cases. Swelling of the lower extremities was fairly constant, although relatively late. Palpitation was less complained of than dyspnea. In most cases functional heart-murmurs were present. In 17 there was evidence of mitral regurgitation and in 6 enlargement of the heart. The condition of the bowels was abnormal in the majority of cases. In 43 there was diarrhea, in 32 constipation. Vertigo was present in about one-half of the cases, headache in 34; ringing in the ears in 30, and signs and symptoms suggestive of changes in the spinal cord in 31. Difficulty of vision was mentioned in 20 cases. Retinal hemorrhage was found in 15 of 36 cases examined. Enlargement of the liver was present in 30 cases, and of the spleen in 13 cases. Evidence of emaciation existed in about one-half; elevation of temperature, in about two-thirds; albuminuria in 23, with tube-casts in 21. The urine was usually pale in color or normal. Only twice was it dark. The importance of making repeated examinations of the blood in doubtful cases is emphasized on account of the variability, from day to day, and a description of the blood conditions during remissions is given. When the red blood-corpuscles begin to increase in number, the color-index may remain high or become even still higher. As a rule, in the remissions the color-index is relatively low. Under the former conditions there may also be slight leucocytosis, made up largely from an increase in the polymorphonuclear neutrophiles and probably due to increased activity of the bone-marrow. At the same time, the percentage of lymphocytes diminishes, and the myelocytes disappear. The number of megaloblasts steadily decreases, and they are for a time replaced by normoblasts, although these also soon disappear. The size of the individual red cell is greater at some times than at others, but soon it becomes normal or subnormal. Abnormal staining reactions and oval forms disappear. The number of red cells falls to about the level of three million.

The following features are considered distinctive in the diagnosis of pernicious anemia: 1, a slow, insidious onset, without recognizable cause; 2, remarkable freedom from pain; 3, striking absence of emaciation—in most cases; 4, the frequent presence of symptoms suggestive of disease of the spinal cord; 5, paroxysmal attacks of diarrhea and vomiting occurring without any obvious relation to diet or to treatment, preceded and followed by periods in which digestion and absorption are performed without apparent difficulty; 6, the tendency to marked spontaneous imp[illegible] in [illegible] the symptoms, followed by rapid [illegible]

---

[1] American Journal Med. Sciences, August, 1900, p. 139.

7, a reduction in the red corpuscles to a point below two million per cmm., without a corresponding reduction in the hemoglobin; a reduction in the number of leucocytes, and especially in the number of polymorphonuclear neutrophiles; the presence of large numbers of over-sized, well-stained red corpuscles, some of them containing nuclei—megaloblasts—together with a tendency to abnormal staining reactions, and to an oval shape in the red corpuscles. On the other hand, the following features are considered distinctive of the secondary or symptomatic anemia; 1, the presence of a well-recognized cause; 2, the steady progress of the symptoms, especially in cases of malignant disease; if gastrointestinal symptoms are present, they seldom improve spontaneously; 3, emaciation; 4, a relatively low percentage of hemoglobin, while the number of leucocytes, especially the polymorphonuclear neutrophiles, is likely to be increased, though by no means invariably. The size of the individual red cells is usually normal or diminished, and their centers are strikingly pale. Over-sized red corpuscles may be present, and may occasionally contain nuclei, but, as a rule, they are greatly in the minority, and such nucleated red corpuscles as are present are chiefly of the normoblastic type. The tendency to abnormal staining-reactions and to an oval shape in the red corpuscles is usually much less marked than in cases of pernicious anemia. Latent gastric carcinoma is practically the only disease likely to be confounded with pernicious anemia.

Of 90 of the cases, only 20 were progressive in course. In 70 there were one or more remissions, with great improvement, disappearance of the symptoms for the most part, while the color-index and the blood-count became nearly or quite normal. Emphasis is placed on the fact that pernicious anemia is not a progressive disease, but is attended with successive waves or paroxysms of alternate remission and exacerbation, for the most part without reference to treatment. Of 70 cases observed from beginning to end, the majority lasted less than two years, 12 more than three, 2 more than four, and the longest, five years. The number of relapses varied from 2 to 5 or 6. Out of the whole series, there was no case of genuine recovery. In treatment, Fowler's solution of arsenic, bone-marrow, and inhalations of oxygen were used, as well as laxatives or purgatives, but no good results are attributable to them.

PRIMARILY MULTIPLE PROLIFERATIONS OF BONE-MARROW—MYELOMA.

The bone-marrow is a complex structure harboring many different kinds of cells and performing a corresponding number of varying and but little understood functions. On account of its hidden and well-protected situation, the bone-marrow generally escapes observation and hence the knowledge of its pathologic changes is not as widely spread as of the changes of more accessible tissues. In addition to the changes that occur in pernicious anemia and other blood diseases, primary and secondary, and to inflammatory and suppurative processes, bone-marrow may be the seat of tumors of various kinds, both secondary as well as primary; but the clinical and anatomical relations of the primary forms are probably not yet fully worked out. In addition to myelogenous sarcoma, with its interesting giant cells, and to endothelioma, there occurs a primarily multiple, primary tumor growth of the marrow of certain bones, especially the vertebræ, the ribs, and the skull-cap, that is, the red marrow of adults. So far, this tumor has not been found to develop from the normal yellow marrow of the long bones. The new tissue resembles red marrow in its general appearances, and it gradually replaces the bony tissue, causing more or less diffuse, as well as nodular enlargements of the affected bones; occasionally it breaks through the periosteum and forms small infiltrations outside of the bones, but on the whole the tumor tissue is closely confined to the marrow, from which it can not be distinguished. The ribs not uncommonly undergo spontaneous fractures, and sharp curvatures may develop in the spine, as in a case recently described by Winkler,[1] which developed after a fall of about six feet. Similar curvatures also develop in the sternum, which may become greatly thickened and swollen. In nearly all cases—Winkler insists that so far, in every case—the external organs have been free from metastases, the growth confining itself strictly to the bones. In the case described by Herrick,[2] however, there is a record of double ovarian tumors of the same structure as the infiltrations of the marrow. This case seems to have been an extremely well-marked example, and there is no apparent reason why metastases may not occur, especially in the latter stages of such luxuriant proliferations of the marrow as there described. The lymph-glands and the spleen are not enlarged. There develops a pronounced anemia, the exact character of which has not been studied sufficiently. And in the urine Bence-Jones' albumose has been observed by Kahler and Pick, Fitz, and others.

The microscopical structure of the new tissue is homologous with red marrow, in so far as the tissue consists almost wholly of round cells of the same size and with rather large nuclei; giant cells are not present, except for occasional osteoclasts in the Howship's lacunæ of the disappearing bone trabeculæ; fine fibrillæ and blood-vessels occur among the tumor cells. Wright[3] shows that a large number of the cells give the staining reactions of the plasma cells, being apparently derived from similar cells present in normal marrow.

It is clear that this tumor is peculiar and has a definite physiognomy. It should not be confounded with pseudoleukemia, lymphosarcoma, periosteal and myeloid sarcoma, or carcinoma of bones. From the homology of its structure with red marrow, v. Rustitzky, who described the first case, named the tumor myeloma, and this is the name the disease is destined to bear, although cases have been recorded under other and more misleading designations.

AN ADAMLESS EDEN.

The *Denver Republican* in a recent issue—August 26—analyzes some curious statistics of the population of that section, and comes to the conclusion that at present rates of progress Colorado will have before long only a feminine population. It says, with perhaps an excusable exaggeration considering the actual formidable figures it presents, that "though many more females than males are born in this state, there are two deaths of males to every death of a female." Hence, it foresees the day when Colorado will be an Adamless Eden, or very nearly one, for it is not expected that men will or can be kept out, in spite of the deadly effects of the climate or whatever else is thus affecting that region. The figures from the State Board of Health, which it quotes, show a range of from 30 to 70 per cent. excess of mortality of males over females each month of the present year, a ratio that would, if continued, soon exhaust the resident male population. How this comes about is hard to see, as no specially masculine pestilence is reported, but, of course, figures can not lie. The only suggestion that readily occurs is the proximity of Utah, but that state does not appear to be similarly suffering. The problem is left for solution to the local vital statisticians.

THE CENSUS AND MORTALITY STATISTICS.

Considering the fact that the increase of urban population is one of the tendencies of the time that troubles well-wishers of the race, and its outcome is looked on with some fearful questioning by economists, the insane ambitions of municipalities to exceed each other in population has a rather peculiar aspect. The revelations of the census have been a serious disappointment to many, and they already affect to some extent the health statistics of several municipalities, which suffer somewhat in the increase of their death-rate corresponding to the decrease of population from their estimate. It is probable that when the figures are fully in, some changes in this direction will be found to be quite general, though perhaps not extensive enough to materially affect the records. We notice a tendency to disregard the census figures in some quarters, the health officials claiming that they are in error. It seems to us that even if there is a possibility that such is the case it would still be better to follow them as the best accredited official records. The increase of death-rate would probably not be large in any case, and the data would be free from the suspicion that they had been affected or sophisticated through local feeling. A slightly too unfavorable record in this respect is better than the opposite; it has the advantage of being on the safe side and in such, as in many other matters, there is a certain power in understatement.

PATHOLOGIC ASEPSIS?

According to a German physician who recently spent some months in the Arctic region, the atmospheric conditions there have a very decided influence on germ infection and the behavior of wounds. When the air was clear and dry, putrefaction was arrested, and open wounds, though subject to constant irritation, did not inflame, but did not heal, nor show a tendency to form a scab. In damp, cloudy weather, on the other hand, mold and decomposition appeared and the slightest wounds inflamed and festered at once, though healing progressed rapidly after evacuation of the pus. A somewhat similar slowness of healing and irregular behavior of wounds have been noticed also by other Arctic travelers, and have been attributed by some to a scorbutic tendency thus manifesting itself. The fact, however, in the light of modern theories, suggests the notion that the healing powers of the system require the stimulus of germs and that an absolutely aseptic wound would go neglected and uncured. Even the most rudimentary form of inflammation may require a little sepsis for its start, and the old notion of "laudable pus" have at least a minute basis in fact. The idea is somewhat comforting on the whole, since it implies that absolute freedom from germs, so difficult to be obtained, may not be such a desideratum after all. Perhaps, when we have done our best we can console ourselves that we have left the little leaven of salutary irritation to stir up the organic processes of cure, and that this is as essential as the exclusion of the excess that would carry the process over the line of what we may call the normal pathology of reparative incipient inflammation.

SEA-WATER AND THE CELL.

A French physiologist, M. René Quinton, in a paper read before the last International Medical Congress maintains that all animal life, having first originated in the seas, still maintains for its cellular existence the same original environments; in other words, every organism, whatever its rank in the animal scale, is essentially a colony of marine cells. The first part of his proposition, that animal life had a marine origin, is sufficiently probable to be accepted; the primitive gill respiration, which he adduces as evidence, appears through the whole series of higher forms of animal life in its embryology, and all the simpler forms are of an aquatic type. The experimental evidences he offers of his main thesis are the successful displacement of all or the greater part of the blood of dogs by sea-water without causing death or damage other than necessarily due to the operative steps, and the persistence of the vitality of the white blood-corpuscles of all classes of organisms in the same medium, which he claims to have demonstrated. Lastly, he offers as evidence the identical chemical composition of the blood plasma and sea-water. The salts of the one are the salts of the other, seriating moreover in the same order of importance, viz., 1, sodium, chlorin; 2, potassium, calcium, magnesium, sulphur; 3, silicon, carbon, phosphorus, fluorin, iron, ammonia and iodin. Still further, he claims sea-water and blood contain in like proportion minute quantities of other elements, such as bromin, manganese, copper, silver, lead, lithium, etc. This may not be an ab[illegible]tely novel conception; it may possibly ha[illegible] to others, but we have not seen it p[illegible] and prominently elsewhere. It is practical ways; sea-salt normal solution, or sterilized sea-water itself, may turn out to be the best restorative and it is still further suggestive in connection with the comparatively recent researches of Morgan, Loeb, and others on the parthenogenetic development of certain organisms in differently modified marine media. There is possibly a large field for study and work in the direction here indicated.

ERGOGRAPHIC TESTS IN SCHOOL CHILDREN.

The article by Dr. Christopher, published in this and the preceding issue of THE JOURNAL, treats of a subject that has a more than passing interest. The welfare of the child, and especially at the critical period of puberty, is an important matter and it is easily seen how faulty educational methods may have a damaging influence that will be felt through all the future life of the individual. Dr. Christopher has utilized the methods of modern physiologic research and has availed himself of the services of assistants skilled in instrumental psychologic experimentation, which would naturally add to the value of the observations. From this study he demonstrates already some facts that are suggestive, if not conclusive, such for example as that shown by the power curve through the school-day and the corresponding ergograms. It is apparent, at least, that the child needs more frequent respite from school duties than is always given by modern pedagogues. School-teachers are liable perhaps more than others to become opinionated and arbitrary, hence the need of their proper instruction on matters that concern the welfare of their charges. It would be well, therefore, could they generally study such articles as that of Dr. Christopher, which illustrates by graphic methods the effects of mental work on muscular and nervous endurance. At present we have a strong suspicion that some popular teaching methods are unphysiologic and liable to produce serious effects by the overstrain of immature and, therefore, especially vulnerable organizations. The paper we publish is essentially a preliminary one, as the investigation is still being carried on. That it involves a possibility of important and beneficial results needs hardly to be stated.

MYOSITIS OSSIFICANS.

The calcareous degeneration of certain tissues is a well-known fact, but the formation of true bone in the tissues, not normally thus developing, and apart from any direct connection with the natural bony growths, is still to some extent a pathologic curiosity. This is especially true of the ossifications of the muscles, of which a comparatively small number of cases have been reported in medical literature. Dr. Lydia M. Dewitt reports[1] a case, with the discussion of the literature of this subject, in part honestly acknowledged as second-hand, with the theories that have been proposed to account for the condition. The fact that in certain animals the so-called splint bones occur has a certain physiological bearing, but the facts do not fully apply to the human subject. The curious malformation that has been observed in some 75 per cent. of the recorded cases of this disease of microdactylia and imperfection of the thumb and great toe is of interest, and is one of the unexplained but indefinitely suggestive peculiarities that we sometimes meet with in connection with obscure diseases. Dr. DeWitt's idea seems to be that on the whole the condition is not so mysterious a one as might be supposed. The fact that different members of the connective-tissue group change with special readiness into other forms of connective-tissue structure is, she holds, a probably sufficient explanation, lacking others a little more definite. She does not consider the suggestion of Gegenbaur, of specialized osteoplastic nuclei existing from before birth, as necessary to account for the pathologic bone formation. The cells which in certain regions act as osteoblasts are not, she thinks, necessarily histogenetically different from those which in other localities develop into fibrous connective tissue. The subject is by no means definitely cleared up, but her communication is a reasonable discussion of the facts and probabilities.

THE DISASTER AT GALVESTON.

The terrible disaster at Galveston, the reports of which have as yet only partially reached us, seems likely to be one of the worst on record, exceeding even Johnstown in loss of life and property. If commercial reasons make it inevitable that we shall build our cities where they are subject to such disasters as those that have twice afflicted Galveston, it would seem necessary that some special measures should be taken to ensure their protection. The building of houses directly in the sand, where they are liable to be flooded, appears to court disaster, and the chances for such a hurricane, even only once or twice in a century, should be kept in mind. The results of the catastrophe, aside from the direct mortality, are most serious, as there is said to be an immense number of injured and maimed, and the sanitary conditions, as in Johnstown and Titusville, following such a flood require thorough and immediate attention. This is a matter of more importance in the latitude of Texas than it would be farther north. More than this, the survivors, in their wrecked and dismantled homes, are exposed to still other perils and hardships, the water-supply is cut off, and, hence, the dangers of fire and of a water famine are also imminent. With all these things to affect the health, there is yet the moral effect of such a catastrophe, which can not well be estimated, but which can only be a factor in the total outcome of the misfortune. The revival of the city is, we trust, beyond question; and the injury it has received we hope may prove to be only a temporary one. It should and will have the active sympathy and aid of more fortunate sections of the country. It is to be hoped that engineering skill will, in repairing the mischief that has been done, find a way to insure against a repetition of the calamity.

THE LATEST DECREE OF THE ANTIVIVISECTIONISTS.

Among the numerous Congresses held in Paris during the past summer, there was one called the International Congress of Animal Protection Societies. While not ostensibly in the interests of the antivivisectionists, it was evidently captured by them. A resolution was introduced stating that "vivisection is a crime unworthy of the toleration of any people calling themselves civilized." A separate vote was taken of the anti-cruelty societies, and in them it was voted down, as they simply worked to restrict, not to abolish vivisection. The vote of the antivivisection organizations, which predominated in the Congress, was, however, so overwhelming that the resolution was carried by a majority of about two to one, so that, as one John Vedder, M.D., whose statement of the facts we follow, holds the "minds of the International Congress of Animal Protection Societies was for the total prevention of vivisection." This he claims as a great victory. The meeting was apparently an obscure one, as we have seen no mention of it elsewhere than in this communication to the *Boston Transcript*, but it is of sufficient medical interest to be mentioned here; it is well to know what the enemy is about. If the antivivisectionists and zoöphiles can so have their way, they will in time make it a greater crime to sacrifice an animal for the benefit of mankind than to murder one of their own species. Human life is little regarded by their co-believers in India, who butchered Englishwomen in Cawnpore, and the prejudices of the Hindoo population in this direction have created some of the most serious obstacles to the successful combating of the plague amongst them. The European and American antivivisectionists seem really little more open to reason than are their Asiatic confrères, and they certainly show a like intolerant spirit. There is nothing so inhuman as idolatry, and the individual who sets up a fad as his divine image and demands that others as well as himself shall bow down to it, is, in his way, as benighted a pagan as Nana Sahib or the Chinese Boxer of to-day.

---

A UNIFORM CLASSIFICATION FOR HEALTH STATISTICS.

Elsewhere in this issue—on page 705—will be found a brief report of the late session of the International Congress of Hygiene and Demography and its action regarding an international classification of diseases. The advantages of such an universal system are obvious if the data are to be utilized, and it may be that the Paris classification adopted is a good one for this purpose. It is not above criticism, however, for it appears to us, as given in the mortality reports in the Paris journals, as deficient in several respects. The only forms of nervous disorders included are: cerebral hemorrhage and congestion, paralysis, softening of the brain and simple tuberculous meningitis, that is, if we accept the classification as published in the Paris medical journals. It is possible that the arrangement is extended in the original records and the 15 or 20 per cent. of "other causes of death" lump together many cases of tabes, paresis, epilepsy, angina pectoris, and various other affections from which Parisians are certainly not exempt. Unless this is the case, and we can only assume that it is, in these and some other respects some of our American municipal classifications appear preferable, and it is to be feared that the recommendation of the Congress will not at once be universally accepted. The fact that it was composed, to a large extent, of laymen and that the largest number of medical delegates were probably Parisian, or at least French, may account for the selection of this system. If the one chosen is to be generally adopted, it is to be hoped that some provisions are to be made for the possibility of its early modification, provided that its apparent defects above noticed are not merely apparent ones. While an international system is a desideratum, it would be well if in our own country a more uniform system could be adopted by the different state and local authorities in making out the reports on which are based our mortality statistics. A uniform system of reports based on the best now used would be much more valuable in every way than the present unscientific lists that are sent out by many health boards. This is a subject worthy of consideration on the part of health officers, and others interested in health statistics.

Medical News.

ALABAMA.

Dr. Irwin W. Patton, of Huntsville, has been appointed acting assistant-surgeon in the army, and directed to report for duty to the commanding officer of the United States forces in China.

ARIZONA.

Dr. G. W. Greenleaf, of San Diego, Cal., has been appointed physician of the Fort Young Indian School, Yuma, vice Dr. William T. Hefferman, resigned.

The Sanatorium at St. Mary's Hospital, Tucson, will soon be ready for occupancy. It is a building in pavilion style, with twenty-four rooms, sanitary arrangements of the latest model, and will cost about $25,000.

CALIFORNIA.

Dr. William H. Flint has returned to Santa Barbara and resumed practice.

Dr. Fisher R. Clarke has returned to Stockton, after a two months' trip to Cape Nome, Alaska.

Dr. Barton Dozier and Miss Mary D. Boynton, both of Los Angeles, were married on August 27.

San Diego had only fifteen deaths in July, "thirteen white, one black and one yellow." No contagious disease exists in the city.

Dr. Alden M. Gardner, medical superintendent of the Napa Asylum for the Insane, will, it is reported, soon resign and establish a private sanatorium in the Ralston mansion, at Belmont.

"Helminthologists" are in trouble in Los Angeles because they have been practicing without first obtaining the required license to practice medicine in the state. "Dr." Genaro Yglesias was arraigned, and after making a strong fight, was finally convicted and fined $200 and costs.

The health officer of Jackson reports that on August 24 twelve houses were under quarantine for smallpox, with ten cases of the disease, all the patients being convalescent. Ranlett Station had one smallpox case, and neither Sutter Creek nor Rancheria Creek reported any spread of the disease.

The board of health of San Francisco has endeavored to obtain possession of a fund of $4000 reserved for epidemics, on the ground that there is one smallpox case in the isolation hospital, but the supervisors have refused to turn over the money, claiming that it was to be used only in case of the outbreak of an epidemic.

Dr. W. M. S. Beede, who for the last four years has been in the Orient, first as U. S. consular surgeon at Hongkong for three years, where he went through two epidemics of bubonic plague, and then as chief surgeon of the National Red Cross Hospital at Manila, has returned to Stockton and will resume practice there.

It is reported that five hospital tents are to be put up at the Presidio to accommodate the overflow from the General Hospital there. The San Jose *Mercury*, in commenting on this report, recommends the Berkeley hills, and condemns the present location, stating that "there is no excuse for a general hospital at the Presidio."

Mentone, San Bernardino County, is to have a new sanatorium. Several Los Angeles physicians, including Drs. William M. Lewis, Ralph Hagan and Josiah E. Cowls, have recently inspected a large tract of land on which it is proposed to erect a sanatorium, which the promoters claim will be one of the finest in the state.

A sanatorium for consumptives is to be established in Strawberry Valley, San Jacinto, by the California Health Company, at a cost of $50,000 to $60,000. The plans contemplate a center pavilion with forty bed-rooms, lounging, smoking, reception and consultation rooms: this pavilion to be surrounded by small cottages. Half a mile away a small village of cottages is to be built for patients who wish to do housekeeping in a small way.

The employees of the Southern Pacific Railway at Oakland have made a vigorous demand for prompt care of the injured. They claim that since the establishment of the main hospital for the company in San Francisco many injured men have been forced to wait and suffer for hours before removal to the hospital. Before the company abandoned its hospital work in Oakland, it is said, prompt ambulance service and hospital attention were rendered the sick and injured.

The report of the State Hospital for the Insane at Stockton shows that for the year ended June 30, 1900, the total number of patients under treatment was 1397. Of these, 96 were discharged as recovered, 35 as improved, 11 as unimproved, and 2 as not insane. The deaths were 154, and 9 escapes were reported. Of the 319 patients admitted during the year, 173 were native-born, and 30 of these were Californians. The causes for the insanity are given as follows: Intemperance, 23; religion, 6; morphinism, 4; "living alone and drinking unfermented wine, 1; "fear and excitement during initiation to a lodge," 1; "association with fortune-tellers," 1; "worry and wanting to get married," 1.

COLORADO.

Dr. Carey K. Fleming, of Denver, secretary of the State Board of Medical Examiners, was elected president of the Rocky Mountain Interstate Medical Association, at its recent meeting at Butte, Mont.

Three thousand school children in Denver have been vaccinated during the last weeks preceding the opening of the schools. Extra precautions in this regard are being taken by Dr. Thomas J. Carlin, health commissioner, on account of the prevalence of smallpox throughout the country.

The State Board of Health, in its latest circular, defends itself against the charges that it is persecuting consumptives and trying to run them out of the state, and quarantine against consumption. It disavows these charges and claims that its endeavors are solely to aid consumptives, as well as others. To this end it has promulgated rules for the education and guidance of consumptives.

CONNECTICUT.

Dr. Dean Foster, who was removed from the house staff of the New Haven Hospital for an infraction of discipline, which was apparently justifiable, has profited by his misfortune. He has been appointed resident surgeon at St. Vincent Hospital, New York City.

The regular practitioners of New Britain, indignant at being unrecognized by the corporators of the hospital at that place, treated with contempt by the directors, ignored by the executive committee, and snubbed by the matron, called a meeting, presided over by Dr. Samuel W. Irving, at which the following resolutions were passed: Resolved, that the members of the regular medical profession are entitled to at least one-third representation on the board of directors of the New Britain General Hospital, and that one of those aforementioned representatives should be a member of the executive committee of said institution; resolved, that the regular medical profession of New Britain nominate from its members a medical and surgical staff, and that said staff should have control of all things pertaining to medical and surgical matters.

DISTRICT OF COLUMBIA.

The Georgetown Hospital was the beneficiary of a lawn-fête, held on the campus of Georgetown University, September 4, 5, 6 and 7.

The two representatives of the medical department of the army, at the meeting of the American Public Health Association, at Indianapolis, October 1 to 5, are Major Charles Richard and Major William O. Owen.

The commissioners are meeting with difficulties in their efforts to secure a site for the new municipal hospital. They found a wide divergence between the prices asked for land and the ordinary valuation of the same property. This may act as a boomerang, as property-owners may be asked the reason for low assessments and tax payments on land which, under the present circumstances, they hold at so high a figure. Meanwhile matters regarding the hospital are at a standstill.

The District health report for the week ended August 30 showed a decided improvement over that of the previous week. Deaths amounting to 106 occurred in the week, making an annual death-rate of 13.71, as compared with 21.88 per 1000 for the week ended August 23. Typhoid fever caused 4 deaths, and 1 death occurred from whooping-cough. There were held in quarantine 33 cases of scarlet fever and 25 cases of diphtheria, an increase over the figures of the preceding week.

FLORIDA.

Dr. S. H. Woods, a graduate of University Medical College, Kansas City, has settled in Fort Meade for practice.

GEORGIA.

Dr. Harry M. Clarke, of Milledgeville, who moved to Atlanta early in the year, has returned to Milledgeville and resumed practice.

Dr. James F. Alexander, of Atlanta, one of the oldest practitioners in the city, has retired from practice on account of the rapid failure of his health.

The quarantine station at Savannah has been sold to the United States Marine-Hospital Service for $20,000. Since 1898 the station has been under the charge of the marine-hospital officials, pending report of the arbitrators appointed to fix the value of the station. Health Officer Brunner says that the station is the largest and the most important yet acquired by the Marine-Hospital Service, and should add to the prestige of that branch of the government service. If the results are good, it will lead to the acquiring of other stations, and it is therefore both the interest and the duty of the Marine-Hospital Service to give Savannah the best service of which it is capable.

ILLINOIS.

Dr. Merritt S. Jewell, of Olena, has removed to Little York.

Dr. Edgar E. Kilby has removed from Emden to Congerville, Woodford County.

Dr. Charles L. Koch, of Quincy, was married at Pittsburg, Pa., August 28, to Miss Susie E. Long, of that city.

Dr. J. R. Allen, of Custer, who has been suffering from a severe attack of appendicitis, is slowly recovering.

Dr. George E. Barth, who has practiced medicine in Rock Island for a quarter of a century, will remove to St. Louis.

Dr. L. D. Rockefeller will locate in Kewanee and will succeed Dr. John Murchison, who has removed to a mining town near Galesburg.

The barn of St. Joseph's Hospital, Joliet, the north end of which was used as an isolation ward, was seriously damaged by fire on August 28.

A partnership has been formed by Drs. Henry Hatch and John H. Rice, of Quincy. During the absence of Dr. Hatch, who sails for Europe in a few days, Dr. Rice will attend to the practice.

St. Clement's Hospital, Red Bud, is now ready for the reception of patients. The hospital is a three-story brick structure, is heated by steam and is elaborately equipped in every department.

Chicago.

Dr. William M. Harsha has returned from his vacation trip to Europe.

Dr. Albert B. Hale is lying seriously ill with typhoid fever at the Baptist Hospital.

The Post-Graduate Medical School has increased its capital stock from $20,000 to $40,000.

Dr. John A. Robison and wife have returned from their summer outing at Algonquin, Mich.

Dr. Henry T. Byford and family have returned from their summer home at Crystal Lake, Wis.

Drs. Homer O. Bates and Laura C. Bates have returned from their summer outing at Thousand Islands, N. Y.

Mount Sinai Hospital has been incorporated by Drs. Rudolph Menn, George M. Silverberg and Adolphus E. Berting.

Dr. Thomas Hughes was married to Miss Rose Myrtel Wakely, of Milwaukee, at St. John's Cathedral, September 5.

Dr. Morley Da Costa Bates, son of Dr. Homer O. Bates, was married to Miss Edith Gray Brown, also of Chicago, on August 29.

Boulevard Sanitarium has been incorporated with a capital stock of $2500, by Drs. Harry J. and Wellington T. Stewart and W. Clark Allen.

Harvey Medical College officers tendered a reception to the faculty, graduates and students on September 3. The lectures for the new term commenced on September 4.

The first regular meeting of the Chicago Gynecological Society for the year 1900 will be held in the Chicago Medical Society rooms, Friday, September 21, at 8 p.m.

Drs. A. J. Ochsner and A. H. Ferguson have been appointed professors of clinical surgery in the medical department of the University of Illinois—College of Physicians and Surgeons.

Dr. Archibald Church has been recently appointed professor of nervous and mental diseases and head of the neurological department of the Northwestern University School.

Dr. George P. Dreyer, associate professor of physiology at Johns Hopkins Medical School, has been elected to the chair of physiology in the College of Physicians and Surgeons, and will take up the duties of his new position October 1.

HEALTH DEPARTMENT.

The health department has been notified that it has been awarded one of the grand prizes at the Paris exposition for its exhibit of blanks, charts and other forms in use at the office of the department.

Bubonic plague is the text of an exhortation of the commissioner of health to the city and people to keep streets, alleys, homes and public buildings scoured and clean. He does not believe that the disease will gain a foothold even in the coast cities.

Controlling works at the junction of the river and the Sanitary Canal are favored by the health department, which deems such works necessary. At present it requires from eight to twelve hours to shut the gates at Lockport and stop the current, and during this time the garbage and sewage is prevented from taking its natural course through the canal, and the health of Chicago is thereby endangered.

Computed on the Federal census figures of Chicago's population—1,698,575—the death-rate of the last two weeks is 13.60 per thousand per annum, as against 15.75 per thousand for the corresponding period of 1899. This latter rate is computed on 5.44 per cent. less population than that of 1900. Since the unprecedentedly hot week of August 11, the weekly number of deaths has steadily declined, so that the total mortality for August—2138—is only 66 in excess of the average August mortality—2072—of the previous five years, and is 123 lower than for August, 1896. Should the present favorable condition of the public health continue through September, the total deaths for the year will hardly exceed those for 1899, notwithstanding that the first seven months indicated a much higher total. Deaths from the impure-water diseases continue to be gratifyingly few as compared with former years, the total for the last two weeks being 218, as against 269 for the corresponding two weeks of last year. Except for an unusual number of deaths from suicide and other forms of violence there is either no noteworthy increase or an actual decrease in the deaths from the principal causes. The deaths reported for the week ended September 1 were 443, or 32 less than for the corresponding week of last year; the death-rate per thousand was 13.70 as compared with 15.40 for 1899. Of males, 251, and of females, 192, died. The deaths of children under 1 year of age were 116; between 1 and 5 years, 56, and over 60, 67. The principal causes of death were: Acute intestinal diseases, 111; consumption, 40; violence, 39; pneumonia, 23; heart diseases, 22; nervous diseases, 18; Bright's disease, 16; cancer, 15; suicide, 10; typhoid fever, 6, and sunstroke, 4. During the week 628 births were reported. The total deaths for the week ended September 8 were 444, or 52 less than for the corresponding week of 1899. The death-rate per thousand was 13.61, as compared with 16.09 for last year. By sexes the deaths included 255 males and 189 females. By ages, 122 died, under 1 year of age, 51 between 1 and 5 years, and 68 over 60 years. The chief causes of death were: Acute intestinal diseases, 94; nervous diseases, 40; consumption, 39; violence, 39; heart diseases, 38; pneumonia, 16; cancer, 14; suicide, 12; typhoid fever, 7, and sunstroke, 2. During the week 562 births were reported. In the laboratory 139 bacteriological examinations were made; 10,540 vaccine tubes distributed; 100 antitoxin treatments given, and 339 samples of milk examined, 10.62 per cent of which were below grade. At the stockyards, 66,996 pounds of meat were condemned.

INDIANA.

Dr. William B. Blackstone, of Crown Point, will remove to South Bend.

A partnership has been formed by Drs. Samuel G. Todd and Edgar A. Doan, of Mishawaka.

The State Medical Board reports that 6115 physicians have thus far been registered in the state.

Dr. W. R. Amick, of "consumption cure" fame, died from heart failure at Columbus, August 30.

More than six hundred physicians have registered and are licensed to practice in Marion County.

Impetigo contagiosa is reported to be epidemic in Indianapolis, where it has commonly been mistaken for tinea sycosis.

Dr. F. W. Brown, assistant medical examiner for the Pennsylvania Volunteer Relief Association, has had his headquarters removed from Logansport to Fort Wayne.

Dr. D. R. Brower, of Chicago, delivered an address at La Fayette, September 5, before the Tippecanoe Medical Society, on "New Things in Neurology, and Diagnosis and Treatment of Locomotor Ataxia." Stereopticon views were utilized to illustrate the important points.

The new buildings of the Longcliff Hospital, the Northern Indiana hospital for the insane, at Mishawaka, were formally opened on August 28, in the presence of Governor Mount, other high state officials and invited guests. Several hundred insane patients, who have been confined in the county jails and asylums of this district for lack of accommodation in the state institution, will be transferred to the new ward building.

IOWA.

Dr. Harold Bailey, of Charles City, has started for Europe, where he expects to spend a year in study.

Dr. J. H. Stanton has disposed of his practice at Harper's Ferry and has moved to Prairie du Chien, Wis.

Dr. Jesse B. Buck, of Iconium, has purchased the practice of Dr. L. T. Goisuch and will move to Moravia.

Dr. Frank La Force, of Ottumwa, is serving an interneship in the Illinois Charitable Eye and Ear Infirmary.

Dr. Lorenzo T. Gorsuch, of Moravia, has sold his practice on account of ill health, and will go to either Colorado Springs or Oakland, Cal.

Dr. Howard W. Seager, of Des Moines, has been appointed an acting assistant-surgeon in the army. He served as hospital steward in the Philippine campaign.

The physicians of Mason City held a meeting on September 3 to consider the question of a city hospital, and appointed a committee to look into the matter. Two sites for the proposed hospital have been offered gratis, and there seems to be no doubt that the funds for erecting and equipping the hospital will be quickly raised.

Muscatine County has been sued by Dr. F. E. Schmidt, of Muscatine, for $575, for services rendered during the recent smallpox epidemic in that city. The petitioner sets forth that during March, April and May, 1900, he was employed by the board of health to disinfect places and houses where smallpox patients had resided, or had been kept, and that his bill had been disallowed by the board of supervisors of the county.

KANSAS.

The College of Physicians and Surgeons, Kansas City, was formally opened on September 4, at Sixth street and Ann avenue.

The employees of the ice plant and packing house have contributed $50 and fitted up a room in the new hospital at Winfield.

Dr. Hubbard Linley, of Atchison, has been appointed to the chair of accidental and orthopedic surgery in the Central Medical College, St. Joseph, Mo.

Suit has been brought against a physician of Topeka for $5500. The complainant avers that his ankle was dislocated, was not properly set and that he is now a cripple.

MAINE.

Dr. E. H. Doble, a graduate of the Baltimore University School of Medicine, has located in Presque Isle.

Dr. Blanche Mansfield, of Old Town, a graduate of the Woman's Medical College of Philadelphia, will practice in Bangor.

Dr. John F. Hill, who was elected governor of Maine on September 10, is the second medical man to preside over the affairs of the state. In 1878 Dr. Alonzo Garcelon was elected governor, being the only democrat ever elected to that office in Maine. Governor-elect Hill was born in Eliot, in 1860, was graduated from Bowdoin Medical School in 1877, and ten years later took another course and received a diploma from Long Island College Hospital, Brooklyn. After a few years of practice he retired and became interested in various industrial enterprises in the state. He has been a member of the state legislature since 1892.

MARYLAND.

Dr. John H. Jamar, of Elkton, Cecil county, has inaugurated a movement for a drinking fountain in that place for man and beast.

Dr. William J. Todd has been appointed surgeon for the Northern Central railroad, at Mt. Washington, to succeed the late Dr. Josiah S. Brown.

At the annual graduating exercises of the Nurses Training School, connected with the Western Maryland Hospital, at Cumberland, on September 6, three nurses were graduated.

The ease with which deadly poisons can be purchased in this state for suicidal or homicidal purposes has been emphasized by the recent death of a young woman from morphin. There is no law in Maryland restricting or safeguarding in any way the sale of poison. Maryland is the only state without a pharmacy law. Legislation only extends to requiring druggists to qualify and become registered. The State Board of Pharmacy is taking steps to have this amended so as to have a complete law.

Baltimore.

Dr. James Bosley, health commissioner, has gone for a two-week's vacation to the Great Lakes.

Dr. Henry M. Hurd, superintendent of Johns Hopkins Hospital, will spend the month of September at Charmion, Pa. During his absence Dr. Andrew H. Whitridge will have charge of the Hospital.

Dr. Pierre G. Dausch has been sued by a widow for $20,000 damages. She alleges that on September 10, 1899, the doctor performed on her husband a surgical operation from the effects of which "he became sick, sore and disordered, and in consequence thereof, died on or about Sept. 14, 1899."

Dr. Flora A. Brewster has been indicted by the grand jury on a charge of establishing and keeping an asylum for the care of the insane at 1221 Madison avenue, without first obtaining a license from the state lunacy commission. Dr. George J. Preston, secretary of the Lunacy Commission, was the principal prosecuting witness.

Suit has been brought against Dr. Joseph C. A. Wunder for $10,000 damages. The suer alleges in his bill that he ran a splinter of wood into his hand and went to Dr. W. for treatment; that after being treated by the latter he failed to obtain relief, but was relieved by other professional skill. He also charges that an operation done by Dr. W. caused him to lose the use of a finger. Dr. Wunder says when the case comes to court he will be able to prove that his treatment of the case was correct.

Health Commissioner Bosley will not recognize, at least for the present, the population of this city as given by the U. S. census bureau, but will continue to estimate the mortality on a figure about 32,000 in advance of the census figures. The death-rate for the week ending September 1 was 19.70—whites, 18.53, colored 26.66—per thousand. Of these cholera infantum caused 25 deaths; consumption, 30; dysentery, 11; Bright's disease, 18; heart disease, 9; typhoid fever, 7, and diphtheria, 3.

MASSACHUSETTS.

Dr. Joseph H. Broadbent, Jr., of Roxbury, has been appointed pathologist at Roosevelt Hospital, New York City.

Dr. William A. Jackson, Jr., of Haydenville, has sold his practice and property to Dr. Victor S. Merritt, of Hartford, Conn.

Dr. Lionel A. B. Street, of Brookline, acting assistant-surgeon, U. S. A., who is now on his way to the Philippines, has been ordered for duty with the corps of engineers.

Dr. Frederick T. Clark has resigned his position at the state hospital at Poughkeepsie, N. Y., and will locate in his home, Westfield.

A large tract of land on Mount Auburn street, Cambridge has been transferred by the Cambridge Hospital to Harvard University. It will be used as the site for the new infirmary.

Dr. Carl E. Sleeper, a graduate of Dartmouth Medical School of 1900, has been appointed interne at the Burbank Hospital, Worcester, to succeed Dr. R. C. Cross, resigned.

Morton Hospital at Taunton has a thoroughly equipped operating annex. It includes a sterilizing plant and a special operating, anesthesia, recovery and accident rooms. It now asks to have two new wings built, one at either side of the main building.

Vaccination is called "assault" in New Bedford, the question being whether a physician of the board of health has the right to vaccinate a child against the wish of its parents. Dr. J. P. St. Germain, who was engaged in house-to-house inspection and vaccination, is said to have vaccinated two children against the wish of their parents. They have applied for a warrant for the vaccinator's arrest on a charge of assault and battery.

New Bedford is now going through the experience many Western states have had, and is agitated by the question whether its epidemic disease is chicken-pox or a mild form of smallpox. Little quarantine has been maintained and there are grave apprehensions as to the real nature of the disease. The board of health is now taking active measures to stamp out the malady.

MICHIGAN.

Dr. Harry S. Kiskadden, of Detroit, has been appointed health commissioner to succeed Dr. B. Howard Lawson, resigned.

Dr. A. Bruce Henderson, of Detroit, has been appointed acting assistant-surgeon in the army, and has sailed for the Orient.

The mortality of Detroit for the week ended August 18 was 113, 55 being children under 5 years of age. During the same period 56 births were reported.

Detroit reports 4927 deaths for the year ended July 1. Of this number 460 were due to pneumonia, 159 to cholera infantum, 34 to suicide, and 2 to murder.

The Woman's Hospital and Infants' Home, at Detroit, has been incorporated; this is merely a change of name from the Woman's Hospital and Foundlings' Home, and means only a reorganization.

Ludington physicians refuse to accept the appointment of health officer, because the salary has been fixed by the city council at $300. During the first half of the year there were six deaths in the city from preventable diseases.

MINNESOTA.

Dr. Ralph J. Sewall, of Two Harbors, expects to have his hospital ready for patients this month.

Dr. Alexander J. Stone, of St. Paul, will probably receive the democratic nomination for congress.

Dr. C. James Beise, formerly of Tracy, who has been taking a post-graduate course at Johns Hopkins Hospital, Baltimore, has located at Fergus Falls.

Norwegians in St. Paul have started a movement toward the establishment of a hospital for their countrymen. Dr. Eduard Boeckmann and others have organized committees to obtain funds for this purpose.

The public baths at St. Paul, established and efficiently managed by Dr. Justus Ohage, health commissioner, reflect great credit on the discernment and executive ability of that officer. Over 213,000 have bathed at Harriet Island; in the hot weather as many as 6000 to 10,000 a day have bathed there. The cost of the establishment has been less than $10,000.

Dr. Henry M. Bracken, secretary of the state board of health, makes the serious charge against Dr. Aretus K. Norton, health commissioner of Minneapolis, that owing to his failure to recognize smallpox, and properly quarantine, the disease has spread throughout the city and into the state. Up to July 1 there had been 377 cases of smallpox in Minneapolis and 359 at various points in the state directly traceable to Minneapolis, it is said. Cases at Janesville, Wis., and Wahpeton, N. D., had also been traced to this source.

MISSOURI.

Dr. W. E. Minor and family have returned to Kansas City from their trip abroad.

Dr. Joseph M. Harris, of Sedalia, is candidate for coroner on the republican ticket.

Dr. Charles W. Fassett and Dr. William T. Elam, of St. Joseph, have returned from their European trip.

Dr. Robert W. Renwick, of St. Louis, was married to Miss Blanche G. Becker, of St. Charles, at Belleville, Ill.

The University Medical College, Kansas City, has taken out a permit to construct an addition to the college, to cost $7000.

Central Medical College, St. Joseph, has opened with an attendance of more than forty. The fall term of Ensworth Medical College will commence September 17.

Dr. Herman L. Nietert, superintendent of the City Hospital, St. Louis, maintains that the surgical division of the new hospital should be able to accommodate 98 acute and 237 chronic cases, and that two wards should be provided for the detention of male, and two for female criminals.

The new hospital, for which $258,000 has just been appropriated, will not suffice, says President McMath, of the board of improvements, St. Louis. He claims that it will do for emergencies, but will "come far short of providing hospital accommodations that will enable the temporary city hospital to be vacated."

NEBRASKA.

Dr. Andrew Crawford, of Omaha, has removed to Harrisburg.

Dr. Lee Van Camp assumed his duties as physician of Douglas County, September 1. Dr. W. J. Redfield Ryan has been appointed to the interneship in the county hospital made vacant by Dr. Van Camp's translation.

Omaha needs an emergency hospital, and Dr. Victor H. Coffman, health commissioner, is endeavoring to persuade the city council to erect one before the advent of winter. The necessity is the more urgent in view of the possibility of a smallpox epidemic.

NEW JERSEY.

Col. George P. Olcott, of East Orange, has been appointed a member of the State Board of Health, to succeed the late Dr. Gaunt.

The managers of the Children's Seashore Home in Atlantic City are endeavoring to keep the house open until the middle of September in order to accommodate the large number now present there. They, however, report that up to this time the funds are insufficient, and an additional $1000 is asked for.

Dr. R. H. Parsons, of Mount Holly, president of the local board of health, has made a formal complaint to the New Jersey State Board of Health regarding the contaminated water furnished the city. The drinking water has been condemned by the local physicians, and an epidemic of typhoid fever is feared. Several cases have so far been reported. The present water-supply is obtained from Ranocas Creek, and it has become so low that pools had to be dammed up in order to get a sufficient supply. It is now stated that in many of these pools the water has become stagnant.

NEW YORK.

Dr. Julius E. Haight, of Matteawan, has been appointed medical interne at the State Hospital for the Insane at Utica.

The Unadilla Valley Medical Association was entertained at dinner at New Berlin on August 14 by Dr. and Mrs. J. B. Noyes.

Dr. Reid Gilmore, of the Cohoes Hospital, has been appointed house physician at the Ellis Hospital, Poughkeepsie, and has assumed his new duties.

The library of Syracuse University College of Medicine has received a bequest of sixty bound volumes and a number of pamphlets from the professional library of the late Dr. S. G. Ellis.

The main building of the New York State Hospital for Insane Criminals at Dannemora will be opened very soon. It is about 300 by 40 feet, two stories high, and has about 300 cells. Dr. Albert B. Lamb, of Matteawan, will be superintendent.

The women of Syracuse University College of Medicine have organized, during the past year, Zeta Phi, the first and only women's medical fraternity in this country. They esteem it an honor that Dr. Elizabeth Blackwell has consented to become a charter member, she having been graduated from this college and the first woman to receive the degree of M.D. in America. The purpose of the fraternity is to bring the women of the medical profession into closer touch with one another.

Buffalo.

The medical department of the University of Buffalo will open its fifty-fifth regular session on September 24.

Both the mayor and the postmaster of Buffalo are practicing physicians. Dr. Conrad Diehl is mayor and Dr. Samuel G. Dorr is postmaster.

The German Hospital will soon be completed. It is situated in the geographical center of a very large German population, and is modern in all its arrangements.

Dr. Marcel Hartwig, recently elected president of the Buffalo Academy of Medicine, has offered a prize of $50 for the best essay on a scientific subject, to be presented during the season of 1900-1901 by a fellow of the academy.

The health commissioner is trying to abate the nuisance due to the wetting and consequent fermentation of more than 600,000 bushels of *grain* which were *in the elevators* recently burned. Many complaints of nausea, vomiting [illegible] diarrhea have been made by the men wor[illegible]nd the effects of the stench on infants [illegible] be most deleterious.

The health report for July shows the annual death-rate to be 15.60 per 1000. There were 31 deaths from consumption, 24 from cancer, 94 from cholera infantum, and 25 from nephritis. The total number of deaths was 458—226 male, 232 female—as compared with 486 for the same period last year. The number of deaths under 5 years was 201, and 52 were over 70 years of age.

Dr. Ernest Wende, health commissioner, has called the attention of the councilmen to the urgent necessity of a new and commodious quarantine hospital. The present structure has outgrown its usefulness. The necessity is the more urgent in anticipation of the cosmopolitan crowd which will assemble in Buffalo during the Pan-American Exposition and the great danger resulting from a possible outbreak of contagious disease at that time.

The New York State Pathological Laboratory has secured the services of Mr. Clowes, of London, England, as chemist. The laboratory, which has already attained an international reputation for its original research work on the etiology of cancer, is a part of the University of Buffalo, and its present location is in the Medical College building. The director and his assistants have been very much hindered in their work by reason of the crowded quarters. Recently a bequest of $25,000 was made for the erection of a new and modern laboratory building. Enough money has already been collected by private subscription to buy a suitable site, so that a new building is assured in the very near future.

New York City.

Dr. Virgil P. Gibney and wife have been visiting for several weeks with friends in various parts of Kentucky.

Dr. Louis L. Seaman, late major-surgeon of the 1st U. S. Volunteer Engineers, arrived in New York September 1, after a short European trip.

On September 5, Dr. Godfrey Rogers Pisek was married to Miss Rosalie Scranton Paul, daughter of the late Dr. F. M. Paul, of Belvidere, N. J.

The prison commission will formally urge the hospital commission to select Dannemora as the site for the proposed State Hospital for Consumptives.

Ten physicians and twenty trained nurses from Bellevue Hospital started for Galveston, September 11, to assist in caring for the sufferers from the storm which devastated that city.

Two of the public baths, both well patronized, have been moored all the season almost directly at the mouths of sewers. There is little excuse for such gross carelessness, but it is comforting to read that immediate steps were taken to close the baths.

At the annual meeting, on September 6, the following were elected officers of the prison commission: President, Lispenard Stewart, New York City; vice-president, Nelson Davenport, Troy. Secretary McLaughlin was elected for a third term.

Dr. Justin Herold, an authority on legal medicine, and editor of a text-book on that subject, has brought suit against the Metropolitan Street Railway Company for $100,000, for injury to his right leg, sustained in a collision between two street cars on May 31. It is alleged that the injury was such that he will be a cripple for life.

The isolation of consumptives in the hospital on Blackwell's Island, after the removal of the insane patients therefrom, is a plan which Commissioner Keller is endeavoring to carry through. This will place the present phthisis ward at Bellevue Hospital at the disposal of the authorities for other work.

A boy, 13 years old, died a few days ago in the Harlem Hospital, of hydrophobia, according to the *Medical Record.* He was attacked while playing in the street by a dog, which bit his nose off. The first symptom of rabies appeared seventeen days later. It is stated that this is the seventeenth death from rabies reported in this city during the past five years.

Cornell University Medical College is now established in its new building in First avenue, between Twenty-seventh and Twenty-eighth streets. The building is still unfinished, but will be ready by the time for opening of term, October 2. Thus far more than twice as many students have registered as had registered in the corresponding period of 1899.

A famous surgical case was that in which, twenty years ago, Dr. Lewis A. Sayre and the late Dr. Thomas Sabine removed a tuberculous and ulcerated nose, and built up an artificial nose from the middle finger of a man's hand. At the time of the first operation most of the physicians believed that the man was dying from tuberculosis, but he survived and eventually left the hospital with his queer substitute nose. He has recently turned up again at the hospital with advanced Bright's disease, and refuses to believe that physicians of the present day are powerless to help him again cheat death.

NORTH CAROLINA.

Dr. G. M. Van Poole, of Spencer, who was recently appointed an acting assistant-surgeon in the army, has sailed from San Francisco for Manila.

The Clarence Barker Memorial Hospital at Biltmore, which was erected by the sisters of Clarence Barker, is to have an endowment fund; it has been started by his cousin, George W. Vanderbilt. The hospital was formally opened on September 4.

A sanatorium for invalids of moderate means is to be established at Asheville. Several years ago Mrs. M. Franklin Mallory, of Vermont, went to Asheville, and was impressed with the advantages of the locality for consumptives and with the impossibility of any except the wealthy availing themselves of these advantages under the existing condition. She therefore started a small establishment at which those of moderate means could live at small expense. The project proved so successful that she has purchased a large tract of land, has erected some buildings and will erect others which will be ready before cold weather. She has interested many Eastern and Chicago people in her work, and has already collected more than $4000 for the equipment of the home.

OHIO.

Dr. David R. Schall, of Del Roy, has located near East Liverpool.

Dr. Henry A. Furniss, of Galena, has opened an office at Constantia.

Dr. Ephriam W. Love, of Fayetteville, lost his residence by fire on August 30.

Dr. James E. Murray, of Middletown, has sold his practice to Dr. L. S. Krauss, of West Carrollton.

The late Dr. David B. Chamberlain, of Toledo, who died intestate, left an estate valued at $7200.

Dr. C. F. Clark, of Columbus, has just returned from his vacation in Canada.

Drs. Edwin H. and Allen M. Chilcote have sold their practice at Bloomdale to Drs. Rolla R. and John M. Adams.

Dr. U. S. G. Deaton, of Thackery, has received an appointment as acting assistant-surgeon in the army and has started for the Orient.

Dr. John A. Wilkins, of Delta, was made surgeon-general of the Grand Army of the Republic at its recent encampment in Chicago.

Dr. Samuel C. Lindsay, of Salineville, has been appointed acting assistant-surgeon in the army and ordered to report at San Francisco for assignment to duty.

Drs. George C. Skinner and John Francis, of Hamilton, sailed for Europe on September 5. Dr. Mark Millikin will have charge of Dr. Skinner's practice in his absence.

Dr. Clarence E. Drake, whose term as house physician at Zanesville Hospital expired on September 1, has been succeeded by Dr. Charles N. Hanna. The latter's position as physician at the Muskingum county infirmary will be assumed by the former.

An attempt was made to assassinate Dr. J. V. Cleaver, of Akron, August 30. Six shots were fired at him, fortunately without effect. He has been very outspoken in his remarks against the rioters, and it is thought that some revengeful rioter may be responsible for the attempt.

Dr. William J. Means, of Columbus, considers that his reputation has been injured to the extent of $25,000 and has brought suit against the *Citizen* Publishing Company for that amount. The casus belli is that the defendant journal stated that Dr. Mean's "mania for operating" might cause the death of Ray Chalfant, operated on at the Protestant Hospital.

OREGON.

Dr. D. J. McFaul, of Heppner, has concluded to locate at Pendleton.

Dr. Rupert J. Chipman has moved from La Grande to a larger field of labor in Portland.

Good Samaritan Hospital, Portland, suffered slight loss from fire, September 5. For a time there was apparently great danger, but thanks to the discipline and resolution of the nurses and attendants, the patients were all removed to places of safety.

The health report of Portland for August makes an excellent showing. No smallpox has been discovered for three weeks, and the pest-house is empty. Six cases of typhoid fever, and these isolated, are the only cases of contagious disease in the city.

PENNSYLVANIA.

Dysentery in virulent form is prevalent in Yocumtown and vicinity. All measures have been instituted to prevent it from spreading, but so far without result. All the local physicians have been taxed to the utmost to give relief to the sick. The disease is said to attack both old and young alike. So far seventeen deaths have occurred.

Dr. Fred A. Utley, of Carbondale, will locate for practice in Blossburg.

Dr. Hermanus L. Baer was married to Miss Mabel McKinley, niece of the President, at Somerset, on September 12. Dr. Baer is a graduate of the Jefferson Medical College, Philadelphia, of the class of 1900.

Meadville City Hospital is to have an addition built to accommodate patients suffering from contagious and infectious diseases.

Dr. Thomas A. Miller, assistant physician at Allegheny County Home, Carnegie, returned to Bellevue, September 1, on the expiration of his term of office.

Titusville is to have a hospital, through the generosity of David McKelvey, who donated the ground and several thousand dollars in cash. The building will cost $15,000.

Smallpox, which has prevailed at Erie for some time past, has assumed a more virulent type. All the schools have been ordered closed. So far, one death has been reported.

Philadelphia.

Drs. S. Louis Ziegler and G. E. DeSchweinitz have returned from Europe.

Dr. John H. W. Chestnut, who died a short time ago in Alaska, left an estate of more than a quarter of a million dollars.

During the past week the number of persons who enjoyed the public baths was the largest in the history of the institution, there being 418,958 visitors; of this number 100,939 were men, 309,550 boys, 6421 girls and 1639 women.

The trials of those accused of violating the pure food and oleomargarin law were held in quarter sessions' court beginning September 1. The indictments for violation of the oleomargarin law numbered 18, and 53 were on trial for selling adulterated food.

The Free Hospital for Poor Consumptives, in its second annual report, shows that during the year 124 cases were cared for, mostly at St. Agnes' St. Mary's and Rush hospitals. The receipts for the year were $9724.65, and the disbursements, $6748.34, of which $6118.54 was paid institutions for the board of patients.

The new children's hospital of Germantown was dedicated with appropriate ceremonies on Monday, September 3. Mayor Ashbridge delivered the dedicatory address. The dispensary of this institution was opened in June, and so far has treated 800 persons. At present there is accommodation for 25 persons, but it is hoped to double the capacity at an early date. The staff of physicians includes Dr. Ammon A. Apple, Dr. Charles K. Rowe, Dr. Marmaduke F. Van Buren, Dr. S. A. Cadwallader and Dr. Alexander Frazier.

Considerable discussion has ensued between the members of the board of health, the post-office authorities and the physicians in attendance on the child who died of diphtheria last week and whose body lay exposed in a parlor for several hours. It was first believed that the physician was to blame for not promptly reporting the case and he was censured by the board. It now develops that the physician in question gave the letter to the mail-carrier, so that it would appear he should be absolved from blame. This throws the cause for delay on the post-office authorities.

The Dairy and Food Commission of Pennsylvania have instituted suit against the firm of Burns, Metzger & Co., spice manufacturers, on the charge of adulterating cinnamon, starches and other articles. Thirteen charges will be presented at the hearing. The articles that have been subjected to chemical analysis are said to show considerable adulteration, such as cayenne pepper, 25 per cent. adulteration, with husks or mustard seed; cloves, 20 per cent. adulteration; white pepper, 7 to 8 per cent.; African cayenne pepper, 12 per cent.; plain black pepper, 17 to 20 per cent., and 12 per cent. adulteration of cinnamon. This firm has a plant valued at $100,000 and their goods are handled by many of the smaller dealers of the city. It is believed that warrants will be issued for other dealers in these products.

SOUTH DAKOTA.

Dr. Carl Laason, recently from Norway, has opened an office in Hetland.

Dr. E. W. Dickenson, of Webster, has bought the practice of Dr. John J. Fanset, of Millbank, and will succeed him.

Dr. Herman H. Hanstein has succeeded Dr. Bufort D. Black as resident physician at Homestake Hospital, Lead. Dr. Hanstein has been practicing in Kenosha, Wis. Dr. Black will leave for Mexico in a few days.

TENNESSEE.

Drs. E. D. Mitchell, L. L. Meyer and Marcus Haase have been elected to vacancies on the staff of the Memphis City Hospital.

Dr. Walter F. Rochelle, of Jackson, has purchased the interests of his partner, Dr. John T. Warford, in the Rochelle-Warford Sanitarium, and will conduct the establishment in future.

The suit for $500 against the Knoxville Traction Co., brought by Dr. Alfred S. Horsley for injuries to his wife and the destruction of his buggy, has been decided in favor of the defendant company.

An amendment to the Memphis Board of Health ordinance was recently offered by the mayor and passed on its first reading without objection, which makes it compulsory on physicians to report to the department of health any cases of typhoid fever or tuberculosis seen by them in practice, as the law now requires in smallpox and scarlet fever. It also provides that violation of this law shall be considered a misdemeanor.

The Memphis Medical Society at its last regular meeting adopted a resolution that the president of the society appoint a committee of three whose duty it shall be to correspond with other medical societies of the state with a view to securing unanimity in an effort to have an amendment to the state medical practice act adopted at the last meeting of the general assembly, rescinded at the next meeting of this body. The amendment referred to exempts graduates of the medical schools of Tennessee from examination before the State [illegible] rd of Medical Examiners, to which graduates [illegible] must submit before they are granted [illegible] state.

TEXAS.

A new medical practice act has been approved by the State Medical Association, which provides for three separate boards of medical examiners, from the three principal schools of medicine, no member of any of which shall be a member of the teaching force of any medical school.

The reports of the ravages of the sea and storm in Galveston are as yet only vague, but it is reported that among the buildings destroyed are the John Sealey hospital, with most of the patients killed; Orphans' Home, casualties unknown, and St. Mary's Infirmary, only eight saved. The capacity of the John Sealey Hospital was 125 beds, and that of St. Mary's Infirmary, 350 beds.

UTAH.

Dr. Chauncy M. Benedict, of Salt Lake City, has been commissioned major and surgeon in the National Guard of the state.

The report of the Salt Lake City Board of Health for the week ended September 1, shows 23 births and 16 deaths. Seven cases of scarlatina, four cases of smallpox and two cases of typhoid fever were reported during the week.

VIRGINIA.

Dr. Hamilton P. Howard, of Alexandria, has been appointed surgeon at the Virginia Military Institute at Lexington.

Dr. Benjamin Harrison, of Richmond, surgeon of the state penitentiary, is seriously ill with typhoid fever in Clarke county. Dr. James P. Roy is acting as *locum tenens* during his illness.

WASHINGTON.

The Everett Hospital is so crowded that it is obliged to turn away patients.

Dr. Millard G. Hinkle has removed to Seattle from Stockton, Cal.

The city health officer of Everett, Dr. John R. Hathaway, claims that diphtheria is entirely stamped out. No new cases have been reported for a week, all who had the disease have recovered and quarantine has been raised.

WISCONSIN.

Dr. Eugene R. Herring, of Manawa, has removed to Shell Lake.

Dr. Gilbert E. Seaman has returned from the Philippines, resigned from the army, and resumed practice in Milwaukee.

Dr. John Hund, who has practiced medicine and conducted a German paper in Athens for several years, has moved practice and paper to Marathon City, where he has entered into partnership with Dr. P. J. Taugher.

Dr. Frank C. Studley, of Milwaukee, has leased a six-acre tract of land on the upper Milwaukee river, for a sanatorium. The buildings now on the ground will be remodeled and enlarged and will be ready for use October 1.

An outbreak of typhoid fever, mild in character, is reported in the northwestern part of Milwaukee. Twenty cases have occurred, and two-thirds of these were reported in one day. The health department is endeavoring to ascertain the source of infection.

CANADA.

Dr. Morrison, a graduate of Queen's, Kingston, has been appointed house surgeon of the New York Polyclinic Hospital.

Dr. Haig, of Campbellford, has been appointed superintendent of the Kingston General Hospital, and will begin his duties on October 1.

Montreal is going ahead with its crematory. Arrangements have been made to accept Sir W. C. Macdonald's offer to build and endow the institution.

Dr. Gillis, medical superintendent of the Brandon Asylum for the past four years, will be removed from that office by the Macdonald government of Manitoba.

Dr. Lamont, Winnipeg, has returned to that city after finishing a trip of 2000 miles of Indian medical inspection on the Saskatchewan river and lakes Winnipeg, Manitou and Winnepegosis.

The province of Quebec is now practically free from smallpox. The last case was disposed of about a month ago. A few cases of scarlet fever still exist, but they are well under control.

Dr. E. Prose, late of the Manitoba Medical College, writes from Cape Town, August 1, saying that Dr. A. B. Bing, a fellow-graduate in the same contingent, had died of enteric fever at Johannesburg.

Dr. A. J. Douglas has been selected for the position of health officer for Winnipeg. The former inspector, Dr. Inglis, severed his connection with the department as a result of the recent smallpox controversy.

The New Brunswick Medical Society held its annual meeting at St. John on July 17; the following officers were elected; President, Dr. G. T. Smith, Monckton; vice-president, Dr. S. C. Murray, Albert; treasurer, Dr. G. G. Melvin, St. John; secretary, Dr. J. H. Scammell, St. John.

TO PREVENT CONSUMPTION.

The first annual meeting of the Ontario Association for the Prevention of Consumption convened in the City Hall, Toronto, on September 4, under the presidency of Dr. James Thorburn of that city. The draft constitution was submitted to the meeting and adopted. It defines the objects of the Association to be the collection and dissemination of information as to the contagious character of tuberculosis, and as to the methods and measures necessary for public protection; the education of public opinion; to encourage co-operation of governments, municipalities and philanthropic institutions to provide sanitoria. The fee for ordinary members was placed at $1. Provision was also made for the formation of branch associations on condition that they transmit to the treasurer one-fifth of the sums received as membership fees. Dr. James Thorburn was re-elected president and Dr. P. H. Bryce corresponding secretary.

CIVIC HEALTH REPORT, MONTREAL.

The annual report of the civic health department has been printed for 1899 and embraces a pamphlet of 132 pages. The total number of deaths during the year was 6871, including 692 illegitimate children and premature births, making a proportion of 24.51 per 1000 of the population. This is an increase of 3.85 per thousand of the population, including 1.86 per 1000 due to illegitimates and premature births over 1898. The total number of illegitimate births was 522. There were still remaining on Dec. 31, 1899, 4913 privy pits in Montreal as against 8891 in 1891. In the civic hospital for contagious diseases, 359 patients were treated, 217 for diphtheria, and 140 for scarlet fever and two for measles. Of the total number 151 were children under five years of age. The death-rate was 9.41 per cent. Over 1500 examinations were made in the bacteriological laboratory by Dr. J. E. Laberge, who is in charge of this department. The total appropriation for the department was $117,383 and the outlay $114,929. Dr. Nolin vaccinated 962 people, Dr. Daze 480 and Dr. Coyle 238, making a total of 1772. There were 1878 cases of contagious diseases in the city during 1899, made up as follows: Diphtheria, 678; diphtheric croup, 54; croup, 35; scarlatina, 568; typhoid fever, 260; measles, 270; varioloid, 18. Of these cases 706 were children under five years of age. The births numbered 9655. The birth-rate was 48.45 amongst French-Canadians, 20.81 amongst other Catholics and 22.29 amongst Protestants. The surplus of births over deaths was 2784.

MARINE-HOSPITAL NOTES.

LUSTIG'S SERUM.

In a report to the surgeon-general, U. S. Marine-Hospital Service, Dr. Geddings refers as follows to Lustig's serum, reference to which is occasionally made in the medical journals. Lustig's serum is for the prevention and cure of plague and is the serum of a horse immunized by toxins of plague precipitated after a particular method. Lustig and Galeotti have demonstrated that the toxins of plague belong to the class of nucleins and they prepare it by subjecting cultures of the bacillus pestis to the action of a 0.6 per cent. solution of caustic soda or potash. In three or fours days the bacilli are entirely dissolved and the nucleins set free are precipitated as usual by acetic acid. The substance is then collected and used for the immunization of horses, it being necessary to use a weak alkali, as sodium carbonate, for their solution. The toxin thus precipitated has about the same strength as ordinary plague toxins precipitated by ammonium sulphate. An effort was made in the Hygienic Laboratory to make practical use of this method, but it was found impracticable, owing to the very small quantity of product obtained by following the method as described by Lustig. The serum of a horse immunized with this toxin would probably have about the same antitoxic or curative value as a serum prepared by the ordinary methods, neither more nor less.

WHAT WAS DONE BY CONGRESS AT ITS LAST SESSION FOR THE MARINE-HOSPITAL SERVICE.

The continued growth of the Marine-Hospital Service, and the extension of its duties to Cuba, Porto Rico and the Philippines, made it necessary for Congress to be liberal in meeting the demands of the Service as explained to it by the surgeon-general. The office force of the bureau at Washington was increased by the addition of five new clerks, making a total of twenty-two clerks distributed among the seven divisions of the office under its reorganization. All these divisions are under medical officers, excepting one, and are as follows: 1, Division of marine-hospitals; 2, division of domestic quarantine; 3, division of insular and foreign quarantine; 4, division of sanitary reports and statistics; 5, division of personnel and accounts; 6, miscellaneous division, and 7, chief clerk. The hygienic laboratory, although not a part of the surgeon-general's office proper, is located in the same building, and the director is available for conference on many matters relating to scientific determination regarding infection and disinfection. For the Marine-Hospital Service, proper, Congress appropriated $8000 for a new surgeon's residence at San Francisco, and $16,000 for completion of pavilion yards at the marine hospitals at Boston, Cleveland, Detroit, Mobile and St. Louis, and made the general fund available for repairs and improvements. For extending and improving the national quarantine stations the sum of $359,050 was appropriated, including $131,000 for the San Francisco quarantine, $125,000 for the Florida quarantine stations—made necessary by the transfer of Tortugas to the navy department for a coaling station—$30,000 for the Savannah station, $23,750 for San Diego, $8000 for the Reedy Island, Delaware River, station, and smaller sums for the other quarantine stations at Delaware Breakwater, Cape Charles, Virginia; Brunswick, Georgia; Gulf quarantine, Ship Island, Miss., and South Atlantic quarantine Blackbeard Island, Ga. For the annual running expenses of the national quarantine stations, including those in Porto Rico, the sum of $235,000 was appropriated. Laws were passed placing the whole of the quarantine service of Porto Rico and of the Hawaiian Islands under the Marine-Hospital Service and appropriating $75,000 for the maintenance of the quarantine service in Hawaii. For the fund for the prevention of the introduction or spread of cholera, yellow fever, smallpox and plague, known as the epidemic fund, $500,000 was appropriated. The Marine-Hospital Sanatorium for the treatment of tuberculous patients of the service received the sanction of Congress after the whole scheme had been laid before a committee of the Senate, by being included in one of the appropriation bills for public buildings. A bill to increase the efficiency of the National Quarantine Service, providing penalties for infraction of the national quarantine laws, etc., passed the Senate and was reported on favorably in the House of Representatives, and will doubtless pass at the next session, there being no objection to it.

PLAGUE SITUATION IN GLASGOW, SCOTLAND.

In continuation of the same subject in issue of September 8, 1900: P. A. Surgeon A. R. Thomas, of the United States Marine-Hospital Service, now in Glasgow, reports, on September 7: "No new cases for three days. Conditions good." He has been directed to classify the freight leaving Glasgow, certain articles to be passed without inspection, other articles to be inspected and passed on a certificate showing non-infected origin, a third class to be entirely passed after disinfection, and a fourth class to be entirely debarred. Asst.-Surgeon John F. Anderson, after arriving in London, was ordered to Liverpool to carry out the same instructions as were issued to Dr. Thomas with regard to passengers and freight coming from Glasgow for shipment at Liverpool. Arrangements are being made for the ship's surgeons on transatlantic lines while plague prevails in Glasgow to take the temperature of all steerage passengers and crew the day before arrival in the United States for the information of the quarantine officer at the port of arrival. The Canadian government has requested that Dr. Thomas inspect all vessels leaving Glasgow for Canadian ports, until the arrival of their own representative in Glasgow, and this request has been granted. On September 1, the surgeon-general detailed an officer to confer with the quarantine officer of New York, as to the measures he was taking or proposed to take other than those laid down in treasury regulations, New York being the most important port in the United States having commerce with Glasgow. At a subsequent conference with Health Officer Doty at the bureau in Washington, it was agreed that he would continue what he had already begun; viz.; the taking of temperatures of all the steerage passengers and crew of transatlantic liners from Glasgow and other ports whence Glasgow passengers might take passage to the United States, and setting aside for further examination all persons who show any rise in temperature, such persons being submitted to glandular examination, as well as observation for a period of time. Orders were issued to all officers of the Marine-Hospital Service on quarantine duty and requests to all state and local health officers at ports where there is passenger traffic, to put in effect the same practice. The taking of temperatures as part of the ordinary inspection of vessels arriving at quarantine is now considered a very essential feature in quarantine administration. Mild cases of almost any infectious disease can "brace up" for the ordinary quarantine inspection and pass it, but this cannot be done if the temperatures are taken. The New York quarantine has been employing this practice for some time with regard to passengers from Habana, and the surgeon-general of the Marine-Hospital Service has instructed his officers at National quarantine stations to the same effect.

Correspondence.

Dr. Jacobi's Address and "Sectionalism."

New York City, Sept. 10, 1900.

To the Editor:—As a reply to the criticisms on some remarks delivered by me before the Thirteenth International Medical Congress, August 6, permit me to say to Dr. J. Wilkinson Jervey[1] that nothing is further from me than to harbor or try to create any sectional feelings. I deplore to have given him any such impression. The Doctor says himself that, "It is not the actual expression to which the Doctor gave tongue that is objectionable, but the inferential and insinuating quality of his remarks addressed to those good people across the water who know us not, save as existing, and who quite naturally accept the imputations and inferences." In this fear, Mr. Editor, I am happy to say, the Doctor is mistaken, and I feel sure he will be pleased to learn, in spite of his objections to some—shall I say unguarded?—expressions of mine, and your readers will learn with satisfaction, that not only was my address applauded by the Americans present, but that, from Lannelongue and Virchow down, the whole audience felt and appreciated (and expressed their appreciation) the claims of American medicine and medical men to recognition as full equals in the co-operative struggles of our international science and art. When I had finished, and ever since, I had the impression that I had simply continued in my life-long efforts to improve the estimation in which the American profession was held in Europe—both as a trifling proof of my gratitude for the endless acts of kindness bestowed on me personally by that profession, and as a demand of testimonial justice. Sad if I should have made a grievous mistake. But allow me to say that such references as I have been able to see in the medical and the lay press of Europe, justify that belief of mine. Besides, I refer you to the concluding paragraph, and to many others, of my address, as my defense—if defense there must be after my fellowship of nearly half a century in the profession, and after forty years of teaching and of other public work.

---

[1] The Journal, p. 638.

In your editorial remarks[2] you "regret the semi-apologetic accent of some portions of the address in regard to our national standing in medicine and science. Foreigners are condescending enough at present, and we naturally prefer such an utterance as that of Osler, who saw in the future of America a scientific Mecca, rather than even an equivocal admission of real or fancied national defects, in such an address." I think you refer to his address on the importance of post-graduate study, in which he says: "To students who wish to have the best that the world offers, let me suggest that the lines of intellectual progress are veering strongly to the West, and I predict that in the twentieth century the young English physicians will find their keenest inspiration in the land of the setting sun." In my address I say, "The time is fast approaching, I hope, when your students and doctors will travel with the sun to enjoy the light of the West." That does not exactly look like a "timid presentation" of our claims. And again, "There was a period when they asked: Who reads an American book? American books are now read the world over by privileged men, and even translated. Verily, verily, the time should come speedily when they will ask: Where is the ignoramus that does not know American literature?" Such are my convictions on that point, and I have quietly tried to turn the "condescension"—so that you call it—of European public opinion in different ways these forty years.

Lately, I received many letters remonstrating with one or the other view expressed in my address. Let it be understood that I pronounce my own opinions when I am speaking publicly; that the meeting before which I appeared was international, not national or European only, and finally that I can not enter into personal correspondence, or replies, or as a daily newspaper has it, "quarrels." But I may be permitted to say —I am referring to some opinions as expressed in my address, and criticised—on behalf of those who will not or can not read the address in full; that I am still of the opinion that we should study the Pharmacopeia of the United States and the formulary of the American Pharmaceutical Association more than the price-lists of the wholesale druggists, whom we allow to do part of our thinking; that we can find better employment than in discussions with their and publishers' agents; also that our 156 medical schools should be reduced to 25 and attached to a university and furnished hospitals of their own, and our 200 or 300 medical, or alleged medical, journals to 50; that those which are founded by professional men or by the profession at large, are preferable for many reasons, to those published in the interests of a publisher, a manufacturer or of a proprietary medicine owner; also that syndicates of medical men should see to the production and consumption of medical literature. I am still of the same opinion that I expressed in my address in regard to consultations with sectarians; and I still hold the same political views that I was rebuked for in an anonymous letter. Finally, I am still of the opinion that we should participate, not as sanitarians only, in the political and municipal affairs. Let me thank you, Mr. Editor, for the courtesy you extended me in opening your journal to these lines. Very respectfully yours, A. JACOBI, M.D.

---

[2] See p. 628.

A CIRCUS traveling through the province of Quebec, Canada, introduced the name of Dr. Sabourin, of Saint-Jean, into a song on the program. The doctor sued the company for $5000 and was awarded $500 by the local courts, the *Revue Méd.* reports.

Book Notices.

THE MEDICAL DIRECTORY OF NEW YORK, NEW JERSEY AND CONNECTICUT. Price, $2.50. New York: The New York State Medical Association (Dr. Ogden C. Ludlow, secretary, 2309 Seventh avenue). 1900.

The Directory of the physicians of New York, New Jersey and Connecticut is a good illustration of what a state society can do to benefit its members and the profession, without depending upon commercial enterprise outside of its ranks. This directory bears evidence of being gotten up with the idea of giving all the information possible, so that it may be valuable to its possessor, rather than to make it a profitable commercial enterprise. The first page of the directory, on which is commenced a Street List of Physicians of Manhattan and Bronx, indicates this. It may not be often that one desires to know what physicians live on a certain street, but sometimes this information is decidedly important. The street index is given for all the large cities and boroughs. Following the street list is a list of physicians of Manhattan and Bronx, arranged alphabetically. Besides the address, there is also given the college and year of graduation, office hours, positions held, and to what society or societies each is affiliated. The list of Brooklyn physicians is printed on a different colored paper, to facilitate easy and quick reference—a most excellent idea. Following that of Brooklyn is a list of the physicians of the boroughs of Queens and Richmond. After this comes a vast amount of information about matters medical in Greater New York, such as the department of Public charities, of corrections, etc.; the various courts of justice and the civil boards; ordinances relating to physicians, midwives, etc.; list of hospitals, dispensaries, etc.; list of the various medical societies of Greater New York, with their officers, time and place of meeting, etc., and a list of registered pharmacists. The same general information is also given regarding other large cities in the three states covered. The homeopaths and eclectic physicians are listed separately, the name and address only being given. The whole makes a book of great value, especially to the physicians of the states it includes, and too much praise can not be bestowed on the committee for the successful way in which they have accomplished their task. The amount of labor it entailed can be appreciated only by those who have attempted such work. Every physician in New York, New Jersey and Connecticut should obtain a copy of the book, not only for its intrinsic value, but to encourage such an enterprise on the part of physicians.

FRACTURES. By Carl Beck, M.D., visiting surgeon to St. Mark's Hospital; to the New York German Poliklinik, etc. With an appendix on The Practical Use of the Röntgen Rays. 178 illustrations. Price, $3.50. Philadelphia: W. B. Saunders & Co. 1900.

In the introduction to his book, the author, after giving a brief historical description of the Röntgen rays, calls attention to their great value in the management of fractures, and mentions those in which the use of the rays is especially valuable as a diagnostic measure. By their use accuracy takes the place of ignorance and doubt, and painful manipulations cease to be necessary for diagnostic purposes. In Part I, is considered the classification of fractures, and the general process of repair and treatment. In Part II, is taken up in detail the management of the special fractures. The author's method of presenting the subject is simple, practical and easy of comprehension. There is a liberal supply of illustrations to graphically assist the reader in a thorough understanding of the text. The common, and many of the rare fractures, are represented skiagraphically. Practically all of the illustrations are new.

If the author had given as a subtitle "A Plea for the More General Use of the Röntgen Rays in the Diagnosis and Treatment of Fractures" it would have better described the character of his book. The preface reads as though the book was devoted to the Röntgen rays; the introduction is on the use of the rays, and an appendix of over fifty pages is on the practical use of the Röntgen rays. The latter, by the way, gives much valuable information in regard to the kind of battery to use, and its management. The author is evidently an enthusiastic believer in the great value of the X-rays, even in its present development. His enthusiasm convinces him that "exploratory laparotomy for suspected lithiasis will hardly be necessary any more," a conclusion which all surgeons are not yet ready to endorse. The author is not too enthusiastic, however, and his book can not but do good in extending the use of the Röntgen rays in the management of fractures.

Deaths and Obituaries.

Jacob M. DaCosta, M.D., died at his residence at Villa Nova, near Philadelphia, from heart disease, September 11, at the age of 67 years. He was born in the Island of St. Thomas, West Indies, received his literary and classical education in Germany and then began his medical studies at the Jefferson Medical College, Philadelphia, his preceptor being Professor Mütter. He was graduated in 1852, and after spending two years in the hospitals and medical schools of Paris and Vienna, he returned to Philadelphia and established himself in practice, devoting himself especially to diseases of the heart and lungs. His contributions to medical literature have been large and varied, many of his works, such as "Medical Diagnosis," being standard. He was for some time attending physician at the Episcopal Hospital and later at the Philadelphia and Pennsylvania hospitals. In 1864 he was appointed lecturer on clinical medicine at his alma mater, and eight years later was chosen to fill the chair of theory and practice of medicine in that institution. In 1895 he was made president of the Philadelphia College of Physicians. At the time of his death he was professor emeritus in Jefferson Medical College and a trustee of the University of Pennsylvania.

William S. Ward, M.D., a graduate of the College of Physicians and Surgeons, New York, in the class of 1849, died at Newark, N. J., September 1, at the age of 79. He had practiced medicine in Newark for more than fifty years. During the Civil War he was stationed at the Ward General Hospital, Newark, and there achieved a reputation for administrative ability. He served on the staff of St. Michael's and St. Barnabas' Hospitals and was attending physician at the Protestant Foster Home for more than thirty years.

Henry D'Huy, M.D., died at his home in Kansas City, August 28, at the age of 80 years. He was born in Hanover, studied medicine in Dresden and at the University of Leipsic. He was graduated in 1843, and came to America in the same year, locating in Newburg, N. Y. In 1856 he located in Winterset, Ia., where he practiced until the outbreak of the Civil War, through which he served, first as a private, then as acting assistant-surgeon. He moved to Kansas City in 1889.

Josiah S. Bowen, M.D., died at Mt. Washington, Md., on August 29, of heart disease, aged 68 years. In 1854 he went with a party of gold seekers to California, and later studied medicine in the University of Maryland, where he graduated in the class of 1864. He located at Mt. Washington, and practiced there nearly forty years.

Frank Stephen Milbury, M.D., a graduate of the Cincinnati College of Medicine and Surgery, in the class of 1888, died in his 44th year at his home in Brooklyn, N. Y., August 29. He was born in New Brunswick, became a dentist and practiced in Nova Scotia, and afterward in Mexico. He then took an extended post-graduate course in Europe and established himself in Brooklyn. At the time of his death he was a member of the American Medical Association and several other societies, besides being identified with Bedford Hospital and New York Eye and Ear Infirmary.

Jeremiah P. Eggman, M. D., died at Mullanphy Hospital, St. Louis, Mo., from the effects of heat exhaustion, August 25, at the age of 31 years. He was a native of St. Louis, graduated in pharmacy, then entered the medical department of Washington University and was graduated in 1892. He practiced until the outbreak of the Spanish-American war, when he went to the front with the 1st Missouri Infantry, U. S. V. At the termination of the war he resumed practice in St. Louis.

Easton Burchard, M.D., a graduate of the Kentucky School of Medicine, Louisville, 1889, assistant-surgeon U. S. Army, died of dysentery on September 2 aboard the transport *Grant* at Nagasaki. He was a native of Osage County, Missouri, and was a resident practitioner of Kansas City. He received his appointment as first lieutenant and assistant-surgeon, 40th Volunteer Infantry, August 17, 1899, and in October of that year embarked with his regiment for the Philippines.

D. V. Dean, M.D., died September 3 in the City Insane Asylum, St. Louis, at the age of 70 years. From 1876 till 1886 he was superintendent of the City Hospital. He was one of the pioneer bacteriologists of the West and served as a trustee and as professor of physiology in Beaumont Medical College. In 1896 evidences of mental disease became noticeable and in December of that year he was committed to the insane asylum.

J. Travis Taylor, M.D., a graduate of University College of Medicine, Richmond, Va., in the class of 1896, died in that city after an operation for appendicitis, August 31, at the age of 26 years. The Richmond Academy of Medicine held a largely attended special meeting September 1 and passed resolutions of sorrow and regret over the early death of so promising a member of the fraternity.

Joseph E. Traynor, M.D., who was graduated from the medical department of the University of Pennsylvania in 1900, and afterward passed the examination of the State Medical Examining Board of Delaware, died August 28 at Wilmington, Del., from consumption, after a long illness, at the age of 23 years.

William O. McDowell, M.D., died at Scotland Neck, N. C., August 15, at the age of 43 years. He was graduated from the University of Pennsylvania in 1876 and commenced practice in Union, but moved to Scotland Neck a few months later, and there practiced until 1895, when his health became impaired.

John G. Mennie, M.D., for many years well known as a practitioner of medicine in Toronto, Ontario, died at his father's residence in Fergus, August 24, after a long illness, from Bright's disease. He was born in 1854, and was graduated by the medical faculty, University of Toronto, in 1882.

Edwin H. Amoss, M.D., of St. Paul, Minn., was found by a policeman in a stupor, due to intoxicants or drugs, to the use of which he was addicted, and died in the City Hospital, August 27. He was a graduate of the University of Michigan medical department, in the class of 1884.

Joshua A. Gore, M.D., was found dead on a sandbar in the Missouri River at St. Joseph, Mo., September 1. It is supposed that he committed suicide. He was born in 1826, had lived in St. Joseph since 1861, and was one of the oldest practitioners in that city.

John K. McLeod, M.D., died at his residence in Moss Point, Miss., August 29, aged 60 years. He was a graduate of the medical department of Tulane University, New Orleans, La., in 1868, and had practiced for more than thirty years in Moss Point.

Henry B. Rupp, M.D., died at Hummelstown, Pa., August 27, at the age of 64 years. He was graduated from the department of medicine of the University of Pennsylvania in 1861, but retired from practice on account of ill-health, in 1885.

Richard I. Duckett, M.D., died suddenly of heart disease at Bakersville, Md., August 31, aged 56 years. He was graduated from the University of Maryland in 1866, and had practiced in Bakersville for twenty years.

Thomas H. Buck, M.D., of Leetown, W. Va., died suddenly from apoplexy, at Luray, Va., August 29, at the age of 76 years. He was a graduate of the University of Louisville medical department, in the class of 1848.

Thomas E. Evins, M.D., major and surgeon 49th U. S. Volunteer Infantry, died from fever in the Philippine Islands. He formerly resided in Birmingham, Ala.

Miscellany.

The Pasteur Institute of India was opened August 9 at Kasauli. Previous to that soldiers bitten by dogs were sent to Paris for treatment.

Famine in India.—There are over 6,250,000 people in receipt of relief. According to the *Lancet*, 3,500,000 are on relief works, and the remainder are receiving gratuitous relief.

Copies of The Journal Wanted.—The following numbers of The Journal are wanted to complete volumes for a member: Vol I., Nos. 1 and 16; Vol. II., No. 14; Vol. III., Nos. 4, 11, 25. Twenty-five cents each will be paid for these at the office of The Journal.

Sanatoria for Contagious Diseases Not Allowed.—A wealthy young woman, Mdlle. Noualheir, has established a refuge for incurables at Limoges. She makes periodical visits to Paris to collect inmates and brings twenty at a time, usually persons in advanced stages of consumption. The *Gaz. Méd. de Paris* states that the local authorities have found that tuberculosis has doubled in the vicinity of her refuge and have taken measures to close it and prohibit the maintenance of any sanatorium for contagious or epidemic diseases, public or private, inside the city limits.

Societies.

Coming Meetings.

American Association of Obstetricians and Gynecologists, Louisville, Ky., Sept. 18-20.

Medical Society of the State of Pennsylvania, Wilkesbarre, Sept. 18-20.

Medical Society of the Missouri Valley, Council Bluffs, Ia., Sept. 20.

American Electro-Therapeutic Association, New York City, Sept. 25-27.

American Public Health Association, Indianapolis, Ind., Oct. 22-26.

Golden Belt Medical Society, Enterprise, Kan., Oct. 4.

Idaho State Medical Society, Boise, Oct. 4-5.

Utah State Medical Society, Salt Lake City, Oct. 4-5.

Wyoming State Medical Society, Cheyenne, Oct. 9-10.

Mississippi Valley Medical Association, Asheville, N. C., Oct. 9-11.

Iowa State Association of Railway Surgeons, Des Moines, Oct. 11-12.

Vermont State Medical Society, Rutland, Oct. 11-12.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, Tenn., Oct. 11-13.

New York State Medical Association, New York City, Oct. 16-18.

Medical Society of Virginia, Charlottesville, Oct. 23.

The Louisville Society of Medicine met at the Galt House on September 3 and elected the following officers: President. Dr. Edward Speidel; vice president, Dr. J. R. Morrison; secretary, D. W. O. Green, and treasurer, Dr. William Jenkins.

St. Joseph County (Ind.) Medical Society met in the office of Dr. Jacob W. Hill, South Bend, August 28, Dr. James A. Varier presiding. Cases were reported by Drs. Frank M. Sawyer, George W. Van Benschoten, Jacob W. Hill and Harry F. Mitchell.

Hampden County French Medical Society.—The Canadian physicians residing in the Holyoke district in Massachusetts have organized a society with the above title, to hold quarterly meetings at Springfield. H. E. Chaput, M.D., was appointed secretary.

The Perry County (Ind.) Medical Society held its regular monthly meeting at Tell City, September 4. Papers were read by Drs. F. Anson Evans and C. M. Brucker, of Tell City, on "Consumption," and a general discussion of the subject, by the members of the society, followed.

The Medical Society of City Hospital (St. Louis) Alumni met in the Board of Education rooms September 6. Dr. Given Campbell presented patients illustrating chorea and tabes dorsalis, and Dr. Clarence Loeb exhibited pathological specimens of aneurysm and arteriosclerosis.

The Polk County (Ia.) Medical Society held a meeting in the club rooms of the Kirkwood Hotel, Des Moines, September 4. Papers were read by Dr. Charles E. Currie, of Des Moines, on "The Therapeutics of Shock," and Dr. H. A. Minassian, of Des Moines, made a clinical report on herpes zoster.

The Ontario Anticonsumption League met at the city hall, Toronto, Ontario, on September 4. The officers of the league are: Sir Oliver Mowat, honorary president; James Thorburn, M.D.. president; P. H. Bryce, M.D., corresponding secretary; Rev. C. S. Evy, B.A., D.D., organizing secretary, and L. Brock, M.D., of Guelph, treasurer.

The Contra Costa County (Cal.) Medical Society held a meeting at Marinez, August 22. Dr. J. S. Riley, of Port Costa, president; Dr. J. T. Breneman, of Martinez, first vice-president; Drs. George Mackenzie and Francis F. Neff, of Concord, secretary and assistant-secretary; Dr. Jerome T. Gardner, of Brentwood, and Dr. Claude R. Leach, of Walnut Creek, were present. The president read a paper and Drs. Mackenzie and Leach presented specimens.

Tri-State Medical Society of Alabama, Georgia and Tennessee.—As the time of meeting of this society was the same as that selected by the Mississippi Valley Medical Association, the Tri-State Society has changed its date to October 11-13. A rate of one fare for the round trip will prevail at that time to the reunions of the Army of Cumberland and the Spanish-American War veterans. Tickets will go on sale Oct. 8 and will be good until Oct. 13.

The Reading (Pa.) Medical Association met in the Raser building, August 29. Dr. S. Banks Taylor read the address of the retiring president, John K. Seaman. The following officers were elected: Dr. Seymour T. Schmehl, president; Dr. John K. Seaman, first vice-president; Dr. S. Banks Taylor, second vice-president; Dr. Louis L. Thompson, secretary and curator; Dr. Oan J. Thompson, treasurer, and Dr. Abraham S. Randenbush, representative to the Reading Hospital.

The Mason County (Ky.) Medical Society met at Maysville, August 29, Dr. John A. Reed, of that city, being host. Dr. Smith read a paper on "Post-Partum Hemorrhage"; Dr. Thomas E. Pickett, of Maysville, one on "The Surgery of Placenta Previa, With Notes of Two Cases: An Effective Method of Meeting a Formidable Complication"; Dr. A. N. Ellis presented a case of traumatic iridectomy. The next meeting will be held at the office of Dr. Amos G. Browning, September 26.

The Belmont County (Ohio) Medical Society held its regular bi-monthly meeting, August 30, at the Windsor Hotel, Bellaire. Dr. D. L. Marsh reported a case of incipient caries of the spine; Dr. Dexter W. Boone, of Bellaire, one of traumatic tetanus, with operations, and Dr. Ellis C. Cope, of Barton, one of valvular disease of the heart. Dr. J. Park West, of Bellaire, made a report of the recent meeting of the American Pediatric Society, and Dr. Alexander H. Korner, of Woodsfield, read a paper on "Eye-Strain as a Factor in Epilepsy." The meeting was followed by a clinic.

The Kankakee Valley District Medical Society met at Hammond, Ind., September 11, under the presidency of Dr. I. B. Washburn, of Rensselaer, Ind. After the president's address, papers were read by Dr. George E. Hoffman, of Rochester, Ind., on "Internal Causation of Disease"; Dr. D. J. Loring, of Valparaiso, Ind., on "Inflammation and Its Treatment"; Dr. W. H. Thompson, of Winamac, Ind., on "Smallpox"; Dr. J. H. Hockins, of Whiting, Ind., on "Treatment of Burns," and Dr. George W. Van Benschoten, of South Bend, Ind., on "The Relation of the General Health to the Eye and Its Diseases."

American Academy of Railway Surgeons.—The seventh annual meeting of the academy was held in the State Senate Chamber, St. Paul, Minn., September 5 and 6, under the presidency of Dr. Charles A. Wheaton, of St. Paul. Fifteen papers were read and freely discussed. Twenty new fellows were elected. The officers for the ensuing year are: President, Dr. D. S. Fairchild, of Clinton, Ia.; first vice-president, Dr. W. L. Estes, of South Bethlehem, Pa.; second vice-president, Dr. W. J. Mayo, of Rochester, Minn.; secretary, treasurer and editor, Dr. T. B. Lacey, of Council Bluffs, Ia. Chicago was selected as the place for holding the next annual meeting, the date to be fixed by the executive board.

New York State Medical Association.

FIRST DISTRICT BRANCH.

President, Charles H. Glidden, M.D., Little Falls.

The annual meeting of this Branch Association was called to order by its president at the Butterfield House, Utica, on the afternoon of Sept. 4, 1900.

PURE MILK FOR CITIES AND VILLAGES.

DR. CHARLES H. GLIDDEN thought it would be feasible in small cities to have the milk brought to a central station, where, after having been pasteurized or sterilized, and properly bottled, it would be placed for distribution in the hands of men who had nothing whatever to do with stables. The milk should be delivered only by such persons, thus avoiding one common and serious source of contamination. All milk should be thoroughly and slowly aerated as soon as taken from the cow, and before cooling, and this process should be continued until all animal odor had been removed. It is best conducted in a cheap, well-ventilated building remote from the stables. The ceilings of the stables should be made of well-joined timber, and should be whitewashed at least twice a year. The venders of milk, in the opinion of the speaker, should not be interested at all in the dairies, the milk being bought outright.

DR. C. B. TEFFT, Utica, said that few subjects come before the physician that give so much trouble as the regulation of the dietary of the sick. He was coming to feel that milk is almost a poison to the average person. He was pretty well satisfied that a large proportion of the milk sold in Utica had some preservative in it, and he did not believe there was a gallon of milk in that city which did not give an acid reaction at the time it was delivered to the consumer. In certain sections of the country formaldehyde was very commonly employed as a preservative of the milk. There were many breweries in his section, and it was reasonable to suppose that the grain from these establishments was fed to the cows. The state law merely says that fermented articles must not be fed to cows, yet it was well known that although this grain is said to be given to the cattle before fermentation has occurred, it was commonly mixed with cornmeal and allowed to stand until bubbles of gas could be seen on the surface of the mixture at the time of feeding. This would seem, then, to be merely an evasion of the law.

DR. LEON T. LEWALD, New York City, said that more emphasis should be laid on the great importance of cleansing the udder of the cow and on having the milker's hands scrupulously clean. Clean milk, used within a few hours, was usually a safe food, there being, as a rule, only a few bacteria, and these generally harmless ones under these conditions. Just as in surgery one could succeed largely through asepsis as opposed to antisepsis, so in connection with the milk-supply it was possible to have a safe article of food if the necessary precautions to insure cleanliness were observed. At the present day one was able by the application of the tuberculin test to properly control tuberculous disease among cows.

PLAN FOR THE REORGANIZATION OF THE NEW YORK STATE MEDICAL ASSOCIATION.

DR. FREDERICK HOLME WIGGIN, of New York city, was present to explain the new scheme of reorganization of the association. He began by saying that physicians as a class had very little influence with politicians, public officials and laymen generally. This fact had been brought out with painful clearness in connection with the efforts that had been made to regulate the abuse of medical charity. Physicians had so long stood alone and been weak-kneed that patients, when pressed to pay for professional services rendered, would quickly turn and threaten suit for malpractice if the matter were pressed further. It was most unfortunate that many physicians, feeling their individual weakness, had been weak enough to make all sorts of compromise settlements in such suits, with far-reaching and disastrous results to their professional brethren. These facts show the need for better organization, and, hence, the movement to reorganize the New York State Medical Association. All must see, Dr. Wiggin said, the necessity for effective organization, there being about 120,000 regular physicians in this country. It had seemed to the committee on reorganization that it was logical to begin with the county, making that the unit, the next step being the state organization, and the third the National organization. The committee decided to start with a unit of ten, that being the basis of representation in the national body, THE AMERICAN MEDICAL ASSOCIATION. The controlling idea was "home rule," and the necessity for preventing any clique from getting control. The details of the plan were then explained, and the advantages pointed out. The members were urged to join the National organization, not only for the ordinary advantages of such membership, but because in this way one receives one of the best medical journals in the country—THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Continuing, the speaker said that there existed a very general misunderstanding regarding the position of the regular profession toward homeopathy. He would not, he said, personally belong to any association that would endeavor to hamper him in his treatment of disease. A man may hold as many dogmas and peculiar views as he chooses to believe in, and still be a member of the regular profession, provided he is willing to be called simply a "physician" and not desire to be looked on as a disciple of a certain sect, thus placing himself in antagonism with the great mass of educated physicians. There is nothing in the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION which prevents consultation with homeopaths under certain reasonable restrictions—certainly nothing which would operate to the disadvantage of the patient or the interests of humanity.

At the close of this address, the following resolution was unanimously adopted:

Resolved, That the First District Branch Association does express its approval of the proposed plan of reorganization of the New York State Medical Association.

International Congress of Hygiene and Demography.

Held at Paris, August 10 and 15.

Three-fourth of the 1500 members of this congress were official delegates from boards of health and hygienic associations. Physicians were numerous and prominent, but legislators, architects, etc., were well represented. Brouardel stated in his opening address that mothers could now be comforted with the assurance that the danger of contracting "croup" is only one-half what it was five years ago, while the chances of a fatal termination have been reduced by four-fifths. He added that one of the diphtheria wards in the Paris hospitals is about to be closed on account of disuse. He referred with especial approbation to the charts exhibited at the Exposition by the United States state boards of health, which portray with remarkable clearness the progress accomplished in the last ten years in the reduction of the general mortality and of that from diseases of known origin.

Roux discussed the means of measuring the activity of serums, and Riche called attention to the constant danger of insidious lead-poisoning from the lead used in the manufacture of the tin and enamel dishes for cooking and holding foods and drinks. In the discussion of proposed health-restrictions to marriage, certain members protested against the policy of frightening of prospective bridegrooms, as marriages are already far too infrequent, especially in France.

The resolutions adopted by the congress recommend, among other measures, that professional diplomas be awarded to plumbers, that streets and back-yards be widened, that tin cans be imprinted with the date of sealing, that water-pipes be placed where least liable to freeze, that cremation be more generally adopted, that employees in industrial establishments be protected from dust, etc., as much as possible and wear masks or spectacles. Warning circulars should be conspicuously posted pointing out the dangers of disregarding these measures. Ships trading with plague-infected ports should be supplied with antiplague serum. International prophylaxis of contagious diseases is best promoted by the presence of a physician as a sanitary official on ships. A person with a contagious disease should not be carried in an ordinary railroad car. One resolution was to the effect that as conductors of public vehicles have not the power to prevent expectoration on the floor, some other means should be devised to put an end to this promiscuous habit. The section for Industrial Hygiene adopted a set of resolutions so revolutionary in tone, that they were not even presented to the general congress, but were left as seed to germinate for the next congress, which will be held in Brussels in 1903, where the first international congress of hygiene convened fifty years before. One of these revolutionary resolutions mentioned was proposed by Pinard, and urged that salaried women should be entitled to rest during the last three months of pregnancy. He affirmed that prematurely born infants are handicapped all their life by the deficient development of their organs and tissues.

One of the most important measures adopted by the congress was that advocating a uniform international classification of the causes of deaths, to facilitate ready comparison of statistics. The classification used in the Paris municipal reports was accepted as the standard, and the *Semaine Méd.* of August 12 brings us word that all the delegates, except one, agreed to urge its adoption in their respective countries, to commence officially with the new century, January 1, 1901.

The Paris classification is as follows: Typhoid fever, M. 11, F. 15, T. 26; typhus; smallpox; measles; scarlet fever; whooping cough; diphtheria, croup; grippe; phthisis pulm.; tub. meningitis; other tuberculoses; cancerous tumors; other tumors; simple meningitis; cerebral congestion and hemorrhage; paralysis; softening of the brain; organic heart disease; acute bronchitis; chronic bronchitis; bronchopneumonia; pneumonia; other affections of respiratory apparatus; gastroenteritis, bottle fed; gastroenteritis, breast; diarrhea from 1 to 4; diarrhea over 5; puerperal fever and peritonitis; other puerperal affections; congenital debility; senility; suicides; deaths from other violence; other causes of death; unknown; still-births.

Paris was able to show the delegates over a model hygienic, altruistic, factory village, a great chocolate plant with 2000 employes. It also invited the members to sample the limpid water flowing off from the sewage farms, while decorating them with roses—the tangible expression of the solids of the sewage.

Rocky Mountain Interstate Medical Association.

Third Annual Convention, Butte, Mont., August 29-30.

President Dr. Charles K. Cole, of Helena, Mont., called the association to order at the Court House. The committee on necrology reported on the deaths of Drs. E. R. Axtel, of Denver, and Henry Chappell, of Livingston, Mont.

TUBERCULOSIS PROBLEMS.

DR. A. MANSFIELD HOLMES, of Denver, considered some problems pertaining to tuberculosis. One-seventh of the deaths are due to this disease, and, therefore, one-seventh of the population is tuberculous. He then spoke of the effect of the mountain region on the disease, exposure and remedies, and then took up the difficulties which the tuberculous patient encounters, who is unwelcome at health-resorts, hotels and boarding houses, and who finds it difficult to obtain employment on account of the nature of the disease. He urged the establishment of sanatoria.

DR. EDGAR P. HERSHEY, of Denver, recommended segregation by aggregation.

DR. ROBERT LEVY, of Denver, commended the accommodations offered by his city for consumptives, but agreed that the comforts of home were not to be ignored in these cases.

DR. LOUIS BERNHEIM, of Butte, spoke of the scarcity of tuberculosis in Montana. The smoky season in Butte should be avoided, but he considered the Montana climate as conducive to the cure of the disease as that of any other state in the union.

RENAL CALCULUS.

DR. HARRY D. NILES, of Salt Lake City, took up the diagnosis of renal calculus. The symptoms of this condition are often so masked and so similar to those of other diseases, such as vesical calculus, appendicitis, enterolithiasis, that the differentiation requires the greatest care and alertness. Stone in the kidney he considered as of relatively frequent occurrence. Early diagnosis is of more value than improved methods of operative technique.

DR. CHARLES M. CHAMBLISS, of Bozeman, Mont., endorsed the views of the essayist, had met with cases wrongly diagnosed, but stated that cases of renal calculus are infrequently met with in Bozeman.

DR. JAMES F. SPELMAN, of Anaconda, Mont., suggested that lumbago, sciatica and neuritis be added to the list of disease conditions which may make the diagnosis of renal lithiasis difficult.

DR. J. R. E. SIEVERS, of Butte, had noticed that occasional uranalyses often disclosed diseased conditions in patients who were apparently in sound health.

GASTRIC FEVER IN CHILDREN.

DR. G. T. MCCULLOUGH, of Missoula, Mont., discussed bilious fever as a disease of children. It was more prevalent, he said, in the Rocky Mountain district than in lower altitudes. He enlarged upon the etiology and symptomatology of the disease. The thermometer furnished the best means of differential diagnosis from typhoid, and the rash from scarlet fever. He then took up the treatment and urged that the patient be given plenty of water on the theory that the system craves and demands what the inflammation consumes.

DR. JOHN W. GUNN, of Butte, said that calomel was his favorite remedy in this disease. He did not approve of the use of aconite.

DR. W. FREDERICK MCCRIMMON, of Butte, suggested mild remedies for children suffering from biliousness and laid especial stress on the use of ice instead of water.

DR. LOUIS BERNHEIM, of Butte, did not think that a cold would bring on biliousness. He considered it due to a retardation of digestion, the result of ingestion of unsuitable or improperly prepared food. He favored mild remedies and mustard plasters, and did not approve of the employment of too much medicine, chloroform, morphin, etc.

DR. JAMES F. SPELMAN, of Anaconda, Mont., also considered that the essayist gave too much medicine. He favored rest of the stomach by abstinence from irritating foods and medicine.

DR. WALTER R. PIKE, of Provo City, Utah, took up the questions of temperance and perspiration and their action on the child suffering from gastric trouble. He also spoke for little medicine.

FRACTURES OF THE LOWER JAW.

DR. JAMES F. SPELMAN, of Anaconda, Mont., reported three interesting cases of compound fracture of the lower jaw in which the treatment was attended by excellent results. Other members of the association congratulated the operator on his results but criticised or discussed points in the technique of his procedures.

Papers were read also by Dr. Edgar P. Hershey, of Denver, on "Pilocarpin in the Treatment of Inebriety;" Dr. Samuel D. Hopkins, of Denver, on "Clinical Significance of Tremor," and Dr. Thomas A. Grigg, of Butte, on "The Use and Abuse of Glasses."

The following officers were then elected for the ensuing year: Dr. Carey K. Fleming, of Denver, president; Dr. Harry D. Niles, of Salt Lake City, Utah, first vice-president; Dr. Frederick F. W. McCrimmon, of Butte, Mont., second vice-president; Dr. Charles G. Plummer, of Salt Lake City, Utah, treasurer; Dr. Edgar P. Hershey, of Denver, recording secretary; Dr. Samuel D. Hopkins, corresponding secretary; board of trustees: Montana, Dr. T. J. Murray, of Butte; Colorado, Dr. A. Mansfield Holmes, of Denver; Wyoming, Dr. James Carter, of Carbon; Arizona, Dr. Charles H. Jones, of Tempe; Utah, Dr. Walter R. Pike, of Provo City; Idaho, Dr. James H. Bean, of Pocatello.

The 1901 meeting will be held in Denver the first Tuesday in September.

Therapeutics.

Insomnia.

Dr. Bradbury states that in the treatment of insomnia the great principle of therapeutics—the removal of the cause—should ever be kept in mind. The following is his classification of the causes of insomnia:

1. *Irritative Causes.*—This class includes the insomnia caused by pain and milder irritations, such as teething, indigestion, worms, eye-strain, facial adenoids, cold feet, asthma, vesical irritation.

2. *Toxic Causes.*—Alcoholism, gout, nicotism, gastric and intestinal disorders, Bright's disease, tea, coffee, drug habits, etc.

3. *Psychical Causes.*—Grief, shock, worry, mental anxiety.

4. *Causes Arising from Changes in Mode of Living.*—Late dinners, change of climate, women at the menopause, the various forms of insanity, etc.

It may be stated in this connection, as mentioned in an article in the *Therapeutic Gazette*, that the abuse of hypnotics in the treatment of insomnia is due: 1, to the carelessness of the physician in prescribing for the symptom insomnia and not seeking the cause; 2, to the reckless prescribing by druggists. It is unnecessary to state that simpler methods should be resorted to before medicinal treatment. The condition of the patient and the heart and arterial system should be ascertained before treatment is begun.

The following prescriptions represent good combinations which may be given in the different forms of insomnia, as the severity of the case may require:

℞.	Hypnal	ʒiii	12
	Syrupi simplicis, q. s. ad.	℥ii	64

M. Sig. One teaspoonful at bedtime, and repeat in two or three hours if sleep is not sooner produced.

Hypnal is a combination of chloral hydrate, 165.5 parts, and antipyrin, 188 parts. It is colorless, crystalline and soluble in six parts of water. The heart should be examined before its administration.

℞.	Chloralamid	ʒiss	6
	Liquoris ammonii acetatis	ʒiv	16
	Aquæ destil., q. s. ad.	℥iii	96

M. Sig. One tablespoonful at bedtime in water.

Chloralamid is a product of interaction between chloral hydrate and formamid. It is colorless, crystalline, soluble in twenty parts of cold water, and is a good substitute for chloral. It is not so powerful, so depressant nor so rapid in its action. It may be prescribed in powder form, to be dissolved in cold water, as hot water decomposes it.

℞.	Trionalis	ʒiss	6

Ft. pulveres No. vi. Sig. One powder in hot water at bedtime.

Trional differs from sulphonal in the replacing of a methyl by an ethyl group. It is colorless, crystalline, soluble in 320 parts of cold water, and freely soluble in hot water. It is more powerful than sulphonal as a hypnotic, but fully as safe. Habermann recommends that it be given in carbonated water.

Trional is of advantage over sulphonal in that it can be administered for a prolonged length of time, and does not cause the circulatory, digestive nor renal disturbances. In chronic psychic disorders it is said to act more promptly, as in insomnia from maniacal excitement or alcoholic delirium, but is not indicated in melancholia or hypochondriasis, as it increases the nervous depression.

—*Amer. Year-Book of Med.*, 1896.

℞.	Sulphonal	ʒiss	6

Ft. pulveres No. vi. Sig. One powder in hot water three or four hours before bedtime.

Sulphonal is colorless, crystalline, tasteless, soluble in 500 parts of cold water and 15 parts of boiling water. In cases of insanity, where it is difficult to administer medicine to the patient the powder may be placed in his soup. It seems from the literature that more harm may come from sulphonal than is ordinarily supposed. It is advised not to prescribe sulphonal continuously, and to carefully examine the urine from time to time during its administration. Another objection to sulphonal is that its action may be delayed until the following day, and then produce symptoms of drowsiness lasting for several hours. Priestly's advice is that after a week's administration it should be dropped for three or four days, and by keeping this point in view it is unattended by danger, except when the kidneys are diseased. The maximum dose for men is 30 grains and for women 15 grains.

℞.	Potassii bromidi	ʒii	8
	Liquoris potassii arsenitis	ʒss	2
	Aquæ cinnamomi, q. s. ad	℥vi	192

M. Sig. One to two dessertspoonfuls at night in water.

Hare recommends the above combination of bromids and arsenic in females with a weak heart where chloral is contraindicated. The arsenic prevents the production of acne.

R. W. Wilcox, in the *Med. News*, April, 1900, states the following concerning the requirements of a hypnotic which approximates as closely as possible the theoretical agent: 1, it must combine one of the alcohol radicals; 2, it must be free from depressant action on the heart and vessels; 3, it must not derange assimilation; 4, it must be safe, reliable and palatable, and he regards chloretone as nearest approaching these requirements.

℞.	Tablets chloretoni, āā	gr. iii-vi	18-36

No. xv. Sig. One every two or three hours until sleep is produced.

This preparation is a white, crystalline substance, having a camphoraceous odor. It is formed through the interaction of chloroform, acetone and alkali. It is fully soluble in water. It is a local anesthetic as well as hypnotic. Its principal action is said to be on the cortical cells of the brain and it has practically no effect on the centers in the medulla, and from the statements concerning this preparation it can be given in very large doses with no ill effects.

Dr. C. J. Douglas, of Boston, has obtained good hypnotic results from the following:

℞.	Tablets apomorphiæ hydrochloratis, āā	gr. 1/30	002

Sig. To be given hypodermically at bedtime.

INSOMNIA FROM FUNCTIONAL NERVOUS DISTURBANCES.

℞.	Tinct. lupuli	ʒi	4
	Sodii bromidi	gr. xv	1
	Aquæ chloroformi, q. s. ad	℥iss	48

M. Ft. haustus. Sig. At one dose, to be taken at bedtime.

℞.	Paraldehydi	ʒiiss	10
	Syrupi aurantii	ʒiv	16
	Spiritus vini rect.	℥iss	48
	Aquæ destil.	℥ii	64
	Syrupi simplicis, q. s. ad	℥v	160

M. Sig. One tablespoonful at bedtime.

Paraldehyde is obtained by the action of sulphuric acid on aldehyde. It is a clear fluid, with a disagreeable taste. It is said that it will not depress the heart, but is apt to disturb the stomach. It should be administered as above, or with equal parts of oil of sweet almonds.

NIGHT TERRORS.

R.	Potassii bromidi	ʒii	8
	Tinct. hyoscyami	ʒi	4
	Syrupi simplicis, q. s. ad	℥iii	96

M. Sig. One teaspoonful at night in water to a child of 4 to 6 years of age. —*Dominion Med. Monthly.*

The bromids increase the hypnotic effect of the hyoscyamus.

℞.	Ammonii bromidi		
	Sodii bromidi		
	Vini antimonii, āā	ʒss	2
	Syrupi simplicis	℥i	32
	Aquæ menthæ pip., q. s. ad	℥vi	192

M. Sig. One teaspoonful at bedtime. —Gould and Pyle.

IN MILD FORM OF INSOMNIA.

℞.	Tinct. sumbul (B. P.)	℥i	32

Sig. Twenty or thirty drops in water at bedtime.

℞.	Ext. hyoscyami	gr. viii	5
	Ext. conii	gr. xv	1

M. Ft. capsulæ No. viii. Sig. [illegible] two or three hours.

INSOMNIA DURING DENTITION.

℞. Chloralis hydratis ....gr. viii | 5
Sodii bromidi ....gr. xv | 1
Syrupi lactucarii
Aquæ destil., āā ....℥ss | 16

M. Sig. One teaspoonful every hour until quiet, for a child of 6 months or older. —Gould and Pyle.

INSOMNIA IN FIRST STAGE OF PLEURISY.

℞. Codeinæ
Pulv. ipecacuanhæ, āā ....gr. iii | 18
Pulv. camphoræ ....gr. xv | 1
Quininæ sulphatis ....gr. xii | 72

M. Ft. capsulæ No. xii. Sig. One capsule every three or four hours.

INSOMNIA OF ASTHMA.

℞. Tinct. lobeliæ ....ʒiv 16
Morphinæ sulphatis ....gr. 1/3 | 02
Elixiris simplicis, q. s. ad...........℥ii 64

M. Sig. One teaspoonful at night or during the attack, and repeat in two hours if necessary.

℞. Ammonii bromidi ....ʒii 8
Aquæ camphoræ ....℥i 32
Elixiris simplicis, q. s. ad.............℥ii 64

M. Sig. One dessertspoonful at night in water. To be repeated in two hours if required.

INSOMNIA DUE TO INCOMPETENT HEART.

℞. Tinct. digitalis ....℥ii 64

Sig. Five to ten drops in water every four or five hours.

IN CHRONIC BRIGHT'S DISEASE.

℞. Chloralis hydratis ....ʒi 4
Syrupi aurantii ....℥i 32
Syrupi simplicis, q. s. ad.............℥ii 64

M. Sig. Two teaspoonfuls at bedtime in water.

INSOMNIA DUE TO GASTROINTESTINAL DISTURBANCE.

℞. Sodii carbonatis ....ʒiss 6
Spiritus ammoniæ arom...............ʒv 20
Ammonii bromidi ....ʒiss 6
Tinct. cardamomi comp..............℥i 32
Aquæ menthæ pip., q. s. ad..........℥iv 128

M. Sig. One dessertspoonful at bedtime, and repeat in one hour if necessary.

INSOMNIA DUE TO OVERWORK OR WORRY.

℞. Olei terebinthinæ ....gtt. xxx 2

Sig. In capsule at one dose as a stimulant. —Bradbury.

INSOMNIA OF ALCOHOLISM.

℞. Tablets strychninæ sulphatis, āā...gr. 1/30 | 002

Sig. One tablet hypodermically, and repeat in four hours if necessary.

℞. Tablets strychninæ sulphatis, āā...gr. 1/30 | 002
Potassii bromidi ....ʒiv 16
Elixiris simplicis, q. s. ad...........℥iii 128

M. Sig. One dessertspoonful at bedtime in water.
—Clouston: *N. Y. Med. Journal.*

℞. Syrupi zingiberis
Spiritus ammoniæ arom.
Tinct. valerianæ, āā ....℥ii 64
Sat. sol. potassii bromidi, q. s. ad....℥viii 256

M. Sig. One tablespoonful in water every three or four hours.

INSOMNIA OF ACUTE ALCOHOLISM.

℞. Sodii bromidi
Chloralis hydratis, āā.............gr. xv 1
Tinct. hyoscyami ....m. xv 1

M. Sig. At one dose. Repeat in one hour if necessary.
—D. R. Brower.

℞. Chloralamid ....gr. xv 1
Hyoscinæ hydrobromatis........gr. 1/100 | 0006

M. Sig. At one dose. —D. R. Brower.

INSOMNIA OF ACUTE ALCOHOLIC PNEUMONIA.

R. Codeinæ ....gr. ii | 12
Elixiris chloralamid (gr. xx to ℥i).....℥ii 64

M. Sig. One tablespoonful, to be repeated in two hours if necessary. —A. A. Smith: *N. Y. Polyclinic.*

INSOMNIA OF DELIRIUM TREMENS.

℞. Chloralis hydratis ....ʒiv 16
Tinct. capsici ....℥i 32
Aquæ menthæ pip....................℥v 160

M. Sig. One tablespoonful every two or three hours until sleep is produced. —Gould.

INSOMNIA OF CONVALESCENCE FROM ACUTE DISEASE.

℞. Somnal ....ʒiv 16
Elixiris simplicis, q. s. ad.............℥ii 64

M. Sig. One teaspoonful in water at bedtime; repeated in three hours if necessary to produce sleep.

Somnal is a compound of chloral, alcohol and urethane.

Khmelewsky, in the "Year-Book of Medicine," states that in melancholia and simple insomnia, somnal acts better than any other hypnotic; that it is not accompanied by any disagreeable subjective symptoms on awakening; that it does not seem to affect the heart. The principal non-indication is in producing gastrointestinal disorders.

INSOMNIA OF MELANCHOLIA.

Dr. Weatherly, in the *Bristol Med.-Chir. Jour.*, advises the following prescription:

℞. Phenacetini ....gr. x | 66

Sig. At one dose and repeat in an hour if necessary.

℞. Morphinæ sulphatis ....gr. 1/12 | 005

Sig. At one dose and repeat once or twice during the day if necessary.

℞. Tablets hyoscinæ hydrobromatis,
āā ....gr. 1/150 | 0004

Sig. At one dose hypodermically.

Hyoscine is indicated especially in agitative form of melancholia. The presence of heart lesions would contraindicate its use.

INSOMNIA OF HYPOCHONDRIA.

℞. Urethane ....ʒiv 16
Elixiris simplicis, q. s. ad............℥iv 128

M. Sig. One dessertspoonful in water at bedtime.

Urethane is obtained by heating a salt of urea with ethyl alcohol. It is soluble in water or alcohol; is colorless; has a saltpetre taste, and is crystalline. It is said to have no unpleasant after-effects, and can be given in insomnia due to mitral insufficiency.

INSOMNIA OF HYSTERIA.

℞. Potassii bromidi ....ʒiv 16
Chloralis hydratis ....ʒiii 12
Tinct. asafœtidæ ....ʒiv 16
Syrupi simplicis ....ʒvi 24
Aquæ destil., q. s. ad.................℥vi 192

M. Sig. One tablespoonful every three hours until sleep is produced. —Potter.

INSOMNIA DURING CLIMACTERIC.

℞. Ammonii bromidi ....ʒiii 12
Tinct. humuli ....ʒvi 24
Aquæ camphoræ q. s. ad.............℥iii 96

M. Sig. One dessertspoonful in water at bedtime.

Bradbury recommends the above combination. He states that it is of use in relieving the insomnia as well as the mental depression and flushing heats so common at this period.

INSOMNIA OF NEURASTHENIA.

℞. Chloralamid
Tinct. zingiberis, āā.................ʒiv 16
Aquæ menthæ pip., q. s. ad ....℥iv 128

M. Sig. One tablespoonful at bedtime in water.
—*Presse Médicale.*

Dr. Arthur Schüller (*N. Y. Med. Journal*, June 30, 1900) recommends the following for the insomnia in neurasthenia, hysteria and alcoholism:

℞. Hedonal ....ʒv 20
Tinct. cinnamomi ....ʒi 4
Elixiris aromatici, q. s. ad...........℥iii 96

M. Sig. One dessertspoonful at bedtime.

He states that the dose ranges from 18 to 22 grains, and advises it given in the above form on account of the disagreeable taste.

℞. Lupulini
Pulv. camphoræ
Ext. hyoscyami, āā..........................gr. iii 18

M. Ft. capsulæ No. ii. Sig. One at bedtime, and repeat in an hour or two if necessary. —Steward.

NERVOUS INSOMNIA.

Render a tumblerful of sour curds and whey alkaline with sodium bicarbonate; *sweeten and grate nutmeg on top;* serve hot. —*Med. Record.*

INSOMNIA DUE TO FUNCTIONAL DISORDERS.

Dr. J. W. Courtney's article on the treatment of insomnia due to functional disorders, in *Personal Hygiene*, contains the following suggestions:

1. Mental work should be performed during the first part of the day and be limited to four or six hours.
2. The bed-chamber should be cool, the bed hard and the covers light.
3. Care should be taken that the feet do not get cold, since the sensory stimuli prevent sleep.
4. A glass of warm milk or a cup of bouillon or even a glass of beer or a small quantity of food. (Avoid any large amount of alcohol.)
5. Counterirritation by application of bottles of warm water to the feet and back, and warm compresses over abdomen.
6. Very gentle massage to the back of the head and neck or gentle rubbing to the whole body, beginning with the lower extremities and working up; but this should not be done after 6 p. m., and never longer than five or six minutes at a time.

Medicolegal.

Constitutionality of Licensing Lying-in Asylums.—Section 288 of the New York penal code provides that a person who, "not being a superintendent of the poor or a superintendent of alms-houses, or an institution duly incorporated for the purpose, without having first obtained the license in writing so to do from the board of health of the city or town wherein such females or children are received, boarded or kept, erects, conducts, establishes or maintains any maternity hospital, lying-in asylum, where females may be received, cared for or treated during pregnancy, or during or after delivery," is guilty of a misdemeanor. This was averred to be unconstitutional, in the case of People vs. Hagan. But it is upheld by the first appellate division of the Supreme Court of New York. The latter says nothing in this section would prevent a person from properly caring for another boarding or living with her during pregnancy. It is the maintenance of an institution or lying-in asylum which is conducted or maintained for that purpose that is prohibited. Undoubtedly, to justify a conviction under this section, the court continues, it would be necessary to prove that the person charged had either erected, conducted, or maintained such an institution—an institution which has for its object the care of persons who are pregnant, or during or after their delivery. The requirement of a license for such an institution is to enable the public authorities to make proper sanitary regulations as to such institutions, so that inmates should not be exposed to infection, or the dangers that arise from improper uses. So, while no attempt is made to regulate the confinement of persons wherever they happen to be living, but the legislature has deemed it proper to regulate institutions or hospitals established or maintained for the treatment of such persons, the court thinks that such a regulation comes clearly within the power of the legislature. There can be no doubt, it says, that an institution in an unsanitary condition, receiving persons to be cared for during or after delivery, and in charge of incompetent persons, might cause great injury to those who become inmates thereof; and, therefore, a provision that, before a person can maintain such an institution, he must, by procuring a license from the health authorities, satisfy them that the arrangements are such that inmates will receive proper care and attention, the court holds, is within the power of the legislature.

Contract Not to Practice in Place for Ten Years.—A practicing physician, located in a town in Texas, sold to another his homestead. His wife joined in the deed in the usual manner. But, besides the usual provisions, the deed contained one stating that he, the selling physician, agreed not to locate in that town, or within a radius of ten miles of the town, to practice medicine, for the space of ten years from the date of the deed, his intention being thereby to convey his good will as well as his property. Thereafter, the purchaser brought suit on this contract, and recovered a judgment of $10 damages, and obtained an injunction restraining the seller from locating or establishing an office in the town referred to, or within a radius of 10 miles thereof, to practice medicine and surgery within such town or a radius of 10 miles thereof, unless he should be sent for outside of such radius, or from a point outside of such radius, and from interfering with the complainant's practice of medicine by establishing or locating an office for the purpose of practicing medicine and receiving calls from patients within a radius of 10 miles from said town, until the expiration of said 10 years. And the Court of Civil Appeals of Texas affirms the judgment of the court below. It points out that the restriction was limited as to area and as to time, and that it did not, as to such area, totally exclude the defendant from practice, the effect of the contract being to restrain, or within 10 miles therefrom, for 10 years. It is clear, from the authorities, the court thinks, that the agreement was not void at common law. Nor does it consider it invalid under the Texas statute against combinations in restraint or trade or preventing competition. It explains, case of Wolff vs. Hirschfield, that a transaction of this character is not rendered invalid, by the statute, for the reason that it is not a combination of persons, and because it is a sale of "good will," which is a subject of purchase and sale; that is to say, property. That the home sold did not necessarily have any connection with the practice sold the court does not think made any material difference. It says that if, as the authorities hold, the practice of a physician is a thing of value, and as such is a proper subject for a contract of sale, a sale thereof, with such contract restrictions as are reasonably necessary to make the sale effectual, will not fall within the prohibition of the statute mentioned.

Removal of Smallpox Patients to Pest-House.—Hengehold vs. City of Covington, the Court of Appeals of Kentucky says, was an agreed case wherein it was asked to decide these questions: 1. Has a city of the second class, in Kentucky, power to pass an ordinance providing for the removal of smallpox patients to a pest-house? 2. Can such city by ordinance vest such power, to remove such persons so afflicted to a pest-house, in its health board, or in any three members thereof, or in the health officer. 3. Can such removal of persons so afflicted be made by the board of health or by the city health officer, notwithstanding the physician attending the patient shall certify in writing that the patient's life would be endangered by such removal, or that he has good and careful attention, and his removal would not be advisable as a sanitary measure? In answering these question, the court says that the preservation of the public health has always been held a proper exercise of police power. There can be no doubt that in order to prevent the spread of disease, and to provide healthful conditions for the public, boards of health and like commissions may be created, and invested with power necessary and proper for such purposes; and, in determining the validity of the acts of such boards and their officers, a liberal construction is justified, in view of the public good to be accomplished. There can be no doubt of the power of the state legislature to create state boards of health for the preservation of the general health of the state, to confer upon cities and counties authority to make regulations for the health of their communities, and even to create separate corporations, differing from the political subdivisions, with like powers within their limits. Both in England and the United States such powers have been almost uniformly delegated to boards of health of municipal corporations to enact rules for the preservation of the public health, having the force of law within the respective communities; and it would seem that, in the absence of express authority, municipalities have an implied power to enact reasonable ordinances to preserve the public health and to prevent and remove nuisances. Under its general powers to guard against epidemic diseases, a board of health may control and isolate persons affected with the disease. And this power, the court goes on to say, seems to be expressly delegated to the local boards by the provision of the Kentucky statutes which empowers them to inaugurate and execute such sanitary regulations as the local board may consider expedient to prevent the outbreak and spread of epidemic diseases, and to this end may bring the infected population under prompt and proper treatment during premonitory and other stages of disease. It is certainly a reasonable regulation, the court thinks, which provides for the removal of such cases to a pest-house in good sanitary condition, provided with nurses and physicians for the treatment of patients suffering with the disease. Therefore the court is of the opinion that the local board, or a quorum thereof, has undoubtedly power to order the removal of an infected patient to the pest-house. Taking up what it denominates a narrower question, the court calls attention to its being a general rule upon this subject that laws establishing state boards, and laws establishing local boards, shall be construed together, so as to give effect to both. Applying this rule, in this case, to the general law as to the powers of local boards and the charter of cities of the second class, in Kentucky, which expressly authorizes them to establish and enforce quarantine laws and regulations to prevent the introduction and spread of contagious diseases, and to secure the general health of the inhabitants by any necessary measure, the court says that it follows that the city is authorized to make additional reasonable regulations to prevent the spread of epidemic diseases. And a regulation empowering three members of the board, or the health officer elected by the board, to order the removal of a smallpox patient, it holds, is a reasonable regulation, especially where there is provided an appeal to the board, and a requirement of action by the board itself upon a certificate by the attending physician that the removal would endanger the patient's life. In such cases, it adds, the necessity for immediate action is imperative, and it is not unreasonable to permit the health officer, or less than a quorum of the board, to order such removal, in a case where it does not appear that the removal would endanger the patient's life.

1.—See abstract in THE JOURNAL, xxxiv, p. 1133.

2. **Bacillus Coli Communis.**—After a consideration of all the facts available, Linsley and Stone conclude that waters in which the bacilli coli communes are found to exist for any length of time are dangerous to the public health and should be condemned.

3. **Pathologic Physiology.**—In this lengthy article Levin discusses the various physiologic pathologies of the organs and functions, showing the position of pathologic physiology or experimental pathology in medicine and its importance to students and physicians.

4. **Ureine.**—Moor has found in the urine a new organic liquid, which he considers its most characteristic component, and describes the method of its isolation by treating with nitrate of silver and then with oxalic acid. The two principal rules to be kept in view are: 1, avoid high temperature; 2, use chemicals as little as possible. The substance resembles in aspect olive-oil, is of a pale yellowish color, slightly bitter to the taste, greasy to the touch, produces spots on paper, is about as heavy as glycerin, freely miscible in all proportions of water and alcohol, barely soluble in ether, and slightly alkaline in reaction. He thinks that it belongs to the group of alcohols of the aromatic series. It begins to split into different bodies at 80 C. belonging to the class of aromatic oxi-acids, and if heated to 150 C. leaves behind it pure carbon. It has a characteristic odor, that of urine; when rubbed on the skin it produces a slight burning sensation and is probably the principal cause of the irritative effects of urine. One of its most remarkable characteristics is its ability to take up large quantities of oxygen. He finds it surpasses urea as regards quantity, the greatest amount being contained in the urine voided between 5 and 7 p.m. He gives the results of experiments on animals, showing its toxicity and claims that it is the probable cause of the ammoniacal fermentation of urine, as without its presence urea can not be decomposed into ammonia and carbon dioxid. Without it he thinks all organic matter would be converted into urea which would remain in nature without any use.

5. **Tumors and Pregnancy.**—After first noticing the dangers of these growths in case of pregnancy, the author gives the statistics of Gusserow as illustrating the fact, and mentions the diagnosis, which is generally easily made when the tumor is on the anterior surface of the uterus, but may be difficult under other conditions. He advises that the patient be allowed to go nearly to term, when possible, and a Porro-Cesarean operation then be performed. When, however, the tumor grows from the lower posterior portion and fills the lower pelvic cavity, immediate hysteromyomectomy is advisable, and he reports a case illustrating its necessity.

6. **Atrophic Rhinitis.**—The causes of atrophic rhinitis are discussed by Logan, who finds none of the theories satisfactory. The hypertrophic origin may be dismissed, the theory of suppurative rhinitis in childhood, as suggested by Bosworth, might explain atrophic changes, but there is difficulty in understanding how the excessive secretion can be kept up by the atrophic tissue. The failure of inoculation experiments

is against Lowenberg's germ theory and the vital objection to all is the failure of explanation of the immense secretion. Logan thinks the middle turbinate is more liable to atrophy than the others, since its blood-supply is more limited and its tissue less resistant. He reports three cases.

22. **Tropical Dysentery.**—Flexner first reviews the history of the studies on the bacteriology of dysentery and concludes: 1, that no bacillus species yet described as a cause has any special claim to be the chief micro-organism in the etiology; 2, it is unlikely that any bacterial species that is constantly in the intestines or environments of man, except where the disease is endemic, can be considered as a probable cause of epidemic dysentery; 3, the relation of sporadic to epidemic dysentery is so remote that it is improbable that the two diseases are produced by the same organic cause; 4, the pathogenic action of the ameba coli in many cases of tropical and some of sporadic dysentery has not been disproved by the discovery of the ameba in the normal intestines and in other diseases than dysentery. While they are commonly present and concerned in the production of lesions in subacute and chronic dysentery, they have not thus far been shown to be equally connected with the acute dysentery even in the tropics. In the former varieties, bacterial association probably has much influence upon the pathogenic powers of the ameba. He next takes up the subject of dysentery in Japan and the Philippine Islands, noticing especially the statistics of Ogata and Eldridge and the bacterial studies and findings of Shiga; the organism found by the latter investigator seems to agree with the one found by Flexner and his associates in the dysentery of the Philippine Islands. The first type is a bacillus of the average size of B. coli communis, varying somewhat in the length, but almost none in the thickness, the ends slightly rounded, easily separated, markedly motile, and Gram's stain negative. It grows on all culture-media and is pathogenic to the ordinary laboratory animals. It is abundant in the acute cases, but is hard to find as they become chronic and was not found in the ordinary amebic dysentery of Manila. The second type is less numerous in acute cases and in its properties agrees well with those of the group of the colon bacillus. Tests were made as to the agglutinating power, pathogenic action and all peculiarities of Type I. He thinks that it is more closely allied to bacillus typhosus than to B. coli communis, but it differs from the former in being less markedly motile and losing its motility more rapidly; it is also more uniform in its generation of indol. After acid production in milk it gives rise to gradually-increasing alkalinity. It is inactive to blood-serum in typhoid cases, but reacts from serum in the dysenteric cases to which bacillus typhosus does not respond. He is inclined to think that acute dysentery is caused by this bacillus, while the most frequent type of chronic tropical dysentery is more likely to be due to the ameba. The serumtherapy has been experimented with by Shiga, who found in 65 cases decided reduction of the death-rate by this means. Flexner thinks that more benefit is likely to be derived from a sort of vaccination of those that are to be exposed to the endemic or endemo-epidemic dysentery of the tropics.

23. **Ventral Hernia.**—The improved technique of Johnson is described as follows: Ventral herniæ may be considered as median and extramedian: the former following median abdominal incisions; the latter resulting mostly from operations for appendicitis. An elliptical incision is made a little within the border of the opening in the abdominal wall. This must be done carefully, as there is frequently a loop of intestine adherent to the inner surface of the hernial sac. The skin and superficial fasciæ—if they can be distinguished—are then dissected back, exposing the sheath of the rectus muscle. On the outer side a similar dissection is made an inch or more over the external oblique. The edges of the opening are trimmed and a No. 25 silver-wire suture is inserted at the upper angle of the opening by lifting the abdominal wall and passing the needle through the peritoneum, rectus muscle and skin, about one inch from the free border of the opening. The needle on the other end of the wire is similarly passed through the abdominal wall on the opposite side. Silver-wire sutures are inserted at intervals of one inch throughout the entire length of the incision. All the subcutaneous tissues are then united by a continuous kangaroo-tendon suture, and the skin is closed by a continuous suture of the same material. The deep wire sutures are now taken up one by one, moving them back and forward, to make sure that a loop of gut is not included between the wire and the abdominal wall. The ends of the wire are wound around a piece of ivory on either side and drawn sufficiently tight to relieve the tension on the kangaroo-tendon stitches. This is the old and nearly obsolete "quill suture" used for a new purpose. Half the wires are removed in ten days and the remainder in fifteen days. When the hernia is in the median line the principle is the same. The object is to relieve the tension on the stitches which hold the muscular tissues together until firm union has taken place.

24. **Chronic Rheumatism.**—Walsh recognizes four types of conditions diagnosed as chronic rheumatism: 1. Recurring subacute rheumatism. 2. Symptoms of abarticular rheumatism, which occur over and over again during unsettled weather, especially in children. 3. This group is the one that really deserves the name. It contains the cases in which the joint-lesions that have occurred during an attack of rheumatism persist and even become worse by secondary degenerative processes continuing through years, sometimes leading to marked and lasting deformity. In this case the main point is to get the history of the original rheumatism. 4. This last class is not rheumatism in its proper sense, but includes various ailments characterized by pain, including forms of toothache, flat-foot, occupation neuroses, etc.

25. **Healthy Habitations.**—Engelmann's article is a plea for the reform of the lodgings of the poor, pointing out the defects that exist and suggesting their remedies.

26. **Gastroptosis.**—The treatment of gastroptosis described by Lincoln consists in removing pressure at the waist, good nourishment, relief from constipation, exercise, massage, electricity, bromids to relieve nervousness, tonics, etc. For mechanical treatment he has devised and describes a bandage, or rather a plaster application, in place of the binder, the results of which he thinks are more gratifying. Its action is to produce upward pressure on the lower abdomen.

29.—See abstract in The Journal of August 4, p. 293.

30. **Cancer of the Breast.**—The history of the treatment of cancer of the breast is noticed by Gage, who points out that two objects are to be aimed at: prevention of local recurrences and securing of longer immunity from disease. He analyzes some of the statistics that have been published, showing that with more thorough operation the local recurrences are less likely to happen and says also that there has been a steadily increasing percentage of cases that have passed the three-year limit without recurrence of the disorder. He believes that while the results are yet not what they ought to be, they are sufficient to convince him that in the thorough and complete removal of cancerous breasts we have a means of offering longer immunity from cancerous affections to a large proportion of these patients.

31. **School Chairs.**—The improper construction of school seats and their hurtful effects are noticed by Stone, who points out that lateral spinal curvature almost always originates during school life. The great defect has been in the failure to recognize that any attitude, no matter how good in itself, can be long maintained without causing fatigue, and he mentions especially the need of proper chair-backs. There are two essentials for consideration—under no circumstances should the shoulders be forced forward, that is to say, there should be a firm support for the sacrum and lumbar region, and at the same time there should be moderate support for the dorsal region up to the shoulder-blades. In this way the liability to round shoulders would be decreased and account is taken of the fact that full extension of the spine tends to prevent lateral curvature while flexion allows it. As an illustration he notices the typewriter chair-back, which has been found to be a financial success, as it meets the physical requirements.

36. **Antitoxic Globulins of the Blood-Serum in Diphtheria.**—Park has experimented with the use of the antitoxic globulins of the blood-serum instead of the whole serum, using

it diluted so that each cubic centimeter contains the same number of units as the original serum. He finds it rather more irritating, but otherwise equally efficient so far as the diphtheria is concerned, while the globulins retain their antitoxic properties for the greater part of two months. It is easily soluble and can be put up in tablets and thus readily transported. On the whole, however, his results are somewhat disappointing, as the globulins apparently contain a great number of the deleterious elements of the blood-serum and it does not appear that we can isolate these to any advantage in this way. The practical advantage appears to be that in this substance we have a soluble, permanent and compact dried antitoxin serum which will not quickly deteriorate.

41. **Railroad Injuries.**—Sinkler describes the condition of traumatic hysteria and neurasthenia, more especially in their medicolegal aspects. While he admits that absolute simulation is perhaps a rarity, he thinks exaggeration is extremely frequent, and mistakes are made sometimes greatly to the damage of the corporation sued. Usually, and probably in the majority of cases, the patient unconsciously exaggerates his condition. He reports the case of a would-be pensioner who was exposed by etherization. In making the examination of a patient who has been in an accident, the expert would best see him alone. He should be allowed to give a full account of the injury and its symptoms, carefully observing his manner and condition, and after the removal of the clothing, examine for scars, malformations, deviations of the spine and muscular rigidity, reflexes, sensibility in particular, etc. If the case is difficult to correctly diagnose, it is well to get the patient's consent to take ether on some pretext and this usually is infallible. The physician ought never to act as assistant and prompter to counsel and should try to be as impartial as possible. In conclusion he urges every one to discourage litigation on either side, as it has a bad effect, even when the injury has occurred, by keeping up suspense and expectation. We must always remember, too, that hysteria is not a fraud and does not exclude the existence of organic disease.

43.—See abstract in THE JOURNAL, xxxiv, p. 1130.

48.—See abstract in THE JOURNAL, xxxiv, p. 1338.

49. **Uterine Dislocations.**—First stating the normal relation of the uterus and the cause of its backward displacement, Hill holds that we must first remove the etiologic factors. When adhesions exist they must be thoroughly destroyed and the abdominal is better than the vaginal route for this purpose. When the cervix is drawn forward we should direct our efforts to overcoming this condition, which is usually done by repeatedly and forcibly carrying the cervix backward, though it may take time and trouble. The use of the pessary is described, and for operative procedure for shortening of the round ligaments he prefers the Alexander method. Vaginal fixation of the uterine body is condemned and ventrofixation he considers unscientific and illogical in principle, though he recommends it in old retroversions with adhesions, long uterosacral and small, round ligaments. He does not favor operating on the uterine tissue itself by removing a plug from the opposite wall.

50. **Conservative Operations on Ovaries and Tubes.**—From a review of 85 cases, Burrage deduces the following conclusions: 1. It is advisable to do conservative operations in all cases in which the ovaries and tubes are not hopelessly diseased in all parts of their structure, except in patients who are near the menopause, on patients who have pronounced gonorrhea of long standing, and on the rare cases of malignant disease. 2. When a patient is near the menopause—over 35 years of age—and has ovarian or tubal disease of any considerable degree of severity, it is generally wiser to perform complete removal, with or without hysterectomy, according as the uterus also is diseased or not. 3. In cases of well-marked gonorrhea of long-standing, especially if the patient is constantly exposed to reinfection, if both tubes are seriously diseased and closed, total removal with or without hysterectomy is the operation of choice. 4. In certain cases of this class where the patient thoroughly understands the likelihood that another operation may be necessary at some future time, and wishes to take the chances in the hope of preserving the function of menstruation, conservative operation is permissible. 5. If one tube is patent and healthy in appearance and there is enough healthy ovarian tissue to preserve, a conservative operation ought to be performed even in the presence of gonorrhea. 6. With present methods of performing resection of the tubes, if both tubes are found closed at the time of operation, subsequent pregnancy is not to be expected. 7. In severe grades of inflammation of the appendages, irrespective of causation, if the ostium abdominale of one tube is patent, the prospect of subsequent pregnancy after the preservation of a portion of ovary is about one in four and a quarter, or 23.5 per cent. 8. In the less severe grades of inflammation, under similar conditions of tube and ovary, the prospect of subsequent pregnancy is about one in two and a quarter, or 44 per cent. 9. In women who have borne children, in both classes, subsequent pregnancy may be expected in 35 per cent., whereas in the previously sterile it may be looked for in only 5 per cent. 10. If it is necessary to remove both ovaries, it is of no advantage to preserve any portion of tubal tissue, but, except under conditions just enumerated, some ovarian tissue should be preserved in every case.

52. **Hernia in Children.**—Balloch concludes from his study of the subject that hernia is not an infrequent condition in children and of the different types, the umbilical is generally cured without operation, the femoral never, and the inguinal in from 70 to 80 per cent. of the cases. In view of the serious handicap in the battle of life caused by hernia, it is justifiable and proper to recommend operation for the radical cure in children who have faithfully worn a truss for two years without benefit. The mortality is less than would result from accident if operation was neglected.

62.—See abstract in THE JOURNAL, xxxiv, p. 689.

66. **Venous Pulsation in the Fundus Oculi.**—After two years' study of his clinical observations, Weymann makes the following report, in substance: Venous pulsation on and about the disc is very common, perhaps more frequent under ordinary physiologic conditions. It is most easily seen in physiologic excavations, and where the veins twine around the arteries or make a loop as they emerge from the crater-like center of the disc. In such places the veins look darker, owing to the doubling of the blood-column due to superimposition. The venous pulsation differs from the arterial pulse seen in hypertension of the ball. The latter is a true pulse, quick and flash-like, synchronous with distended arteries, while the former, though equally frequent, is not thus synchronous. It appears later, is slow and heaving, and easily followed in its wave. It is most prominent where the veins are largest and is lost as the caliber diminishes, hence the condition is not a true wave caused by internal distension. It is not a true pulsation, but is without doubt produced by such. The pulse expansion compresses the lumen of its accompanying vein, which action, in damming up the venous flow, becomes more accentuated by the circumstance that it travels in the direction opposite to the venous current. Whenever the two vessels are sufficiently far apart, no such effect can be produced.

71. **Pterygia.**—Weymann advises the removal of all pterygia; though they may become sometimes non-progressive, undue procrastination may have serious consequences. The methods for destruction of the head may vary, but they should all produce a thorough and smooth removal, be entirely free from danger, and cause sufficient plastic reaction to result in a firm scar opposing conjunctival traction. The best means, in his opinion, is a very thin galvano-cautery knife, with the blade bent about 45 degrees to its insertion, and it should not be held any farther from the fingers than about two inches to do good work. A full-fledged pterygium excision is the only correct plan, and the following operation is described as the most radical one, in his opinion: After cocainizing and flooding the conjunctival sac, to remove the excess of alkaloid, the neck of the pterygium is grasped with an iris-forceps and gently pulled from the ball to avoid cutting healthy conjunctiva. A very narrow and sharp-pointed cataract knife is made to pierce the tissues in such a way that the neck is separated from the adjoining healthy lining without any loss of the latter. A pair of scissors is started at the incisions and caused to delimit the

growth, both below and above, nearly as far as the plica semilunaris. From this point both incisions are joined by two converging cuts meeting at, or near, the caruncle. Raising the inner end, the operator now separates the growth from the eyeball as far as the head, always tensing it as he clips adhesions, with the scissors against the pterygial body. The head is detached by a slow, see-saw motion of an ordinary cataract knife or lance and the roughness of adjacent parts worn down by the galvano-caustic spatula. After flooding the eye, inspection will show an amount of subconjunctival vascularization and it will be seen that, in bad cases, it reaches farther over the globe than did the body of the pterygium. This vascular matting should be pulled out and thoroughly excised. A tenotomy hook is now passed under the lining to be approximated in order to break up adhesions. Near the sclerocorneal junction smart traction is made to allow the unobstructed passage of the scissors for the "accommodative incisions." Four or five sutures are then passed—not thicker than No. 6—by a curved round needle, to avoid cutting and tearing the membrane. The first stitch should be as close to the corneal margin as the accommodative incisions will allow. A pair of very small curved scissors will now be made to detach the conjunctiva along the limbus corneæ, both above and below, for a distance of nearly one-fourth the total circumference. This is followed by immediate elastic retraction of the flap-angle thus freed, but owing to the fact that the stitches are already correctly placed, approximation must be perfect. The sutures should be tied first either at the center or the inner canthus. The stitches are removed on the third day. Occasionally one will be found to have cut through, but no damage is done. The operation must be thoroughly aseptic. He claims that this operation leaves the eye in a nearly normal condition without danger of relapse, that post-operative reaction is very mild, and that it is applicable to all cases except where the pterygial body is very wide and no tissue for approximation is available. In such cases transplantation is the only resource.

72. **Enophthalmos and Tenon's Capsule.**—From a study of the anatomy of the eye, Shoemaker thinks it probable that the orbital fascia is necessary to maintain the eyeball in its natural position, and if it becomes incapable of performing its function then enophthalmos may result. This may be the case in paralysis of the muscular fibers in the check ligaments or in nutritional disturbances leading to atrophy or relaxation of the same, which may be caused by traumatic rupture of the check ligaments or orbital tumors of the fascia, and would be especially liable to follow rupture of the posterior investing sheath of the eyeball. The combined and simultaneous action of the four recti muscles, which rarely occurs, producing spastic enophthalmos, would meet with a physiologic protest, but not with prohibition on the part of Tenon's capsule. The elasticity of the fascia may be reckoned upon in those cases of enophthalmos said by some to follow a combined paralysis of the two oblique muscles.

73. **The Nose in Ocular Affections.**—Blaauw calls attention to the importance of knowledge of the nose for ophthalmologists and the method in which nasal disease may affect the eye with a changed secretion, with narrowing of the lachrymal duct, nervous irritation, etc.

74.—See abstract in The Journal, xxxiv, p. 688.

80. **Syphilis of the Uveal Tract.**—In seventy cases of syphilis, Vaughan finds the uveal tract involved twenty-nine times, or in 41.4 per cent. Twenty-one of these twenty-nine were cases of iritis or cyclitis, the left eye predominating. Hypopyon existed in two of these cases, eight and five years after the infection, respectively. His experience accords with that of Schmidt-Rimpler, that in iritis with the formation of nodules, as a rule, true gummata are not present, and he includes in his syphilitic cases all that occurred after infection but responded to specific treatment. The symptoms vary very little from iritis due to other causes. Syphilitic choroiditis is always exudative; he has never seen a purulent case that he could attribute to this cause, and as regards syphilitic chorio-retinitis, he thinks the process generally primarily involves the choroid and that the retina is only secondarily involved.

81. **Scopolamin and Atropin.**—From thirty cases selected from private and dispensary practice, tested with scopolamin and atropin to ascertain the relative action of the two, Rogers finds that the results of scopolamin contrast unfavorably with those of atropin. In only one of the thirty did both eyes show the same refraction under each drug. He concludes that as a final reliance scopolamin is untrustworthy.

82. See paragraph 103.

84. **Anesthetics.**—Levers gives the details of administration, favoring chloroform, and offers the following conclusions: 1. In most cases chloroform is to be preferred to ether, as it is more pleasant to patient, the after-effects are less marked, and we believe, if statistics were accurate, it would be equally as safe as ether. 2. Where possible, the patient should be prepared for the anesthetic. 3. One of the most important and successful steps in the administration of an anesthetic is to secure the full confidence of the patient. 4. The anesthetist should not be made nervous by the surgeon's suggestions. 5. Chloroform should be given slowly, with plenty of air, by the "drop-by-drop" method.

89.—See abstract in The Journal, xxxiv, p. 1491.

95. **Fireman's Cramp.**—This disorder is but little mentioned in journals or text-books, but it is, according to the author, a very real one to the workers in the fire-rooms of steamers. The sufferers generally undertake their duties when in a deteriorated condition from shore excesses and are subjected to the most serious conditions of temperature and exposure otherwise. Cummings, finding the stock remedy for this disorder to be something akin to "sun cholera mixture," he sought for a substitute which could be freely used without leading to gastric and bowel disturbances. The one he devised consists of the following prescription: 256 gr. each of calcium, sodium and potassium phosphates in one gallon of water, with an excess of ortho-phosphoric acid. For the use of nine men in four hours, 6 ounces was put up in nine gallons of water containing oatmeal and ice, if available, each man drinking appproximately a gallon of water during watch, which would give about 3.5 drams of phosphate solution per man. The effect was immediate, and "phosphose," as they called it, was in daily demand. It was observed during the time of its continuous use that the men would not use it occasionally for several watches; when asked why, they said that they didn't feel the need of so much of it, as what they had already taken had braced them up sufficiently. He claims, by the use of this mixture, he has relieved colic and cramp and stimulated a natural desire for food and in consequence that he got more and better work from a class of men whose labors and pains are but little understood by those who know only the saloon-deck life of the sea.

96. **Amelia.**—Ballantyne reports the result of examination of a kitten in which the right forelimb was absent, and reviews the reports of others who have observed the condition of the cord in some instances in the human subject. The conclusions to which he comes are largely negative. If the changes in the spinal cord are absent, this can not be said to prove that the absence of the limb is due to arrested development of the central nervous system, or an atrophic center does not prove that arrested development of the cord is the cause of this deformity. The third theory is that the pressure of the amnion over that part from which the limb springs causes complete or partial lack of development. This theory also is not absolutely supported. His study of the question leaves it in the following state: In some cases, absence of the limb may be due to, or associated with, defective development of the corresponding part of the spinal cord. In other cases, pressure from the amnion often prevents the growth of the limb or a part of it, therefore causing injury in the cord, and in yet other cases, especially in the absence of one or more digits, the defect may be due to amputation of the parts by amnion bands or other agencies *in utero*, and the changes in the cord be secondary.

97. **Secondary Syphilis.**—According to Frick, secondary syphilis should be classed with eruptive fevers. The importance of being able to recognize secondary eruption is shown by considering the fact that it is frequently the first intima-

tion of the disease, the primary sore having been too obscure to be recognized. This is the specially contagious period of the disease and the period for active treatment. Macular eruptions are usually the earliest manifestations of secondary symptoms, and he calls attention to the importance of condylomata lata as a diagnostic feature. The mucous patch comes near being a constant factor and is sometimes difficult to control. He has had serious trouble with syphilitic paronychia. Mercury must be our sheet-anchor in this stage, but must not be pushed to the patient's disadvantage. Where patients can not use the drug internally, he uses inunctions, also Turkish baths. He does not like the hypodermic method, and would not use it except where a very rapid effect of the drug is required. Frequently a good tonic is of benefit along with the mercurial treatment. Iodids are not indicated until very late in the secondary stage.

98. **Insolation.**—Simpson describes the symptoms of thermic fever, which is common in children, of heat prostration which may or may not have a high temperature, and of true insolation, or sunstroke. In the first-named rapid stimulants which act on the skin will suffice to establish the equilibrium. Caffein. ammonia, champagne, cool cloths to the head and something cool to drink will soon set the patient right. The digestive disturbances need not be seriously regarded. Practically the same holds good for heat prostration. A cold douche to the head followed by ice-cloths, cool sponging and some rapid stimulant will usually be sufficient. Drugs may be given subcutaneously if necessary. There are occasionally cases of meningitis following such attacks, but it is not certain they are caused by them, as they may have pre-existed. The most disagreeable effects of heat prostration are usually neurasthenia and hysterical symptoms. True sunstroke, however, is different; it almost always leaves defects. The treatment is substantially the same as that of the other forms, only more urgent and thorough. He does not believe in bleeding or transfusing sunstroke patients. When the patient is placed in bed, he must be watched, and when the temperature has been reduced to 102 or 103 F., the necessity for further reduction is not great, and should be proceeded with judiciously. As soon as the return of consciousness and respiration is established, the danger of immediate fatal issue is over. Judicious stimulation should be administered. After consciousness has returned the patient must receive the same care as a patient suffering from severe febrile disease. The urine and perspiration must be watched. Bad results may come later.

100.—This article has appeared elsewhere. See The Journal of August 4, title 81, p. 319.

103. See paragraph 82.

104. **Drainage of the Abdominal Cavity.**—The literature of drainage of the abdomen is reviewed by Sharpe, who considers that it is definitely and positively indicated in selected cases, such as special gall-bladder conditions, weakened intestinal walls, intestinal suturing of special character, and various other pathologic states. He thinks that, however, as a routine policy it is capable of great restriction by permitting our technique to be governed by a series of rules in accordance with these suggestions: 1. Better protection of non-infected areas. 2. Better cleansing of infected areas. 3. Better covering-in of raw surfaces. 4. Better hemostasis. 5. Greater attention to details of operative asepsis. 6. Greater gentleness and skill in operative technique.

113 and 114. **The Watery Extract of Tubercle Bacilli in Phthisis.**—Osborne has followed Von Ruck's method of treatment in tuberculosis with, as he thinks, great advantage. He believes the superiority of true tuberculous substance in the form of watery extract is attested by unmistakably better results in clinical employment as well as in the animal experiments of Von Ruck. In a letter following Osborne's paper, Von Ruck argues that antitoxins are ineffective in phthisis, since the symptoms of the disease are not due to absorption of the bacillary toxins. He thinks, therefore, that since the symptoms in all stages of the disease react to these latter, this is evidence in favor of his view. He holds also that the direct injection of toxins produces immunity and is therefore justified from a therapeutic point of view.

119. **Stenosis of the Pylorus.**—Bettmann criticizes the surgeon's idea of stenosis of the pylorus, that it occurs so frequently and just so often requires operative interference. Medical experience, he thinks, does not bring out these conclusions, and an appropriate abstinence treatment and enforced rest would, in many cases, have as efficient effect as the operation itself. The subject, he believes, is not sufficiently treated in text-books.

122. **Corneal Ulcerations.**—The general principle of the treatment of corneal ulcers, of which Tennent gives the various types, is to begin treatment, especially in acute cases or in strumous children, with a mercurial. Find out the cause. In children and most adult cases internal medication is more important than local measures. Mercury has the widest application internally and next to it tonics and reconstructives. The local measures consist in: 1, preservation of cleanliness; 2, relief of pain; 3, application of mildly stimulating remedies; 4, scraping with an application of stronger stimulants and antiseptics; 5, cauterization.

123. **Laryngeal Phthisis.**—The treatment recommended by Cheesborough for this condition consists in first watching the general health of the patient, giving tonics and digestants when necessary, and large quantities of nourishing and easily digested food. Well-directed exercise and plenty of fresh air in a suitable climate should be insisted upon. Creosote he holds of value in every case of tuberculosis when carefully and properly administered. Begin with a few drops and increase the dose daily until the patient begins to suffer from some gastric disturbance, then go back to the small doses and gradually increase again. Nearly every patient can take creosote thus administered. For local use he employs alkaline and antiseptic washes to thoroughly cleanse the nose and throat, following these by inhalations of glymol with menthol, and ether or iodid and ether, or other drugs found to be soothing, and an anodyne for checking the cough. In a certain percentage of cases the curette and lactic acid are necessary. His method is to first curette and begin with a 3 per cent. solution of lactic acid, gradually increasing its strength as required. It is often necessary to use local anesthetics when curetting. Laryngotomy, laryngectomy and tracheotomy should be limited to only the most exceptional cases.

127. **Static Electricity.**—Lowder claims great success with static electricity in neuralgia and headache, using a sort of general electrization. He claims that he has cured about 85 per cent. of his selected cases. For rheumatism he relies almost altogether on electricity and in painful menstruation he has never had such beneficial results from any other remedy. Other disorders which he claims to have successfully treated in this way are insomnia, amenorrhea, malaria, incipient colds, senile debility, bronchitis, gastralgia, cardiac disorders, heat prostrations, etc.

FOREIGN.

The Lancet, August 25.

Pathology and Therapeutics of Scurvy. A. E. Wright.—In defense of the theory formerly maintained by him that scurvy is a condition of acid intoxication with deficient alkalinity of the blood, Wright undertook a series of blood examinations and therapeutic experiments on cases which came under his control in the Army Hospital at Netley. The normal alkalinity of the blood is such that the addition of one volume of normal acid thirty-five times diluted to an equal volume of serum just suffices to deprive that serum of its power of blueing sensitive litmus paper. Seven cases of marked scurvy were tested and in each case the alkalinity of the blood was found strikingly reduced, and in all, excepting in one where there was reason to suppose that the drug was not dissolved, a decided amelioration followed the administration of lactate of soda and other similar substances. Certain subsidiary points were also noticed. In three of the cases there was a dysenteric complication, but this differed from the ordinary dysentery in its clinical features and also in the fact of reduced alkalinity of the blood. In one of the cases it appears that the scorbutic conditions could supervene and complicate typhoid fever.

The Pathogeny of Gout. Dyce Duckworth.—The pathogeny of gout and its theories are discussed by Duckworth, who sums up his own conceptions in regard to it as follows: "That gout as a morbid condition, depends on an inherent vice of nutrition, which is manifested by an imperfect metabolism in various organs or parts of the body, presumably in the kidney and probably in the liver. That this trophic disorder or inadequacy—*ralentissement de nutrition*—leads to the formation of uric acid, probably in excess, and to the periodic retention of it in the blood—gouty uricemia. That histology throws no light on the intimate nature of this defect, which thus relates to cellular potentiality, possibly under neurotrophic influence, and not, so far as we know, to structural alteration. That this textural disability, or a tendency to it, may be primarily acquired and also transmitted as a fault, thereby inducing from time to time uricemia with gouty manifestations in the descendants. That in most instances, under conditions which provoke it, and in some cases independently of these, attacks of gout may grow up and come to a crisis. Such crises are attended by an alteration in the solubility of the uratic salt in the blood, whereby irritating crystals of biurate of sodium are produced and precipitated in various parts of the body. That a paroxysm of gout, the sites of its occurrence, and its metastases are determined by nervous influences, probably dominated from a bulbar center, and that the local attacks alight either in the joints or in textures which have been weakened or rendered vulnerable by impaired nutrition owing to past injury or over-use. That this central neurosis is an essential and transmissible feature in the pathogeny of gout and pertains to the arthritic diathesis generally. That the uricemia of gout is peculiar and unlike that which is induced by other morbid conditions, but that the occurrence of uricemia in the gouty is by itself inadequate to induce attacks of gout. That uratic deposits may occur to an enormous extent in gouty persons without the occurrence of any pain or paroxysms. That the clinical features of gout indicate that both hemic changes—due to inherent morbid tissue metabolism —and a neurotrophic disturbance act as pathogenic factors, and that consequently gout is to be regarded as a neurohumoral malady."

Diphtheria in the Horse. Louis Cobbett.—The author examined the cultures of the bacillus found in a nasal discharge of a pony, which appeared to be entirely identical with that of diphtheria. The animal had purulent, slightly sanguineous, nasal discharge, subsequent enlargement of the glands under the tongue, laryngeal obstruction, difficulty of breathing and contraction of the abdominal wall. He concludes from his study of the case that the horse is liable to nasal and laryngeal diphtheria, and that this is of practical importance since it points out a hitherto unsuspected channel of conduction of the disease to man. It also has a bearing on the question of the origin of antitoxin. It is well known that the serums of normal men and horses which have never been immunized often have the power of neutralizing diphtheria toxins and it is shown, in the cases of horses at least, that this defective serum unites with toxoids as well as with toxins proper, just as does the serum of immunized animals, that, in a word, it contains true antitoxin. The diphtheria antitoxin found in many is probably due, as Wassermann has suggested, to some previous attack of diphtheria, possibly not recognized, and that found in the placental blood of infants may have been due to the mother having had the disease. Now that we find the horse is subject to diphtheria, the presence of antitoxin in its blood-serum is easily explained.

Enteric Fever. Derwent Parker.—The author gives his experience with 100 cases of enteric fever treated by him in South Africa. One of the first points noted is the great difference in the virulency of the attack according to the district from which it comes, those from certain regions having been almost all of severe type, while the later cases, no matter where they came from, were milder than those of earlier date. The most severe cases were infinitely worse than any he had seen in England. One patient had seven distinct perforations, and two, had they lived longer, would have had even more, as every Peyer's patch in the last few feet of the small intestine was gangrenous. The hospital was situated at an elevation of 4500 feet and was made up of tents with excellent ventilation. Lung complications, however, were very rare. All the patients took 5 minims of carbolic acid in water three times a day. He found that to some extent carbolic acid appeared to have a tendency to increase the frequency of hemorrhage, but on the whole he thinks its effects are good. Apparently brandy was the most useful stimulant. Transfusion with normal salt solution he thinks, can save a great many lives in cases of severe hemorrhage. From his studies of the effects of inoculation he finds the death-rate among the inoculated 2 to 3 per cent. lower than that of the non-inoculated, and while, the average temperature for the first ten days was 0.9 per cent. lower, it was 5.4 days longer before becoming normal. He does not consider inoculation as at present practiced a striking success.

Janus (Amsterdam), August.

Organotherapy, Past and Present. H. Grasset.—The question of internal secretions is intimately connected with that of organotherapy, but no one seems to comprehend the important relations between the soluble ferments and these questions. A. Bechamp has explained the transition between the medical traditions of the ancients in respect to organotherapy and the facts discovered, but erroneously interpreted, by modern bacteriologists. He asserts that the cell is not the organic vital unit. It is, according to him, an association of autonomous and independent organisms, which he calls "microzymes." Each secretes its soluble digestive ferments or zymases, which allow it to modify the medium in which it lives, and assist in its absorption, assimilation and growth. Each zymase characterizes the physiologic function of the microzyme in the cell and in the organ, the function varying with the species of the animal and the age of the individual. Grasset accepts this theory and adds that these soluble ferments are excessively fragile; the slightest cause destroys them. Chemical or physical manipulations injure or kill the vital principles in the organs and hence the present methods of extraction for therapeutic purposes are all defective.

Annales de l'Institut Pasteur (Paris), July 25.

Sero-Agglutination in Pneumococcus Infection. F. Bezancon and V. Griffon.—The Widal agglutination test is not applicable to pneumococcus infection, as the phenomenon is not sufficiently marked to be evident in diluted serum. But with cultures of the pneumococcus in non-diluted serum the reaction becomes very distinct. Tests on 186 persons demonstrated, however, that the serum agglutinates most decidedly, and in some instances exclusively, the pneumococci derived from the individual lesion. This individuality in respect to the agglutinating reaction which has been established for the pneumococcus and bacillus coli, throws light on the disputed question of the unity or plurality of streptococci. The serum of animals vaccinated against the streptococcus seems to have real preventive or curative action only against the special streptococcus that served for the vaccination.

Influence of Tetanus Toxin on Central Nervous System. M. Joukowsky.—The only modification in the nerve-cells constantly noted in this experimental research in Metchnikoff's laboratory was an accumulation of migrating, mononuclear cells around the nerve-cells and their penetration into the protoplasm of the latter. The phenomenon was most marked in the anterior horns and most intense in chronic intoxication. It is probably the expression of the mononuclear phagocytosis which develops under the influence of the toxin in the nerve-cell and is a sign of diminishing cell vitality.

Bulletin de l'Academie de Medecine (Paris), August 14.

Physiology of Cervical Sympathetic. T. Jonnesco and T. Floresco.—Applying to man the technique of experimental research, the Bucharest scientists have established the identity of the functions of the cervical sympathetic in man and in animals. Their subjects were patients on the point of having sympathectomy performed. The member of the Académie who presented their article in a condensed form, remarked: "It is not without a certain emotion that one follows the authors in the recital of their experiences, and imagines the patient under the influence of choloroform, undergoing the various operations performed for experimental purposes on the cervical sympathetic and its ganglia, with graphic exploration of the heart action and respiration, and of the pulsation of the exposed brain. If the results attained prove to be valuable beyond dispute and do not require confirmation, one must not criticise the authors unfavorably for the hardihood of their attempts. At least they had no serious consequences for the patient, such as follow experimental, direct, electric stimulation of the brain, and consequently can not be condemned, as the latter justly is." The research demonstrated that stimulation of the superior stump of the sympathetic after resection produces the same effects as stimulation of the intact nerve. The vasoconstrictive action of the sympathetic on the brain was also demonstrated, and the fact that weak stimulation has the opposite effect, i. e., the smaller vessels are dilated, similar to the influence of the same nerve on the superficial circulation. When the heart has been accelerated by stimulation of the sympathetic, it is not retarded by the section of the nerve. Injection of pilocarpin induces sweating on the sound side but not on the operated side after section of the sympathetic and subsequent degeneration of the sweat fibers. The most important result of their research is the demonstration that no appreciable nutritional modifications occur in the regions innervated by the resected nerve. This latter statement needs confirmation. Surgeons should take special pains to follow their patients after sympathectomy to note whether there is deterioration in the functional activity of the brain and ocular apparatus.

Herpes in Infectious Diseases. E. Vidal.—By the term "herpes" Vidal expresses the attempt of the tissues to eliminate foreign bodies, whether it takes the form of an eruption on the skin or a morbid process in some internal organ or tissue. This manifestation is especially characteristic of la grippe. The bacillus penetrates into the organism by some unknown means; the struggle begins, fever lights up, the organism tries to expel the foreign bodies and the cycle is completed by the herpetic eruption within or without. This eruption produces solutions of continuity and any secondary germs which may happen to be in the vicinity find an easy entrance through them into the tissues. If the herpetic eruption happens to be in the lungs, for instance, and the pneumococcus is present, secondary pneumonia is liable to develop, as the germs invade the capillaries, with possibly further infection by them of the arteries, peritoneum, kidneys and spleen. "This conception explains many otherwise inexplicable problems in infectious processes, their successive localizations on different organs, recurrences, etc., and should be accepted until the contrary is proved."

Antisepsis for Contagious Diseases With Only Partial Isolation. Grancher.—The results obtained by Grancher in a medical ward at the Hôpital des Enfants during the last ten years—in comparison with the preceding ten—confirm his assumption that contagion is seldom if ever air-borne, but occurs solely by direct contact. The ward is frequented by students, is in an old building, and children with measles, diphtheria, scarlet fever, whooping-cough, bronchopneumonia and mumps are received indiscriminately, but contagion from one to the other is extremely rare. In ten years there has only been one case of diphtheria, scarlet fever or mumps from this cause, seven of whooping-cough and 1 to 3 per cent. of all the cases of measles. The latter is the most difficult disease to manage, as contagion may occur before the diagnosis is possible. He treats a patient with one of these infectious diseases as he would a wound, and applies antisepsis in the same way, with partial isolation. A lattice-work screen, about four feet high, is placed around the bed, entirely enclosing it. This prevents contact between the children and reminds the attendants that certain precautions are necessary before entering the enclosed space. These precautions are to put on a blouse, which is kept permanently in the "box," and to wash the hands with soap and a 1 per cent. solution of sublimate. All the dishes used by the child are disinfected with boiling water, while the bedding and dismounted bed are sterilized in the oven. The paraffined floor and the walls are washed off twice a week with the same solution of sublimate. This idea that contagion is objective and not atmospheric, and that it can be controlled with antisepsis, should dominate in the care of all hospitals for children.

Revue de Gynecologie (Paris), July-August.

Study of Autoplastic and Temporary Sutures. L. Dartigues.—After reviewing the various methods, Dartigues asserts that temporary sutures best fulfill the condition for noninfection of the wound in operating for hernia, the incision as short as possible, extensively freshening the rectus muscles and suturing the inner margins together, and above all, securing perfect hemostasis. For esthetic reasons the suture should be as low and as intradermic as possible. He commends Segond's practice of combining an autoplastic suture of the deep tiers, with a couple of figure-eight silk sutures above, and a superficial suture of silver wire. The figure-eight stitch is especially useful for hysteropexy. Among the forty-one illustrations are two portraying the old corkscrew method, showing the corkscrew inserted to close the inguinal wound, burrowing through the deep tissues and removed as the wound healed. It crudely answered the purpose of the modern metallic, removable sutures.

Remote Results of Abdominal Hysterectomy for Cancer of the Cervix. C. Jacobs.—Every one of 70 patients with cancer of the uterus, treated by vaginal hysterectomy, died of recurrence within a few months; only two survived as long as two years. On the other hand, out of 52 abdominal hysterectomies 13 are still alive without a trace of recurrence—several operated on more than twenty-seven months ago. The recurrence in the rest was torpid and comparatively painless. Jacobs urges immediate intervention if on several occasions the cells in the vaginal or glandular secretions are found enlarged, irregular and granulated, isolated or connected by strips of newformed tissue. He never performs hysterectomy unless convinced that the lesion is restricted to the uterus. He removes the organ in two portions after severing the ovarian arteries, dividing it above the internal orifice and thermocauterizing the cavity of the cervix before proceeding.

Pulmonary Embolism After Fibromectomy. G. Michel.—Postoperative thrombosis may be feared in women exsanguinated by repeated metrorrhagias induced by a large fibroma compressing the organs in the small pelvis. The thrombosis may be in the pelvic veins, in which case the absence of valves renders it generally fatal. Only three cases of pulmonary embolism from this cause have been known to recover. There are 13 deaths on record from pulmonary embolism consecutive to the removal of fibrous tumors of the uterus, out of a total of 568 abdominal or supravaginal operations, and seven deaths in 209 vaginal. The heart is usually degenerated in these patients, and, as it is unable to overcome the obstacle in the circulation by stronger contractions, can only accelerate the beat. The rapid pulse in contrast to the normal temperature is the sole sign of a hidden thrombosis. Before undertaking any gynecic operation the vascular system should be examined. If the veins are hard and painful, the pulse rapid, with more or less edema of the lower limbs, intervention should be postponed if possible, until conditions are more favorable.

Centralblatt f. Bakteriologie (Jena), July 11.

Experimental Research on Rabies. V. Solomon.—Galli-Valerios recommends inoculating animals with rabies on the nasal mucosa as the most effective method and the least dangerous for the operator. Leclainche's intracranial method is also exceptionally effective. Both normal and pathologic bile have a neutralizing influence on the virus of rabies.

Centralblatt f. Inn. Med. (Leipsic), July 14.

Urotropin in Cystitis. B. Goldberg.—The experiences described suggest an explanation for the contradictory results attained by others with urotropin in the treatment of cystitis. Goldberg found that 40 per cent. were cured and all the rest materially improved in his 54 cases of cystitis due to primary bacterial invasion of healthy organs. It also proved effective when the cystitis was consecutive to other affections if combined with other measures. But it was useless in secondary cystitis with ascending infection or incipient urinary intoxication.

Acute Effusions in the Pericardium. F. Aporti.—A series of tests on cadavers showed that it is impossible to detect a pericardial effusion by percussion if the amount is less than 150 to 200 c.c. The maximum amount that can collect is 650 to 700 c.c. In a horizontal position the area of cardiac dulness spreads out in all directions, the large vessels are bathed in fluid, even with a small amount, but when the body is erect, the base of the heart is free with the maximum of accumulated fluid.

Deutsche Medicinische Wochenschrift (Leipsic), August 16.

Aneurysm Cured by Electrolysis of an Introduced Wire. A. Bernheim.—Our Philadelphia colleague describes another case of an extensive aneurysm of the aorta cured with the introduction of fine gold wire and electrolysis. It is the fifteenth instance of this treatment on record and is distinguished by the fact that the operation was repeated three times in a few months before the cure was permanent. Four of the fifteen cases were very much improved, five were cured and all relieved by the intervention—results which should encourage its further application. In the experience reported nearly nine feet of a spirally coiled fine gold wire were inserted, and the anode applied, with the cathode on the back. A current of 10 to 80 milliamperes was turned progressively on and off during one hour. The sac slightly contracted and the pulsation diminished even before the operation was concluded. The results of the intervention were examined with an exploratory puncture two months later and about the same amount of wire introduced again, and half this amount thirty-nine days afterward. The patient was dismissed four weeks after the last intervention and has resumed his business as a commercial traveler.

The Tubes in Roentgen Ray Therapy. Straeter.—In the therapeutic application of the Roentgen rays, the "soft" tubes should be selected for superficial pathologic processes, and the less "soft" for the deeper lesions. Very "hard" tubes are unsuitable for Roentgen therapy.

Is the Action of Alcohol Nutritional or Toxic? Kassowitz.—The well-known Vienna professor presents numerous arguments to prove that it is impossible for a substance to play the dual rôle of a food and a toxin at the same time, and that alcohol in particular never possesses nutritional, but always and exclusively toxic, properties.

Memorabilien (Heilbronn), July and August.

Infarct of the Lungs. C. C. Rothe.—A healthy young man was being treated for a phlegmon of the thigh, which had developed subsequent to exposure, and spread to include nearly the entire thigh, with symptoms of cardiac insufficiency. He was progressing favorably by the twelfth day, but succumbed the seventeenth to an embolism in the lungs, evidently originating in the veins of the thigh. In another patient a fatal serous effusion filled the right thorax in the third week of a mild abdominal typhoid fever. A second case of typhoid pleuritis was marked by the absence of an effusion and the evidences of thrombosis in the lungs, evacuation of drops of dark blood by puncture, etc. It terminated in recovery.

Mittheilungen a. d. Grenzgebieten der Med. u. Chir. (Jena), vi, 1 and 3.

Infusions of Salt Solution. Leonpacher.—Summarizing the experiences in 100 cases treated with infusion of salt solution, Leonpacher states that the effect was favorable but transient in 8 cases of severe burns, all terminating fatally. The anuria was not influenced by the infusion. The amount found most beneficial in acute anemia was 1000 to 1500 c.c. at 40 C., repeated several times. For chronic losses of blood, 500 c.c. at 40 C. were injected every day for a long period. The same amount was injected in collapse after operations and long narcosis. In septic affections 1000 to 2000 c.c. were slowly injected at body temperature. The effect is chiefly stimulating in this case. Local injections of 8 to 10 c.c. were made in five cases of ulcus molle. The ulcus progressed to superficial suppuration and rapid retrogression in eight to ten days in 2. In 2 others it retrogressed in fourteen to twenty days without suppuration. The fifth was a hard, indolent bubo and was only temporarily improved.

Recurrences After Gall-Stone Operations. A. Hermann.—In Hermann's experience as superintendent of the hospital at Carlsbad, he has observed eleven cases of unmistakable recurrence of biliary calculi after a successful operation from eight months to three and one-half years previously.

Carcinoma of the Skin Cured With the Roentgen Rays. Thor Stenbeck.—A healthy woman of 72 years applied for relief from a typical ulcus rodens which had been slowly developing on the nose during ten years. As she shrank from an operation, Roentgen treatment was first tried. The ulcus suppurated freely at first and then healed over in the course of thirty-five sittings, although a month more was required to banish the last traces of the neoplasm.

Experimental Contribution to the Study of Cholelithiasis. H. Ehret.—Normal bile in guinea-pigs, cattle and dogs is by no means sterile. Microbes were found in the bile of nearly every animal examined. They probably make their way from the intestines through the biliary passages. Isolated germs occasionally find their way into the bile from the circulation, but these are exceptional cases and the microbes in the bile are a manifestation of pathologic processes.

Laparotomy in Case of Tubercular Peritonitis. A. Borchgrevink.—After twenty years of special clinical and experimental study of this subject, Borchgrevink states that in the healing process the shriveling nodule becomes transformed into a loose network of fine fibers. This is gradually absorbed and the tubercle vanishes as completely as any other ordinary granulation tissue after a transient, harmless irritation. This primary healing of the tubercle, as he calls it, is of frequent occurrence in ordinary peritoneal tuberculosis unaccompanied by caseous foci. Serous tubercular peritonitis, with slight or no fever, recovers spontaneously by this mechanism, and laparotomy is superfluous. On the other hand, laparotomy is distinctly injurious in the progressive cases with continuous fever. Laparotomy should therefore be rejected in all cases. Puncture at the right moment is fully as effective. As long as the tubercle is keeping the peritoneum irritated no operation has any curative effect, but when the healing has reached a certain stage laparotomy or puncture are both equally effective.

Experimental Antiperistalsis. R. Muehsam.—A long portion of the small intestine was resected in some experiments on a couple of large dogs and, sutured in place, reversed. The results showed that the reversed intestine was able to make peristaltic movements in the direction contrary to its natural peristalsis sufficiently vigorous to propel the food along, although vomiting occurred at times, evidently from return to its natural peristalsis. In one of the animals the natural peristaltic movements were so vigorous that the upper transplanted end became invaginated in the normal distal intestine.

Monatschrift f. Geb. u. Gyn. (Berlin), July.

Uterine Calculi.—The report of the meeting of the St. Petersburg Medical Society describes several specimens of uterine calculi exhibited or cases described. In one the uterus was entirely filled with stones the size of a bean to that of a walnut. In another, multiple myomata had become "petrified" from the same cause. A fibromyoma in another case was full of a purulent fluid, the walls lined with calculi in the form of scales. A specimen in the Kazan museum was mentioned in which the petrifaction is as hard as granite.

Muenchener Medicinische Wochenschrift, August 31.

Prevention of Pneumonia After Laparotomies. G. Kelling.—Pneumonia consecutive to laparotomies in the upper abdomen may be due to infection from germs in the air, which may find their way under the diaphragm and thence into the lungs. To prevent this Kelling has studied to reduce the number of germs in the air as much as possible. His operating-room is large and the windows open on a green garden, instead of on the street. The room is heated from without. The heating apparatus does not draw its air from the room, as this would aspirate a fresh supply through the crevices. All windows are closed four hours before an operation, after the walls and floors are dampened. As soon as the abdomen is opened the cavity is stuffed with gauze to prevent the entrance of air as far as possible. The floor is kept wet, the operator and assistants wearing rubbers. Entrance is through a small anteroom with double doors. Operating is not so agreeable under these circumstances to the surgeon, but his inconvenience is far outbalanced by the entire absence of postoperative pneumonia. He had five cases occur in the corresponding period in an equal number of patients the year before he fitted up this room.

Sugar to Increase Uterine Contractions. M. MADLENER.—In three of the six cases in which the writer has employed sugar to increase the energy of the contractions of the uterus, the pains were much diminished, while the contractions were increased. The latter effect was evident in all but one, and he recommends the general use of sugar for this purpose as simple, harmless and effective.

Wiener Klinische Wochenschrift, August 9 and 23.

Total Exclusion of the Intestine. E. PAYR.—An erosion of the intestine in consequence of a deep suppurating process in the abdominal cavity demanded that the communication between the cecum and the abscess cavity should be shut off. The condition of the patient contraindicated total exclusion, and an ileocolostomy was done, the ends of the intestine closed with a circular seromuscular drawn thread. After a few days of apparent success fecal matters were discharged through the fistula. Analysis of similar cases in the literature shows that fold-sutures, draw-strings and ligatures are extremely unreliable as means of closing the ends of a section of intestine. It is far from certain that the closing of fecal fistulæ, spontaneously or with slight operative assistance, is any guarantee that the morbid process is positively terminated, unless the inside is cauterized. The cases in which the secretion in the excluded portion seems to have completely ceased, with no previous cauterizing or antiseptic measures, will be found in most instances to be due to occlusion of the fistula, while the secretion continues accumulating in the depths, even in case of a normal intestine, and there is always danger of an outbreak. In many instances the total, blind exclusion is only apparent, and in reality secondary adhesions and perforation allow the escape of the secretions. In a case of Hochenegg's a mass of fecal matters was suddenly evacuated from the supposed excluded portion, fourteen months after operation. Of the thirty total exclusions noted in the literature, two only succumbed at the time of operation. Experience with intestinal diverticula, etc., confirms Payr's dictum that the complete exclusion and blind closure of a portion of the intestine is liable to induce pathologic changes.

August 23.

Treatment of Epilepsy. M. BIRO.—Eight years of observation of the results of treatment of 185 epileptics have convinced Biro that the bromids are the best general therapeutic measure, but if they fail, Flechsig's method should be tried, resorting later to Bechtereff's, atropin or a combination of bromids and antipyrin. He comments on the periodicity in the recurrence of the seizures.

Gazzetta degli Ospedale (Milan), August 19.

Occlusion of Biliary Passages by Hydatid Cyst. L. FERRALASCO.—The hydatid cyst in the case in question had developed insidiously in the liver until it had perforated into the biliary passages, with occlusion and dilatation of the ducts from the remnants of the cyst. This had induced circumscribed purulent angiocholitis and laceration of the liver with fatal hemorrhage.

Cronica Medica (Lima), June 30.

Diazo-Reaction in Microbian Diseases. E. E. ESCOMEL.—A study of Ehrlich's diazo-reaction in eighty patients showed that the test resulted positively only in miliary tuberculosis, tubercular meningitis, typhoid fever or typho-malaria, smallpox, erysipelas and the last stages of pulmonary tuberculosis. It was invariably negative in malarial and rheumatic affections. The positive result of the diazo-reaction thus excludes certain diseases and is a valuable aid in the differentiation of typhoid fever.

St. Petersburger Medicinische Wochenschrift, August 18.

Symptoms and Treatment of Disorders Due to Trichocephalus. T. HAUSMANN.—Microscopic investigation of the feces should become a routine measure in all dubious cases and rank with the analysis of the urine. Many affections now classed as rebellious hysteria or gastric catarrh would disclose their true etiology if this were done, and would respond promptly to appropriate measures. Hausmann requests the patient to bring him a little of his feces, preferably of soft consistency, in a liqueur glass. A scrap is transferred to an object glass with a toothpick; a drop or two of glycerin is added, if hard, and a cover-glass placed over it and rubbed around a little. Eighty-five diameters is sufficient at first, increasing the magnifying power if suspicious objects are noted. The symptoms caused by the trichocephalus are manifold and simulate many affections; the only specially characteristic sign is extensive cutaneous anesthesia occasionally noted. In one of the instances he cites, a young and healthy man became emaciated, constipated, with abdominal pain and impotentia coeundi, diminished reflexes and other symptoms, becoming progressively worse as the months passed. Three days of thymol—prescribed after the eggs of the trichocephalus were found in the fecal matters—restored him to complete health, but the cure was repeated not long after as a precautionary measure. Thymol seems to have a specific action against this parasite, far more powerful than santonin or other remedies.

Books and Pamphlets.

Acknowledgement of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interests of our readers.

BOOKS.

INTERNATIONAL CLINICS. A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattell A.M., M.D., Director of the Ayer Clinical Laboratory of the Pennsylvania Hospital, with the Collaboration of John Ashhurst, Jr., M.D., LL.D.; Charles H. Reed, M.D.; and James T. Whittaker, M.D., LL.D. With Regular Correspondents in Montreal, London, Paris, Leipsic, and Vienna. Volume II. Tenth Series. Cloth. Pp. 300. Price, $3.00. Philadelphia: J. B. Lippincott Co. 1900.

THE RETROSPECT OF MEDICINE. A Half-Yearly Journal Containing a Retrospective View of every Discovery and Practical Improvement in the Medical Sciences. Edited by James Braithwaite, M.D., Consulting Obstetric Physician and Surgeon to the Leeds General Infirmary, and E. F. Trevelyan, M.D., B.Sc., M.R.C.P., Assistant Physician to the Leeds General Infirmary. Volume 121. January-June, 1900. Cloth. Pp. 431. Price, $2.50 per year. London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd.

ATLAS AND EPITOME OF DISEASES CAUSED BY ACCIDENTS. By Dr. Ed. Golebiewski, of Berlin. Authorized Translation from the German, with Editorial Notes and Additions. By Pearce Bailey, M.D., Consulting Neurologist of St. Luke's Hospital and the Orthopedic Hospital, New York. 40 Colored Plates, and 143 Illustrations in Black. Cloth. Pp. 549. Price, $4.00. Philadelphia: W. B. Saunders & Co. 1900.

CANCER OF THE UTERUS: Its Pathology, Symptomatology, Diagnosis, and Treatment; also the Pathology of Diseases of the Endometrium. By Thomas Stephen Cullen, M.B., Associate Professor of Gynecology in the Johns Hopkins University. With Eleven Lithographic Plates and Over Three Hundred Colored and Black Illustrations in the Text. By Max Brödel and Herman Becker. Cloth. Pp. 672. Price, $7.50. New York: D. Appleton & Co. 1900.

A MANUAL OF PERSONAL HYGIENE. Edited by Walter L. Pyle, A. M., M.D., Assistant Surgeon to Wills Eye Hospital, Philadelphia. Contributors: J. W. Courtney, M.D.; George Howard F[illegible], M.D.; E. Fletcher Ingals, M.D.; Walter L. Pyle, M.D.; B. Alexander Randall, M.D.; G. N. Stewart, M.D., and Charles G. Stockton, M.D. Illustrated. Cloth. Pp. 344. Price, $1.50. Philadelphia: W. B. Saunders & Co. 1900.

A MANUAL OF CHEMISTRY: Inorganic and Organic, with an Introduction to the Study of Chemistry. By Arthur P. Luff, M.D., B.Sc., F.R.C.P., F.I.C., Physician to Out-Patients in St. [illegible] Hospital, and Frederick James M. [illegible], B.Sc., F.I.C., [illegible] the Royal School of Mines. Illustrated with 40 Engravings. [illegible] Pp. 541. Price, $1.60. London, Paris, New York and [illegible] Cassell & Co., Ltd. 1900.

ATLAS AND EPITOME OF GYNECOLOGY. By Dr. [illegible] Privat Docent of Obstetrics and Gynecology in the [illegible] Heidelberg. Authorized Translation from the Second [illegible] Enlarged German Edition. Edited by Richard [illegible] M.D., Surgeon-in-charge, Preston Retreat, Philadelphia. [illegible] Colored Illustrations on [illegible] Plates, and [illegible] Text. Cloth. Pp. [illegible] Price, $3.50. Philadelphia: W. B. Saunders & Co. 1900.

DISEASES OF THE TONGUE. By Henry T. Butlin, [illegible] and Walter G. Spencer, M.S., M.B., F[illegible] minster Hospital, Surgeon to St. Ba[illegible] Charge of the Department for Dis[illegible] Illustrated with 8 Chromo-Lithographs [illegible] Pp. 475. Price, [illegible] London, P[illegible] Cassell & Co., Ltd. 1900.

Manual of Pathology. Including Bacteriology, the Technique of Post-mortems, and Methods of Pathologic Research. By W. M. Late Coplin, M.D., Professor of Pathology and Bacteriology, Jefferson Medical College, Philadelphia. Third Edition, Revised and Enlarged. With 330 Illustrations and 7 Colored Plates. Cloth. Pp. 846. Price, $3.50. Philadelphia: P. Blakiston's Son & Co. 1900.

Psychopathia Sexualis. With Especial Reference to Antipathic Sexual Instinct. A Medico-Forensic Study. By Dr. R. v. Krafft-Ebing, o. ö. Prof. Für Psychiatrie und Nervenkrankheiten an der K.K. Universität, Wien. The Only Authorized English Translation of the Tenth German Edition. Cloth. Pp. 585. Price, $5.00. Chicago: W. T. Keener & Co. 1900.

Medical Electricity. A Practical Handbook for Students and Practitioners. By H. Lewis Jones, M.A., M.D., Fellow of the Royal College of Physicians. The Third Edition of "Medical Electricity," by W. E. Steavenson, M.D., and H. Lewis Jones, M.D. With Illustrations. Cloth. Pp. 532. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1900.

Illinois State Board of Health. Advance Notes of the Sanitary Investigations of the Illinois River and its Tributaries. With Special Reference to the Effect of the Sewage of Chicago on the DesPlaines and Illinois Rivers Prior to and after the Opening of the Chicago Drainage Canal. Cloth. Pp. 57. Springfield: Phillips. 1900.

Medical Diagnosis with Special Reference to Practical Medicine. A Guide to the Knowledge and Discrimination of Diseases. By J. M. Da Costa, M.D., LL.D., Physician to the Pennsylvania Hospital. Illustrated. Ninth Edition, Revised. Cloth. Pp. 966. Price, $5.00. Philadelphia: J. B. Lippincott Co. 1900.

Practical Uranalysis and Urinary Diagnosis. A Manual for the Use of Physicians, Surgeons, and Students. By Charles W. Purdy, LL.D., M.D., Fellow of the Royal College of Physicians and Surgeons, Kingston. Fifth Revised and Enlarged Edition. With Numerous, Illustrations, Including Photo-engravings and Colored Plates. Cloth. Pp. 392. Price, $3.00 net. Philadelphia: F. A. Davis Co. 1900.

Public Health Reports. Issued by the Supervising Surgeon-General, Marine-Hospital Service, under the National Quarantine Act of April 29, 1878, and the Act Granting Additional Quarantine Powers and Imposing Additional Duties upon the Marine-Hospital Service, Approved February 15, 1893. Vol. xiv. Nos. 1 to 52. Cloth. Pp. 2389. Washington: Government Printing Office. 1900.

Original Contributions Concerning the Glandular Structures Appertaining to the Human Eye and its Appendages. By Adolph Alt, M.D., Professor of Ophthalmology in Beaumont Hospital College, St. Louis. With 71 Original Illustrations. Cloth. Pp. 70. Price, $1.50. St. Louis: American Journal of Ophthalmology.

L'Assistena dei Pazzi nel Manicomio e nella Famiglia. Istruzioni elementari per infermieri ed infermiere. Dott. A. Pieraccini, Vice Direttore del Manicomio Provinciale di Macerata. Con Prefazione del Prof. E. Morselli, Direttore della Clinica Psichiatrica di Genova. Cloth. Pp. 64. Milano: Ulrico Hoepli. 1901.

Lessons on the Anatomy, Physiology and Hygiene of Infancy and Childhood for Junior Students. Consisting of Extracts from Lectures given at Rush Medical College. By Alfred C. Cotton, A.M., M.D. Cloth. Pp. 174. Price, $1.50. Chicago: Chicago Medical Book Co.

Clinical Examination of the Urine and Urinary Diagnosis. A Clinical Guide for the Use of Practitioners and Students of Medicine and Surgery. By J. Bergen Ogden, M. D., Instructor in Chemistry, Harvard University Medical School. Illustrated. Cloth. Pp. 416. Price, $3.00. Philadelphia: W. B. Saunders & Co. 1900.

A Text-book of Practical Medicine. By William G. Thompson, M.D., Professor of Medicine in the Cornell University Medical College, New York City. Illustrated with 79 Engravings. Cloth. Pp. 1011. Price, $5.00. New York and Philadelphia: Lea Brothers & Co. 1900.

Surgery, its Theory and Practice. By William Johnson Walsham, F.R.C.S., M.B., C.M., Surgeon and Lecturer on Surgery, St. Bartholomew's Hospital. With 483 Illustrations, Including 16 Skiagram Plates. Seventh Edition. Cloth. Pp. 951. Price, $3.50. Philadelphia: P. Blakiston's Son & Co. 1900.

Report of the Mortality Records of the Mutual Life Insurance Company of New York. For Fifty-six years, from 1843 to 1898. By Elias J. Marsh and Granville M. White, M.D., Medical Directors. Cloth. Pp. 245. New York: Mutual Life Insurance Co. 1900.

The Mental Affections of Children: Idiocy, Imbecility, and Insanity. By William W. Ireland, M.D., Corresponding Member of the Psychiatric Society of St. Petersburg. Second Edition. Cloth. Pp. 450. Price, $5.00. Philadelphia: P. Blakiston's Son & Co. 1900.

The Law and its Relations to Physicians. By Arthur N. Taylor, LL.B., of the New York Bar. Cloth. Pp. 534. Price, $2.50. New York: D. Appleton & Co. 1900.

Essentials of Medical and Clinical Chemistry. With Laboratory Exercises. By Samuel E. Woody, A.M., M.D. Fourth Edition, Revised and Enlarged. Illustrated. Cloth. Pp. 243. Price, $1.50. Philadelphia: P. Blakiston's Son & Co. 1900.

Transactions of the Southern Surgical and Gynecological Association. Volume xii. Twelfth Session, Held at New Orleans, La., December 5, 6, and 7, 1899. Cloth. Pp. 394. Published by the Association. 1900.

Transactions of the Kentucky State Medical Society. Forty-fifth Annual Session, Held at Georgetown, May 9, 10, and 11, 1900. Volume viii. Cloth. Pp. 253. Printed for the Society. 1900.

Transactions of the Medical Society of the State of California. Thirtieth Annual Session, San Francisco, April, 1900. Vol. xxx. Cloth. Pp. 610. Published by the Society.

The Microtomist's Vade-mecum. A Handbook of the Methods of Microscopic Anatomy. By Arthur Bolles Lee. *Fifth Edition.* Cloth. Pp. 532. Price, $4.00. Philadelphia: P. Blakiston's Son & Co. 1900.

Idroterapia. Del Prof. Gaetano Gibelli, Proprietario del gabinetto elettro-termo-baro-idroterapico, Milano, Via Manzoni, 50. Con 30 incisioni. Cloth. Pp. 237. Milano: Ulrico Hoepli. 1900.

PAMPHLETS.

Biennial Report of the Board of Health of the City of New Orleans, 1898-1899. Paper. Pp. 138.

Clinical and Pathologic Observations on some Early Forms of Epithelioma of the Skin. By J. A. Fordyce, M.D., New York. Reprinted from N. Y. Med Jour.

Concomitant Measles, Chicken-pox and Smallpox. A Type of Enteric Fever not Typhoid. By Otto Lerch, A.M., M.D., Ph.D., New Orleans. Reprinted from New Orleans Med. Jour.

Constitution and By-laws of American Therapeutic Society. Paper. Pp. 8.

A Contribution to the Technique of Modern Uranoplasty. Sigmoid Sinus Thrombosis. By James F. McKernon, M.D., New York. Reprints.

Datos Para la Materia Medica Mexicana. Tercera Parte. Paper. Pp. 152. Mexico: Oficina Tip. De La Secretaria De Formento. 1900.

Educational and Legislative Control of Tuberculosis By Charles Denison, A.M., M.D., Denver, Colo. Reprinted from The Journal A. M. A.

Fifteenth Annual Report of the Secretary of the State Board of Health and Vital Statistics of the Commonwealth of Pennsylvania and Minutes of the Board. Presented by the Secretary, Benjamin Lee, M.D., November 23, 1899. Paper. Pp. 141. *Wm. Stanley Ray, State Printer of Pa.*

The Fracture of the Ribs. By W. A. Kuflewski, M.D., Chicago.

Heredity in Disease. By G. Archdall Reid, M.B., F.R.S., Southsea. Reprinted from the Scottish Medical and Surgical Journal.

Medicine as a Business Proposition. By G. Frank Lydston, M.D., Chicago. Paper. Pp. 32. Price $0.25. Chicago: Riverton Press.

Neurasthenia: Some Points in its Pathology and Treatment. Report of a Case of Tumor of the Cerebellum with Drainage of Fluid Through the Nose. By G. W. McCaskey, A.M., M.D., Fort Wayne, Ind. Reprints.

Ocular Complications of Variola. By Geo. F. Keiper, M.D., Lafayette, Ind. Reprinted from Med. and Surg. Monitor.

Proceedings of the Philadelphia County Medical Society. May. Paper. Pp. 240. Philadelphia. Published by the Society.

Proceedings of the Pathologic Society of Philadelphia. July. Paper. Pp. 240. Philadelphia: Published by the Society.

Pus in the Pelvis. Difficulties Encountered and Surmounted in Operations on the Female Pelvic Organs, By John L. Jelks, M.D., Memphis, Tenn. Reprinted from the Memphis Med. Monthly.

Rampancy, the Fervor of the Forehead A Study of the Anterior Metopic Lobule. By Wallace Wood, M.D. Reprinted from the N. Y. Med. Jour.

Report of the Board of Censors of the Medical Association of the State of Alabama. Submitted to, and Adopted by, the Association, During the Meeting Held in Montgomery, April 17-20, 1900. Paper. Pp. 32. Montgomery, Ala.: Brown Printing Co. 1900.

Board of Health of the State of New Jersey. Circular 100. Transportation of the Dead. Paper. Pp. 23. Trenton, N. J.: John L. Murphy Publishing Co.

A Unique Case of Double Inguinal Hernia. By W. T. Eckley, M.D., and Charles Davidson, M.D. Reprinted from Chicago Clinic.

TRADE PAMPHLETS.

Assimilation of Phosphorus. Clinical Reports on Hypoquinidol. Internal Administration of Iodin. By. R. W. Gardner, Pharmaceutical Chemist. New York.

The Wellcome Chemical Research Laboratories. By Burroughs, Wellcome & Co.

Euquinine. Tannalbin. By Merck & Co.

New Patents.

Patents of Aug. 7 to 27, of interest to physicians:

655,540. Vaginal syringe, Anton Arlt, Bad Sommerstein, Germany.

655,190. Suturating instrument, Louis Bramson, Copenhagen, Denmark.

655,601. Hernial truss, Rollo W. Browne, Washington, D. C.

655,206. Truss-pad, Austin J. Davidson, Douglas City, Cal.

655,481. Device for promoting growth of hair, Frederick W. Evans, St. Louis, Mo.

655,485. Water bag, Lorenzo M. Hansen, Moorestown, N. J.

655,490. Muscle kneader, Rudolph Hollem, Sioux City, Iowa.

655,365. Hernial truss, Henry M. Johnson, Minden, Iowa.
655657. Syringe, Frederick J. Lander, Rochester, N. Y.
655,509. Obstetrical appliance, Haldora Olson, Duluth, Minn.
655,413. Magnetic drinking cup, Herbert A. Parkyn, Chicago.
655,514. Umbilical truss, Howard C. Rash, Salina, Kan.
655,458. Making superphosphates, Heinrich Saxl, San Francisco, Cal.
655,529. Amido-sulfonic acid, Joseph Turner, Huddersfield, Eng.
655,665. Apparatus for heating and sterilizing fluids, Addison G. Waterhouse, and J. S. Forbes, Philadelphia, Pa.
655,317 Electric temperature indicator, Leslie S. Wilder, Springfield, Mass.
33,049 Design, douche pan, Daniel Hogan, New York City.
655,961. Truss, Lorenz A. Deuther, Buffalo, N. Y.
655,782. Soda water dispensing apparatus, Charles F. Kade, Sheboygan, Wis.
655,061. Producing formaldehyde vapors, Jean J. A. Trillat, Paris, France.
655,744. Syringe. Washington S. Valentine, New York City.
656,072. Soda-water apparatus, Joseph O. Wild, Holyoke, Mass.
655,747. Electromedical vacuum apparatus, George W. Winckfield, Alameda, Cal.
656,180. Machine for manufacturing nerve broaches, etc., James H. Downie, Detroit, Mich.
656,182. Sound-collector for the ears, Wm. G. Ehrhardt, New York City.
656,253. Making sodium carbonate crystals, Josef Kunstner, Obersedlitz, Aussegg, Austria-Hungary.
656,738. Combined hobby-horse and invalid's chair, Alvin J. Branham, Springfield, Mo.
656,992. Disinfectant, James L. Mortimer and J. H. Williams, Liverpool, Eng.
656,657. India-rubber water bag, John Parette, Montreal, Can.
657,003. Glycerinized vaccin lymph, Edward M. Parker, Washington, D. C.
656,862. Corn-shield, Marcus Straussberg, Newark, N. J.
656,914. Vaccin-point carrier, Ralph Walsh, Washington, D. C.
33,126. Design, atomizer casing, Isaac Q. Gurnee, Butler, N. J.
33,125. Design, inhaler, Hiram L. True, McConnellsville, Ohio.

Change of Address.

O. F. Allen, Mt. Vernon, to Mt. Olive, Ill.
M. W. Bland, Galion, to Shelby, Ohio.
A. B. Bonar, 157 W. 47th St., to 146 W. 94th St., New York City.
C. W. Baker, Blanchard, Ohio, to Stanwood, Iowa.
W. H. Boone, 197 Wood St., Chicago, to Chrisman, Ill.
Thos. H. Barlow, Alexandria, Minn., to Rush Medical College, Chicago.
H. Bergstein, Reno, Nev., to Cracker Bldg., San Francisco, Cal.
J. H. Bogle, Collinsville, to Luttrell, Ala.
T. E. Courtright, 186 W. Ninth Ave., to 859 Oak St., Columbus, Ohio.
E. L. Clawson, 18 N. McCamley St., to 232 Van Buren, W., Battle Creek, Mich.
W. C. Cundiff, Huntsville, Tenn., to Somerset, Ky.
A. Crawford, Miles, to Mt. Vernon, Iowa,
W. R. I. Dalton, 101 Convent Ave., New York City, to Delaware Water Gap, Pa.
H. G. Ebert, 412 N. 34th St., Philadelphia, Pa., to University Station, Charlottesville, Va.
Frank LeMoyne Hupp, Hulett's Landing, Lake George, to 318 W. 57th St., New York City.
S. L. Fridus, 661 W. 14th St., to 4834 S. Ashland Ave., Chicago.
W. R. Ford, Ft. Atkinson, Wis., to 6537 Perry Ave., Chicago.
B. R. Gary, 127 28th St., to 128 33rd St., Newport News, Va.
A. Graydon, Bloomsburg, to Homestead, Pa.
G. E. Garwood, Deshler to Leipsic, Ohio.
E. Gleitsman, 710 Fullerton Ave., to 1732 Diversey Boul., Chicago.
P. A. Haley, Paint Creek, to Hinton, W. Va.
F. H. Hacker, 310 Meeting St., to 113 Ashley Ave., Charleston, S. C.
W. H. Hill, Gentryville, Mo., to Peoria, Ill.
C. W. Heath, 16 Astor St., to 404 LaSalle Ave., Chicago.
E. C. Hackett, 121 W. 14th St., Dubuque, Iowa, to 298 Maxwell St., Chicago.
C. E. Ide, Newport, N. H., to 192 E. Superior St., Chicago.
S. H. Kempner, Milford, Conn., to 168 W. 130th St., New York City.
George M. Lucas, Malta, to 265 Milwaukee St., Elgin, Ill.
W. C. Leary, Fitten Bldg., to Austell Bldg., Atlanta, Ga.
A. O. Loe, Crookston, Minn., to York Bldg., Seattle, Wash.
H. G. Mertins, Ashland, to Washburn, Wis.
W W. Miller, 84 Worcester St., Boston, Mass., to 52 E. Range St., University of Virginia, Charlottesville, Va.
L. F. Michael, Dulce, N. M., to Ponca City, O. T.
H. C. Miller, Gibbs Blk., Findlay, Ohio, to Cambria, Mich.
John L. Morse, 317 Marlborough St., to 70 Bay State Road, Boston, Mass.
Geo. W. May, Haverhill to Cascade, Iowa.
W. O. Nisbet, Waxhaw, to Charlotte, N. C.
L. J. Perkins, Pendleton Ore., to 2909 University Ave., Des Moines, Iowa.
F. Purdue, Alto Pass, to Lyndon, Ill.
M. Ravn, Scandinavia, to Merrill, Wis.
J. B. Sweeney, Manistique, Mich., to Green Bay, Wis.
J. Sjoquist, Chicago, to Holdrege, Neb.
F. D. Stricker, 337 E. Congress St., to 616 Elmwood Ave., Detroit, Mich.
M. Scanlan, Lost Nation, to DeWitt, Iowa.
E. R. Scholten, 4603 State St., to 4412 Wabash Ave., Chicago.
W. A. Starner, 169 Ponce de Leon Ave., to 24 Kelly St., Atlanta, Ga.
C. A. Smith, 1003 Spruce St., Philadelphia, Pa., to English-American Bldg., Atlanta, Ga.
T. E. Taylor, Steele Blk., to Denison Blk., Denver, Col.
R. H. Wright, Petersburg, Va., to Haskins Hospital, Wheeling, W. Va.
J. W. Worrell, Brownsville, to 128 S. Negley Ave., Pittsburg, Pa.
C. E. Wehrle, 1006 Washington St., to 2109 Robinwood Ave., Toledo, Ohio.
G. H. Willis, 6917 Eggleston Ave., Chicago, to Galien, Mich.
F. J. Will, Eagle Grove, to Equitable Bldg., Des Moines, Iowa.
W. B. Wells, Milton, Wis., to 108 Honore St., Chicago.
C. E. Weber, 5554 Ellis Ave., to 4304 Grand Boul., Chicago.
W. H. Walker, Utica, Neb., to 750 Harrison St., Chicago.
J. G. Wilkins, Fitten Bldg., to Groat Bldg., Atlanta, Ga.
J. E. Wheat, Los Angeles, to Fernando, Cal.
W. N. Wade, Lompoc, to 1516 Castillo St., Santa Barbara, Cal.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., August 22 to 28, 1900, inclusive:

James K. Ashburn, acting asst.-surgeon, from Batavia, Ohio, to San Francisco, Cal., to accompany troops to the Philippines.

Louis Brechemin, major and surgeon, U. S. Army, sick leave extended.

Joseph J. Curry, acting asst.-surgeon, leave of absence granted on account of sickness.

Calvin DeWitt, lieutenant-colonel, deputy surgeon-general, on expiry of present leave to report at St. Paul, Minn., for duty as chief surgeon, department of Dakota, to relieve Colonel Joseph P. Wright, assistant surgeon-general, U. S. Army.

P. C. Field, acting asst.-surgeon, leave of absence extended.

Aubrey F. Higgins, acting asst.-surgeon, former orders revoked; he will proceed to Philadelphia, Pa., for annulment of contract.

David J. Johnson, acting asst.-surgeon, former orders amended to read from Plattsburg Barracks to Fort Ontario, N. Y.

William L. Little, acting asst.-surgeon, from Fort Clark to San Antonio, Tex., for duty with troops of the 25th Infantry under orders for the Philippines.

Robert J. Marsh, acting asst.-surgeon, from the department of Alaska to Portland, Ore., for annulment of contract.

William O. Owen, major and surgeon, U. S. Army, to represent the medical department of the army at the meeting of the American Health Association at Indianapolis, Ind., October 1 to 5, 1900.

Benjamin F. Pope, lieutenant-colonel, deputy surgeon-general, U. S. Army, from temporary duty at the Presidio of San Francisco, Cal., to permanent station at that post.

William E. Purviance, captain and asst.-surgeon, U. S. Army, from Fort Egbert, Alaska, to duty in the Department of California.

Charles Richard, major and surgeon, U. S. Army to represent the medical department of the army at the meeting of the American Public Health Association at Indianapolis, Ind., October 1 to 5, 1900.

William E. Richards, lieutenant and asst.-surgeon U. S. Army; previous orders amended to read from Fort Ontario to Plattsburg Barracks, N. Y.

Charles F. Sanborn, acting asst.-surgeon, previous orders directing him to proceed to San Francisco, Cal., to accompany troops on foreign service revoked.

Herbert F. Saunders, acting asst.-surgeon, from Greenville, Ala., to San Francisco, Cal., to accompany troops going on foreign service.

Herman J. Schlageter, acting asst.-surgeon, from the Department of Alaska to Vancouver Barracks, Wash., for temporary duty.

Howard W. Seager, acting asst.-surgeon, from Des Moines, Iowa, to San Francisco, Cal., to accompany troops going on foreign service.

Henry A. Shaw, captain and asst.-surgeon, U. S. Army, former orders amended so as to direct him to report at San Francisco, Cal., for transportation to Manila, for duty in the Division of the Philippines.

William D. Shelby, acting asst.-surgeon, on expiry of present leave to proceed from Fort Thomas, Ky., to San Francisco, Cal., for duty with troops going on foreign service.

Alva D. Williams, acting asst.-surgeon, from Jacksonville, Fla., to San Juan, Porto Rico, for duty in that Department.

William B. Winn, major and surgeon, U. S. Vols., former orders amended so as to direct him to report at SanFrancisco, Cal., for transportation to Manila for assignment to the Division of the Philippines.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Sept. 1, 1900:

Medical Inspector P. M. Rixey, commissioned medical inspector from Aug. 24, 1900.

Surgeon G. T. Smith, commissioned surgeon from Aug. 24, 1900.

P. A. Surgeon A. M. D. McCormick, detached from the *Chicago* and ordered to the *Montgomery*.

Asst.-Surgeon J. R. Whiting, detached from the *Montgomery* and ordered to the *Chicago*.

P. A. Surgeon M. R. Pigott, ordered to the Naval Academy immediately.

Asst.-Surgeon C. A. Crawford, detached from the *Chesapeake* and ordered to the *Eagle*.

P. A. Surgeon L. W. Spratling, detached from the naval hospital, Yokohama, Japan, upon reporting of relief, and ordered to report to the commander-in-chief of the Asiatic Station for such duty as may be assigned.

Asst.-Surgeon F. L. Benton, detached from the naval hospital, Cavite, P. I., and ordered to the naval hospital, Yokohama, Japan, for duty.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending Aug. 30, 1900:

Surgeon P. M. Carrington, granted leave of absence for one month from Sept. 4.

Surgeon L. L. Williams, to assume charge of Purveying Depot for two days.

Surgeon G. T. Vaughan, granted leave of absence for fifteen days from Sept. 1.

P. Asst.-Surgeon W. G. Stimpson, granted leave of absence for fifteen days from Aug. 28.

P. Asst.-Surgeon J. M. Eager, granted leave of absence for four months from Nov. 30—permission to go beyond sea.

P. Asst.-Surgeon A. R. Thomas, to proceed to Glasgow, Scotland, for temporary duty.

Asst.-Surgeon G. M. Corput, granted leave of absence for seven days.

Asst.-Surgeon F. J. Thornbury, granted three days' extension of leave of absence.

Acting Asst.-Surgeon J. P. C. Foster, granted leave of absence for sixteen days from Aug. 28.

Acting Asst.-Surgeon J. W. Stevenson, granted leave of absence for twenty-one days from Sept. 3.

Hospital Steward, George A. Morris, to proceed to New York (Stapleton), and report to medical officer for duty and assignment to quarters.

APPOINTMENT.

Mark H. Watters, of Vermont, appointed junior hospital steward.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended Aug. 31, 1900:

SMALLPOX—UNITED STATES.

Alaska: Cape Nome, from beginning of outbreak to Aug. 23, 23 cases.

Colorado: Denver, Aug. 11-15, 3 cases; Garfield county, Aug. 4, 1 case; Las Animas County, Aug. 7, 1 case.

Louisiana: New Orleans, Aug. 18-25, 9 cases, 2 deaths.

New York: New York, Aug. 18-25, 1 death.

Ohio: Cleveland, Aug. 18-25, 4 cases; Dayton, Aug. 18-25, 1 case; Portsmouth, Aug. 18-25, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, July 28-Aug. 1, 8 cases.

Belgium: Antwerp, July 28-Aug. 4, 2 cases.

Egypt: Cairo, July 22-29, 1 case.

England: London, Aug. 4-11, 5 cases.

France: Lyons, July 28-Aug. 4, 2 deaths.

Germany: Berlin, Aug. 10, 3 cases.

Gibraltar: Aug. 5-12, 2 cases.

India: Bombay, July 24-31, 2 cases.

Russia: Moscow, July 28-Aug. 4, 2 cases, 2 deaths; Odessa, July 28-Aug. 11, 108 cases, 29 deaths; Warsaw, July 28-Aug. 4, 7 deaths.

YELLOW FEVER.

Colombia: Barranquilla, Aug. 5-12, 1 death; Panama, Aug. 13-20, 4 cases.

Costa Rica: Port Limon, Aug. 22, 1 case on S. S. *Cunard*, from Colon.

Cuba: Havana, Aug. 4-11, 18 deaths; Matanzas, Aug. 26, 1 case.

France: Havre, Aug. 11, 1 case on S. S. *Caravallas*, from Lorenzo Marques, via Senegal; Aug. 13, several cases on S. S. *Santa Fe* from Lorenzo Marques, via Senegal.

Mexico: Merida, July 3, 7 cases, 4 deaths; Tampico, Aug. 16, 1 death.

CHOLERA.

India: Bombay, July 22-31, 379 deaths; Madras, July 21-27, 5 deaths.

PLAGUE.

Australia: Sydney, to July 28, 302 cases, 102 deaths.

India: Bombay, July 24-31, 45 deaths.

Scotland: Aug. 31, 11 cases.

Turkey: Smyrna, from outbreak to Aug. 6, 22 cases, 11 deaths.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. *Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and* should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be *considered the exclusive property of the Association*. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, *unless specially instructed to the contrary by vote of the Association*." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal *when photographs or drawings are supplied by the author*.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, *in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs.* Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the
American Medical Association

VOL. XXXV CHICAGO, ILLINOIS, SEPTEMBER 22, 1900. No. 12

Address.

SPECIALISM IN MEDICINE.*

FREDERICK C. SHATTUCK, M.D.
Jackson Professor of Clinical Medicine, Harvard University, etc.
BOSTON.

When, under the influence of faulty metabolism or other cause, pessimism gets the better of us, we sometimes quote with approval the remark of Solomon the Wise, that there is nothing new under the sun, without reflecting that Solomon himself was probably not feeling his best at the moment. Something in his internal or large domestic economy had gone wrong, I suspect. Possibly he had to write an address! However, this may be, let us suppose him suddenly brought for a visit to one of our large cities. He would certainly find that advance in knowledge has brought about great change in our relation to things, be the things themselves never so ancient or immutable. Solomon was at the *fin* of his *siècle*, but the old sun looks down on a different world at the *fin* of this *siècle*. He could not fail to be impressed by the subdivision of labor of the present day in every branch of industry. Were the great king to be seized with sudden abdominal pain he would surely have the benefit of a surgical and a medical opinion. Another doctor would make a blood count, another a urinary examination, another, perhaps, would examine his vomitus or stools; another, use the X-ray. If his abdomen were opened the pathologist would report on cultures from the cavity, or on the structure and nature of any suspicious tissue. It would, in a word, be demonstrated to him that specialization has taken place in the science and art of medicine, as in other sciences and arts. And Specialism in Medicine is the theme which I have selected for brief and, I fear, inadequate consideration during the time your president has done me the great honor of delivering you into my hands.

A line of cleavage appeared first perhaps between medicine and surgery; and it is curious to note that nowhere has the line, at least in name, in the past been so closely drawn as in England, where more minute specialization has met with considerable opposition. Toward this result the anomalous fact that the degree of Doctor of Medicine has in England been only a University title, must, it seems to me, have contributed. Practically everywhere else in the civilized world the practitioner is a Doctor of Medicine. Although we have a fair working knowledge of the distinction between medicine and surgery, I, at least, find myself unable to frame a satisfactory definition of the distinction. Some thirty years ago, during my medical studies, I had the pleasure of meeting the late Mr. Holden, then of Bartholomew's Hospital, and was asked by him whether I meant to be a physician or a surgeon. On my reply that I looked forward to being a physician, he remarked, "Don't you do it; the surgeon can do all the physician can, and more too." When I repeated this remark to dear old Sir Henry, then Doctor, Acland, he dryly remarked that he should be very grateful to Mr. Holden if he would come and teach him how to do some of his work. Much more recently I have heard of a very distinguished London surgeon defining a surgical case as one which paid him two guineas. Anesthesia greatly enlarged the bounds of surgery, and yet twenty-five years ago there was not a pure surgeon in America. The surgeon did as much general practice as he could get, including midwifery. Surgical cleanliness has worked a great change in this respect, and the end is not yet in sight. We see men to-day, even in relatively small communities, confining themselves strictly to surgery. Without much exaggeration one can say that it is as hard to-day to live on medicine alone as it was twenty-five years ago to live on surgery alone. "Belly-ache" is now a surgical disease. I know of a child with pneumonic pain referred to the right iliac region being operated upon for appendicitis. A few years ago a woman was sent into the surgical wards of the Massachusetts General Hospital for operation, perhaps for extrauterine pregnancy. The surgeon, who had had a large general experience, noticed wrist-drop and a blue line on the gums, and transferred her without operation to my wards. So safe now-a-days is the use of the knife under proper precautions that there is temptation to use it for purely diagnostic purposes. Just when to yield to and when to resist this temptation requires good judgment and general knowledge. The heart is practically the only viscus which remains the exclusive province of the physician. That organ is more tolerant of insult than has been supposed, and who shall dare to say that, impossible as it seems now to us, a contracted mitral valve can not be slit without causing death? The real line between medicine and surgery is one thing; the practical line is another. The last quarter century has seen them approximate notably, but they will not coincide until knowledge is perfect. The establishment of a German journal devoted to the borderlands of medicine and surgery is interesting.

Obstetrics, again, early became a specialty; though in rather a different way. For parturition is a physiologic process, and in many countries a large proportion of births are now under the sole charge of midwives. In this country the general practitioner has clung to his obstetrics as a necessity for family practice, oftentimes bewailing his hard fate and interrupted nights, meanwhile. Of late years we see in the larger centers a ten
ency of obstetrics, at least among the go
the hands of a few men, who, on the of
puerperium, withdraw, the family su
his place. This is a practice which
can obtain only in large communi

---

* The Address in Medicine, delivered before the Canadian Medical Association, Ottawa, Ont., September 13.

propriateness we see these obstetricians also busied in diseases peculiar to women, many of which are the outgrowth of one or more previous pregnancies.

Gynecology is of almost unique interest from the point of view of Specialism in Medicine, and a medical Gibbon could write an interesting book on its Rise and Fall. Not many years ago it was, I am tempted to say, the most in evidence of any specialty into which enterprising young men were ambitious of crowding themselves before the ink on their diplomas was scarce dry. The mills of the gods grind no less fine than they did, but, I think that they grind quicker in these electric days. Pure gynecology to-day scarcely exists. Many deviations from the normal in the female pelvis give rise to no symptoms until the general health begins to fail, from one cause or another. Such cases belong to and are best treated, ordinarily, by the wise general practitioner. If I read the signs of the times aright, what may be called pelvic tinkering, which has been so much practiced in the last decades, is suffering from a rapid decline. What is really necessary can safely and best be left in the hands of the obstetrician alone or aided by the general physician; and major gynecology, the great bulk of which involves laparotomy, seems to be going where it belongs—into the hands of the general surgeon. It may all have been a necessary sequence in the evolution of knowledge, or I may be ignorant or prejudiced, but I can not look at the groping course of gynecology as a triumph of human intelligence.

How many women have been unnecessarily deprived of necessary sexual organs; how many have had their attention fixed on these organs, which in the male nature has left in evidence, but in the female has modestly hidden away, affording, like all hidden or veiled things, wide play to an awakened imagination!

On the eve of reading this I see the following words just from the pen of Prof. Howard Kelly, of the Johns Hopkins, certainly a competent witness: ". . . the general adoption of the principles of asepsis leaves the barrier between general surgery and gynecology a purely artificial one, and one which must inevitably, sooner or later, be broken down. My advice, therefore, to all gynecologists is to study general surgery and become general surgeons first."[1]

Surgery and obstetrics seem likely always to hold their places as great divisions of medicine as a whole. Let me now turn to the subdivisions of medicine, as contrasted with surgery and obstetrics, and try to consider specialization in connection with its etiology. The first place among the causes for the increase in specialism doubtless belongs to increase in knowledge. A half century ago James Jackson, than whom my native city has produced no wiser physician, said that there was more actually known in medicine than the mind of any one man could grasp. If this was true fifty years ago, how much more true is it of the present day. The field is so large that no one man can possibly oversee and bring it to full productiveness. Each crop needs a separate head of the first class. But here, perhaps, as well as elsewhere, I may state that I trust nothing I say can be construed into any slight on the general practitioner, especially on the men who in small communities are liable to be called upon to deal with any emergency of any kind pertaining to medicine in its broadest sense.

All honor to those to whom honor is due. Those of us who dwell in large cities and have the advantage of the presence of experts in every line at instant call are, I believe, keenly alive to the danger of one-sided development to which we are exposed, and to the lack of self-reliance and resource following from this, when we get off our narrower or wider beaten track. I simply mean that the highest excellence, knowledge and skill in all branches of medicine are simply impossible of attainment by any one man—a proposition which must command universal assent.

The specialty of neurology seems to me a case in point. Great advances have been made in our knowledge of the anatomy and physiology of the nervous system in recent years, though there is still enough which is obscure. Neurology deals with a system rather than with an organ; has length and breadth, touches medicine at very many points, and thus involves less risk of narrowness of view to its devotees than do some specialties. A general practitioner once shrewdly remarked to me, "It takes a mighty big man to be a specialist." The neurologist must also have large knowledge of the diagnostic and therapeutic uses of electricity.

Diseases of the skin, with its appendages, accessible as they are directly to sight and touch, form one of the earliest of modern specialties. As coming under external pathology they were formerly considered rather the province of the surgeon than of the physician. The dermatologists have simply justified their existence, and have profited to the full by the impetus which bacteriology has given to all branches of medicine.

It is only in centers of population that the specialist can get a support. In the increase of these centers lies the second factor in the etiology of specialism. Not only are cities growing in numbers and size, but the means of rapid and ready travel are so multiplying that the hope of relief from mere inconveniences, perhaps, makes people everywhere intolerant of ills which, in earlier times, they resigned themselves to bear as best they could. I have often thought what a wonderful field London offers for the development of the highest and best specialism. Quite apart from her five million inhabitants, she is within relatively short reach of any part of the United Kingdom. Besides this, people bring back from the English colonies scattered over the world many kinds of strange ailments and all manner of climatic results. There one may lay his foundation broad and deep, can keep in touch with the larger aspects of medicine, and can be gradually converted into a specialist, even of an organ, if he wish. His consulting-room is a filter for thirty odd millions of people. He can legitimately be forced into a specialty—quite a different thing from forcing himself into one. Other things being equal, the larger and wider his general experience has been, the better specialist and the bigger man will he be.

A third factor in the increase of specialism grows out of our first. Inventive talent is leading more and more to the possibility of direct examination of organs and cavities which were formerly closed to our eyes and touch. The proper use of many of these aids requires a long apprenticeship. The limits of physiologic variation must be learned, and delicacy and skill must be acquired in the use of instruments more potent for harm than good in untrained hands. Manual dexterity, impossible to some, and attainable by any only with practice, is added to general knowledge and good judgment. Ophthalmology, demanding also a wide knowledge of optics, affords a good illustration. The otologist should know much of acoustics. The nose and throat are so intimately connected with the ear, and form the starting-point of so many ear diseases, that it seems to me they should all be included in one specialty rather than in two, as is generally the case at present. The addition of the larynx would seem to unduly enlarge the field.

---

[1] Philadelphia Medical Journal, Sept. 1, 1900, p. 391.

I can not see that there is now, at any rate, enough special knowledge and technical skill involved in the diagnosis and treatment of digestive disorders to warrant their separation into a true specialty. Yet a National Association of Gastro-Enterologists has, I believe, been formed in the United States. Time is inexorable and will settle the real status of the matter, so I will refrain from prophecy, bearing in mind the adage, "Don't never prophesy unless you know."

So much training is required to attain the best results with the X-rays that their use seems likely to fall largely into the hands of specialists, particularly where neither bones nor foreign bodies are in question. Y and Z rays may also be discovered, and broaden the specialty.

The three factors in the multiplication of specialties already mentioned—increase of knowledge, aggregation of population with rapid and frequent means of transit, and the invention of instruments requiring delicacy of use—may be regarded as inherent.

Besides these there are another three which I should class rather as accidental. A man may, first, have a special aptitude or taste, leading him to limit his work. This may be dangerous to indulge, or, at least, to indulge too early. The director of a modern gymnasium searches out the weak points in a would-be athlete, and, by attention to them, encourages symmetrical development. Next is a desire on the part of some to escape the hurly-burly of general practice, its irregular hours, and what they deem its slavery. This desire may be based on delicate health or indolence. The latter is no more likely to render good service to the community in a specialty than in general work. Thirdly, the hope of greater emolument with less toil may be added. People will pay larger fees for what they consider special knowledge, and the number of persons who can afford indulgences of all kinds is large and rapidly increasing. The ophthalmologist gets more for removing a speck of dust from the eye than does the general practitioner.

Specialism divides up the organs and systems of the body, separates the sexes in a measure, and still insatiate, steps in between children and parents. Shall we see parents and grandparents similarly set apart? Why not a chair in medical schools for the diseases of old age, as well as for the diseases of children? It is a conservative statement that the pathology of old age is at least as peculiar as is that of childhood. Infant-feeding alone affords scant material for a specialty, particularly if the profession as a whole would insist more on the use of nature's provision for young mammals, apparently sufficient for all of this class, save man. The number of women who can nurse their children is much larger than is that of those who do.

There are no instruments of precision or diagnostic procedures used in the diseases of children which are not in common use in adults—at least as far as I know. Of course, pathology is modified by age; but the differences seem to me minor. It is pleasanter to float on a flood than to struggle against an ebb tide. This may partly account for the apparent lack of enthusiasm for association exclusively with the diseases of the aged.

All the specialties which have been thus far mentioned are followed by men coming into continual contact with sick people, by men in active practice, so-called. The day is passing in America, and has indeed passed in the larger centers, when teachers of anatomy, physiology, and pathology can also be practitioners of medicine. These fundamental branches have become specialties, as far as teaching and research go, and an increase in the number of their followers can confidently be expected. Bacteriology is, in a broad sense, merely a department of biology. But the methods of study involved in the minute size and other attributes of the forms of life with which bacteriology deals, and the vast amount we have still to learn with regard to these organisms, affords full occupation for a large band of special workers.

Biologic chemistry, again, promises a large and productive field for a considerable number of special workers. Hygiene and experimental pharmacology also should be mentioned. The lines of cleavage between these more purely scientific specialties, just as between the practical specialties, are apparent rather than real—a matter of convenience rather than principle. Increase of knowledge will bring rearrangement of some of these specialties at the same time that it may tend to increase their number.

We practitioners can not be too grateful to the men who are willing to eat the bread of carefulness and devote their energies to the study and teaching of principles. We deal mainly with individual cases of disease. We try to cure or palliate the manifestations of disease in single cases as they come to us. Their aim is to make it possible, through determination of the causes of disease, to, in the first place, prevent them, and, in the second place, enable us to treat the disease itself when it does arise, rather than merely to treat the patient, as we still so often have to do.

Malaria and syphilis stand practically alone as diseases for which specifics have been stumbled on in the course of ages. Our recent gain in knowledge as to the causation and mode of transmission of malaria has not, as yet at least, added materially to our control of its symptoms or origin. And we are still in dense ignorance as to the real cause of syphilis. But within a few years myxedema, diphtheria, and I think it is safe to add hydrophobia, have been added to the list of diseases which we treat directly, and we seem to be on the eve of important further additions to this list.

Formerly shrewdness, "horse sense," and knowledge of human nature were more important elements in successful practice than even medical knowledge. Hence our ignorance has compelled us to treat the patient rather than the disease. And herein lies a great strength of quackery. Suggestion may be a more potent therapeutic agent in the hands of an unscrupulous and positive man, ignorant though he be, than in the hands of a highly-trained and conscientious man, handicapped often by a painful realization of his ignorance. Just in proportion to the advance in exact knowledge are the main props of quackery weakened. It is to special workers in special fields that we must look for this advance.

One is half tempted sometimes to think that the medicine of the future will be robbed of a charm which inheres in it to-day—the charm, namely, which belongs to the element of uncertainty, and the stimulation which this should bring to thought. The impulse is strong to cut the Gordian knot of abdominal diagnosis as has been already mentioned. Fine methods of research will gradually substitute certainty for uncertainty. But diagnosis is not likely ever to become a mere penny-in-the-slot affair, and the management of the patient—the art of medicine—will ever remain important, though more and more subordinate in the drama of medicine and human suffering.

Specialization is evident in hospi[illegible] vate practice. The ideal hospital poor can have the benefit of the highest skill and attainment in every branch of medicine—a beneficent trust in which specialists are associated and harmoniously work together. It must also be a center of medical teaching and research, opportunities for which constitute the return from the inmates for the benefits received. It seems to me a question how far it is wise to encourage the establishment of special hospitals devoted exclusively to this or that age, sex, or class of disease. The isolation of the staff of a special hospital has its manifest disadvantages. The creation and support of the more minute special departments in a general hospital dependent for its maintenance on the public spirit of private persons has its patent practical inconveniences and difficulties. The general hospital must follow, not lead, in specialization, and can not afford the luxury of "fads" unless it is far richer than are the general hospitals of which I have knowledge. Although hospitals are not business enterprises, one of their sinews is money, another, the devotion and capacity of the medical staff. The same administration can, given the funds, run a general hospital formed of a congeries of special departments as well as, and at less cost than, separate administrations can run a number of special hospitals.

It is all very well to say, "Take no thought for the morrow"; if our predecessors had acted literally on this precept we should be in a bad way. Progress will march and evolution go on in spite of us, doubtless. But we can have some influence over the rapidity of evolution, and it is our business to do what we can to foster right and to discourage wrong tendencies. One fact stands out clearly—that specialism in medicine has come to stay. Its advantages infinitely outweigh its disadvantages, and we have faith that all things work for good in the long run.

We study the past, and speculate as to the future. We all sometimes feel as did the late Dr. Hagen, the great entomologist—"I should like to be my own great-grandson." We can not greatly influence the amount of pity which our great-grandsons may feel for our attainment, but we can force their respect for our honest and unremitting effort.

TRAUMA AS A CAUSE OF NERVOUS DISEASES.*

CHARLES W. BURR, M.D.
NEUROLOGIST TO THE PHILADELPHIA HOSPITAL.
PHILADELPHIA.

The subject assigned to me is so large that it is imposible to give it exhaustive study in the time at our disposal. I shall speak briefly about a number of different affections, shall quote no authorities, and shall try to confine myself to matters which will lend interest to the discussion. I shall speak solely of the causative influence of trauma and of the various ways in which it acts, and shall say little or nothing concerning symptomatology. Finally, I shall omit all consideration of the diseases which result from manifest physical injury to the bony coverings of the brain and cord, such as fractures and dislocations, and shall say nothing of such well-known conditions as cerebral concussion, meningeal hemorrhage and traumatic epilepsy, and shall consider only the organic and functional diseases unaccompanied by serious external injury.

To prove the traumatic origin of a disease may be easy or difficult. It is not safe to say always that because a disease follows a trauma, therefore it is the result even though the association of the two be very frequent. It must be shown that in the nature of things the trauma is competent to produce the disease; it must be shown how it acts—by what mechanism—and, best proof of all, there must, in organic diseases, be the post-mortem evidence of an injury having been sustained. Popularly many of the acute and almost all of the chronic diseases of the spinal cord and brain are supposed to be caused by injury. Almost every patient refers his illness to some accident which occurred in the more or less remote past. It is an easy explanation and is sometimes accepted without much thought or investigation. In the text-books trauma is put down along with exposure and cold, as one of the subsidiary causes of many things. In recent years, however, the entire question has been carefully and systematically studied and though much remains in dispute some progress has been made and a few problems definitely settled. That trauma may without injury to the skull or spine produce organic disease referable to the brain or cord is now accepted by everyone competent to have an opinion. Further, certain functional nervous diseases may result from accident, and indeed from shock or fright alone without any physical injury. Finally, organic and functional symptoms are frequently associated. Whether any of the system diseases of the spinal cord are ever caused by accident alone is still in dispute. It has been frequently alleged, for example, that locomotor ataxia may result from injury. The only evidence on which this opinion is based is the more or less complete proof of the absence of syphilis and the history of an injury to the back at the time when the patient thought himself to be in good health. In truth, the determination of the causation is difficult. Syphilis precedes it more frequently than any other disease, being present in at least 80 per cent. of all cases. On the other hand, the morbid anatomy of locomotor ataxia bears no resemblance to that of spinal syphilis, and mercury and iodid of potash are of no worth in its treatment. We are forced, then, if we accept syphilis as the one great primary cause—as indeed we must—to regard it either as an indirect cause simply, as a poison which so acts on the peripheral sensory neurons as to make them more sensitive to the influence of some other direct cause, or else to assume that syphilis generates some secondary poison which in turn causes the lesions. To explain the 20 per cent. of cases in which syphilis can be excluded is difficult. To prove that trauma is a cause is not easy. Locomotor ataxia is a disease of indeterminate onset and insidious course. You can not say of any case, on such a day this man was well, on the next day ill. The patient's statement as to the time of onset is valueless, for the disease may exist for some time without causing any symptoms recognizable as such by him. It is, therefore, frequently impossible to know if, at the time of the injury, the patient was free from disease. I do not know of any case in which it has been proved by medical examination a short time before the accident that the patient was normal in all regards.

Again, what time-limits are we to set upon the active influence of a trauma? How soon or how late may symptoms caused by it first appear? May there be a quiescent interval of months or years, or must there be a continuous sequence of symptoms from the time of receiving the injury in order for it to be regarded properly as their cause? The answers will depend largely upon the personal equation of the observer and his mental bias. If in one case soon or immediately after an injury happening to a man in known good health there should develop the classical symptoms of locomotor ataxia, it would be proper to carefully consider whether the injury might not have been the cause. If such cases were frequent and if it were proved that injury could produce such widespread lesions as are present in this disease, then it might be accepted as a cause. But locomotor ataxia is very common, and cases with a clear history of trauma are very rare. I am compelled to believe that the causative influence of trauma is as yet unproved and must agree with Dr. Morton Prince in saying, "when a sclerosis of the posterior columns develops after a traumatism, the subject was already doomed to this condition, the process having already begun, and that the traumatism at most only accelerated the development of the symptoms and possibly of the anatomical process." The symptom ataxia may, of course, occur in many affections of the spinal cord, resulting from trauma. The arguments used concerning locomotor ataxia apply with equal force to general paralysis of the insane, except that a history of traumatism, especially to the head, is much more frequent in the latter disease. But granting this, it has not been proved that traumatism alone, acting on a man in good health, who has not had syphilis, who is not an alcoholic, whose heredity is good, and who has not been subjected to severe mental or emotional stress, can cause general paralysis. That it may be a minor causative factor, as it were the match to the powder, is surely true. Other types of mental disease, other forms of organic dementia, not infrequently result from more or less serious injury to the head, and certain insanities may occur without any external hurt at all.

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The influence of trauma in causing tumors of the nervous system is only a part of the larger question in pathology, namely, the relation of trauma to new growths in general. Injury may, under certain circumstances and as concerns certain tumors, determine the seat of appearance. Injury to the head, with or without fracture, may be the direct and positive cause of a fibroma and the exciting cause of other tumors. Beyond this, for our purpose, the question is of little practical importance, for no one would base the diagnosis of tumor on the mere fact of a previous injury. Given a case of brain tumor without focal symptoms, evidence of an injury, no matter of how long standing, would be of some localizing value, but would throw no light on the nature of the growth.

The question attracting most attention to-day is how far and in what manner accidents cause certain groups of spinal and cerebral symptoms when there has been no gross visible or palpable injury to the skull or spine, or indeed no physical injury, but only fright. Erichsen was the first to study this question. He found that after accidents, especially those in which there was a large element of the horrible, there occurred in the patients groups of symptoms of certain types. Though he recognized the hysteric nature of some of them, he gathered the larger number into one class and believed them to be caused by spinal concussion. His book received considerable adverse criticism. The genuineness of the symptoms was denied and occasionally his own integrity was impeached. But time passed and it was proved that his histories were true; that such symptoms as he described do occur and are not necessarily fraudulent; that they are not the invention of evil-minded neurologists; that to carefully examine a patient, even going so far as to test his knee-jerks, will not necessarily scare him into a serious fit of illness; that the bulldozing method of treating hysteria fails, and that because a man gets well after a *financial settlement does not prove* he was never ill. It has also been proved that some of the symptoms which he explained by spinal concussion are produced in other ways. Recently, there has been a tendency to deny the possibility of spinal concussion on the ground that the cord is so well protected by its bony, ligamentous, and muscular coverings, so well supported by its nerves, and so surrounded by the spinal fluid that for mechanical reasons concussion can not occur. This is probably a little too radical. The evidence in favor of concussion from experimentation on lower animals is not of great value, for the results of different observers do not agree, and the anatomical or rather the mechanical differences between man and the smaller animals are so great that its existence in the latter would not prove its occurrence in the former.

On the other hand, to claim that all symptoms may be explained by gross lesions, hysteria or neurasthenia, begs the question. The matter has been somewhat clouded by a lack of exactness in defining spinal concussion. It probably would be best to define it as that condition in which after physical force has acted on the back itself, or on some part of the body which can transmit the force to the spine, there occurs a series of symptoms referable to the cord and produced without any visible injury to it, or to its membranes, or to the vertebræ, though later there may appear lesions of the cord not caused by hemorrhages, however small, but by a degeneration of the nervous elements themselves and beginning in them. There are both clinical and pathologic reasons for the belief in the existence of such an affection. Cases occur in which recovery is so rapid, the symptoms are so transient, that organic disease can not have been present. Acute cases showing exclusively spinal-cord symptoms, have been examined post-mortem with entirely negative results. In other cases, lesions have been found which have been believed by competent observers to have primarily affected the nervous elements themselves, and not to have been secondary to muscular or other gross injury.

There is no sharp line dividing spinal concussion as here defined, from myelitis caused by multiple hemorrhages. The symptoms of the two conditions merge. At one end of the series we find a group of transitory symptoms surely caused by disturbance of the functions of the cord without organic lesion discoverable by any means at our command, at the other the complete picture of serious organic disease.

One of the most interesting and, recently, most studied traumatic affections of the spinal cord, is fairly massive hemorrhage followed often by the formation of cavities. It is most frequent in cases of fracture and dislocation, but may occur without external injury. It seems to be usually located in the cervical region, probably because of the great mobility of the neck and the poor protection of the cord in that region. The gray matter is its favorite seat, but it sometimes occurs in the white matter, and occasionally extends into a dilated central canal. The symptoms depend, of course, on the seat and extent of the hemorrhage, the character of the cavity, and the amount of myelitis, but as a rule they are characteristic. Focal spinal-cord symptoms, sudden in onset, mean hemorrhage. Symptoms of a [illegible] *te* transverse lesion, which rapidly recede and leave only those pointing toward destruction of a small area, also mean hemorrhage. Hemorrhage often causes a Brown-Séquard palsy, sometimes simulates syringomyelia, but does not apparently ever give the complete symptomatology of that disease.

Traumatic lumbago is always placed among the nervous diseases, though in a strictly scientific classification it should be put among the diseases of muscles. It is caused always by direct injury—a blow on the back, sudden forcible bending, or a crush. Since it practically never ends in death, our knowledge of its morbid anatomy is scant. The best explanation of it is a tearing of some of the bundles of muscle-fibers, with extravasation of blood, and strain of the muscular and spinal ligaments. Sometimes there is also a real traumatic neuritis.

In recent years much attention has been given to the functional diseases resulting from trauma. The first question in my case, assuming the illness to be genuine, is whether the symptoms are caused by organic disease, or are what we must still call functional, or a combination of the two. Sometimes the answer is plain, sometimes the most skilful observer will hesitate to give a positive opinion. The grounds on which the diagnosis of functional or organic disease is based have shifted greatly. For a time, single symptoms were depended upon, and not many years ago, some surgeons claimed that the absence of muscular wasting excluded organic disease. No one makes this claim to-day, but others as groundless are sometimes heard. All the symptoms must be considered in forming an opinion.

The two great functional nervous diseases, that is, the two great diseases of unknown morbid anatomy, are hysteria and neurasthenia. Both frequently follow an accident, are much more frequent in adults than in children, and are sometimes quickly recovered from after a legal settlement is made. Both are sometimes pretended fraudulently to exist. That they may be caused by trauma is admitted by all competent to have an opinion. Concerning the manner of causation we have much to learn. It is certain that there is no lesion in hysteria discoverable by our present means. It occurs practically only after accident in which there is an element of fright, and sometimes, indeed not infrequently, there is no physical injury at all. It is curious that serious physical injury is rarely followed by hysteria, and it occurs very rarely after grave surgical operations. This is not explained by saying that severe injury insures against hysteria. The probable explanation is that there must be time enough for the patient to perceive the horror of the accident while fully conscious. Drunken men and little children almost never get traumatic hysteria, and patients go to operation reassured that no evil will result. A strong effort has been made to group together certain symptoms, some hysterical, some neurasthenic, under the title of the traumatic neurosis. It is doubtful if this serves any good purpose. Hysteria and neurasthenia, following accident, differ in no way from the same diseases when caused by other agencies.

Another disease of unknown pathology which frequently follows accidents, with or without physical injury, is paralysis agitans. Mere tremor is, as one may say, a physiologic sign of fright, and usually soon ceases, but occasionally it persists without the addition of any other symptom. Sometimes there are added, in slow progression, all the symptoms of shaking palsy. The tremor may appear first in the injured extremity if the trauma has been a local one.

TRAUMATIC NEUROSES FROM THE STANDPOINT OF A SURGEON.*

ARTHUR DEAN BEVAN, M.D.
Professor of Surgical Anatomy and Associate Professor of Surgery, Rush Medical College, University of Chicago.
CHICAGO.

I feel honored by the invitation of this Section to discuss the subject of traumatic neuroses from the standpoint of a surgeon. I am very glad of the opportunity of doing this, because the subject is one in which I have been interested for some time, one which I have had unique and large opportunity of studying, and one upon which I have formed some definite opinions, opinions which are not widely known or accepted by either the general practitioner or the neurologist; opinions which I am confident will eventually be recognized, and which I consider of much practical value. The unique opportunity of studying traumatic neuroses to which I refer was the study of a train wreck in which the conditions were such that more than two hundred and fifty people were subject to the same amount of violence and the same condition capable of producing mental shock. I have already reported this wreck in detail in an article on real and alleged injuries of the spine. I shall not, however, hesitate to make free use of this material in this discussion, because this wreck furnished the rare opportunity of studying the subject in a purely scientific way, just as we would study and carry out a laboratory experiment. In fact, we could not plan out and carry out an experimental investigation of traumatic neuroses better than was accidentally accomplished by this wreck. I want to emphasize the point too that the study of this wreck was carried out, and the conclusion arrived at and submitted, in a purely scientific and non-partisan spirit.

I am not now a railroad surgeon, and have not been for years. I am not a medicolegal expert testifying for corporations. In fact, I refuse to testify in these damage cases, and do not do so except in the few cases where the law compels me to do so because of my having rendered professional services to the individual. It would be unnecessary for me to make this statement were it not for the fact that experience has shown that the salaried opinions of partisan railroad surgeons, just as the purchased opinions of neurological experts for plaintiffs, are of little scientific value and are justly discredited. It is as a student and teacher of general surgery, governed solely by a desire to learn the truth, that I investigate this subject and submit this report. My report is an indictment of the course usually pursued by the medical attendant in handling these cases. The one point which I especially desire to make clear is this: *The medical attendant, in the majority of cases, is more than any other factor responsible for the development and continuance of the condition known as traumatic neurosis.*

I say "majority of cases," because although I believe that in almost all cases the early and correct diagnosis and appropriate surroundings and treatment woud prevent the development of the condition, still there are many cases where the conditions surrounding the individual are beyond the control of the medical attendant, and a few cases where the nervous make-up of the individual is so susceptible and abnormal that the condition of traumatic neurosis will develop and continue in spite of the best environment and medical management. These cases, however, are rare and can not fairly be cited as argument against the position which I shall take. What do we mean by the term "traumatic neurosis"? In actual work the term is applied and misapplied to several classes of patients:

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

1. Conditions resulting from mental impressions made by injury or accident.
2. Cases in which there is a real injury of the nervous system following injury.
3. Errors of diagnosis such as a locomotor ataxia developing some weeks or months after an individual has sustained an injury or been in an accident.
4. Malingering.

We shall exclude at once from this discussion all but the first condition. Traumatic neuroses are abnormal conditions of the individual due to mental impressions accompanying, as a rule, slight physical injuries. This includes the two classes of cases of the authors of to-day, traumatic hysteria and traumatic neurasthenia. A few years ago most of these cases were classed as cases of concussion of the spine, or Erichsen's disease.

The condition, traumatic neurosis, is a mental state, not a disease with organic lesion. The mental state due directly to the injury and mental shock is transient, and under proper conditions and advice is soon recovered from, in the vast majority of cases. When the condition persists, the continuance is due to suggestions furnished by medical attendance, legal advisers, interested and symphatetic friends and relatives or auto-suggestions, with either money or sympathy in view.

For practical purposes, the cases of traumatic neuroses can be divided into two classes: 1, the medicolegal cases in which a claim for compensation exists; 2, the purely medical, in which no such element exists. As examples of the class in which the claim for damages does not influence the case I shall cite a few cases as examples.

CASE 1.—A young woman of intelligence, refinement, and wealth, was in a carriage, which collided with an electric car; she received a slight contusion of skin over the right patella. The occupants of the carriage, three women, were badly frightened by the accident, although neither the vehicle nor horses were injured. They continued a shopping trip afterward and then drove home. Upon arriving home the husband of the lady met them, was informed of the accident and was very sympathetic. Although the woman had walked on her shopping trip considerably after the acident, she now stated that she could not move the limb and her husband carried her into the house. A medical man was called. No injury to the knee could be discovered, but rest in bed was ordered. Later a surgeon was called, who advised a plaster splint; this was worn for some weeks. It was later removed, but the patient would not use the limb, although encouraged to do so. She stated that she had intense pain and that the whole limb was paralyzed. There was no swelling, and nothing abnormal to be found. Patient insisted on remaining in bed. Her general health was good, and she increased greatly in weight. This condition of affairs continued for about two years in spite of many different methods of treatment. Accidentally, it was found that when no one was about she would walk about her room without crutches. Suddenly she discarded her crutches and within a few weeks walked as well as ever, and there has been no relapse. I have seen five or six very similar hysteric knees, and cite this case as an example of a class. I feel confident that had the condition been early diagnosed, that had no plaster splint been employed, and had the medical attendants and consultants bluntly informed the patient that there was nothing wrong with the knee, that no treatment was required, that she should use the knee as usual, the condition of traumatic neurosis would not have developed.

CASE 2.—Mrs. A. B., a woman of 40, sprained her ankle. When I saw her three years later she had not walked a block without crutches. Her husband was satisfied that it was largely nervous. The injured limb was distinctly smaller than the good leg, both calf and thigh measuring more than an inch less. She complained rather bitterly of the pain and assured me that she could not walk. I told her that I would examine the foot with the X-ray. I found nothing abnormal. I gave her definite directions about walking a certain distance, and increasing this each day, and assured her that within a month she would be walking without difficulty. I advised massage and told her that within three months the limb would be as large as the other. I saw her again in about two weeks; she was walking naturally, and much to my surprise she told me that she considered the X-ray the greatest invention of the age, that it had cured her almost immediately, that she had not had a pain from the time the X-ray had been used.

CASE 3.—A woman, aged 40, about twenty years before had a lovers' quarrel, and sprained her ankle about the same time. The quarrel was not patched up and the ankle continued to trouble her. She refused to get out of bed and remained there nursing the ankle for seventeen years. She consulted many physicians. Her parents were very sympathetic and believed that she suffered greatly. One of her brothers was skeptical, and by watching her found that she walked about her room without difficulty when no one was present. At the end of seventeen years she fell into the hands of some christian scientists, who induced her to walk and for some months she walked well. Then, pleading as an excuse that she had again sprained her ankle, she took to her bed, refused to get up, and when I saw her, more than twenty years after the accident, she had been in bed for about three years after her *apparent* recovery from the christian science treatment.

I cite this case as a very extreme one. The history demonstrates that the individual had a peculiarly susceptible and abnormal brain, undoubtedly a sprained ankle or a lovers' quarrel might, with an abnormal brain, be the starting-point of insanity; in this case they were the starting-point of a traumatic neurosis lasting twenty years.

CASE 4.—As an example of the great care which should be employed in preventing an error in diagnosis in these cases, I want to record a mistake which I have made.

A woman, aged 58, slipped on the sidewalk and fell, striking her right hip. She was brought to my service at the hospital two weeks later, stating that she could not use the hip and suffered great pain. She was unquestionably neurotic. I suspected fracture of the neck of femur; but measurement showed no shortening, although it was not very satisfactory, because she was very stout, was about five feet, four, and weighed over 200 pounds. I examined her under chloroform, moved the limb freely, but could find no evidence of fracture. I informed the patient's daughter that I could not find anything wrong with the limb and that I believed it as a case of traumatic neurosis and han
Later, I obtained an X-ray picture,
tinctly an impacted fracture of nc
shortening.

Case 5.—As a sample of how an error of diagnosis might develop a case and how many of these cases of traumatic neurosis can be nipped in the bud, let me cite a recent experience. A young woman, aged 22, while traveling from a southern state to Chicago, to attend a university, sustained an injury of her chest in a railroad accident. In the same accident several people were killed and a number badly injured. She was examined by some local physician at the time, who believed that he found that her breast bone and several ribs were broken. She was put on the train, and sent to the hospital in Chicago, where she arrived forty-eight hours after the accident. My assistant examined her and believed from her history and complaints of pain that the sternum and ribs were broken. He put on the chest a tight, wide adhesive-plaster jacket. The next morning I saw the patient; she was breathing very rapidly and shallowly; she had an expression of great anxiety and suffering. I removed the adhesive plaster and examined the chest carefully. I found no fracture, lungs normal, breast normal. I ordered her to get up, and she found to her surprise that she could do so. I assured her that she was all right and would have no further trouble. Two days later she began her course in the university.

As examples of cases in which a claim for damages enters as a factor I shall cite the cases occurring in the wreck already referred to. The conditions under which this wreck occurred were the following: A long passenger train containing two hundred and fifty-six passengers, trainmen and four tramps, was crossing a trestle, twenty feet high and a half mile long, at the speed of twenty miles an hour. Suddenly the engineer blew the whistle and put on the brakes. For some reason unknown, the engine plunged through the trestle, which collapsed like a pack of cards, and let the entire train fall twenty feet. All the cars except the mail and express remained in their proper position and relation to each other. The accident occurred at 8 p.m., when every one was either standing or sitting. The result was that these people were practically all dropped twenty feet, striking on their feet or buttocks, with the additional force furnished by the sudden stoppage of the train running at twenty miles an hour. It was several hours before relief reached the wreck, but it was then systematically handled. The extent and character of the injuries in each case were noted and temporary treatment and dressing employed. The injured were then taken, part to a city hospital, and part to a country hotel.

Of the two hundred and fifty-six people in the train at the time of the accident, one hundred and twenty-three were injured; of these four were killed outright, and two subsequently died as a result of their injuries. The wreck occurred at night in a sparsely settled country, and help had to be brought from a considerable distance. All of the people were completely and thoroughly demoralized when the relief train arrived. It was necessary to carry forty of them on stretchers to the relief train. It was fifteen hours after the accident before they were all comfortably provided for. I mention these facts to show that conditions capable of producing fright and great nervous shock were present. In analyzing the nature of the injuries we found that four people had been killed by crushing injuries, the exact nature of which we could not state, as no postmortems were made. Twenty-two people sustained fractures, six of which were compound. There was one dislocation of shoulder. There occurred eight incised and lacerated wounds, and eighteen sprains of joints, including ankle, knee, wrist and elbow. In six cases there was nervous shock without any accompanying physical injury, there were fifty-eight cases of contused injuries; two injuries of the eye; one internal injury, probably of both lungs and of abdominal viscera, which resulted fatally within fifteen hours. One hernia, one abortion, and one injury of the vertebral column and cord were reported. Later many of the cases made indefinite claims of injury to the nervous system, the specific claim being in the majority that of concussion of the spine. In twenty-four cases this claim was backed up by medical testimony.

In the settlement of these cases many cases of malingering were found, and frauds were detected in the effort to palm off an old injury or lesion as recent and produced by the accident; such as hernia, bunion, curvature of spine, or displacement of the uterus. Hair which was dyed at the time of the accident had turned suddenly white, etc. One instructive fact in connection with the accident was the ease with which the plaintiffs could obtain medical testimony in support of fraudulent and ridiculous claims.

There were but two gross injuries of the nervous system: one a temporary paralysis of the musculospiral nerve in a case of fracture of the shaft of the humerus, and in the other a gross injury of the spinal cord; this patient died two years later from a bladder-stone operation. In both of these cases the symptoms were definite and immediate, and at once recognized.

In our discussion the interest of this wreck centers on the twenty-four alleged cases of concussion of the spine, backed up by medical testimony. A few of these cases were cases of malingering, the majority were examples of traumatic neurosis. One point I would like to make clear in regard to the medical management of the injured in this wreck is that very few cases of traumatic neurosis developed among the injured in my immediate charge, and those that did develop were entirely well in four weeks. The cases that persisted were in the hands of medical men who believed that the patients were suffering from concussion of the spine, or some other obscure but serious injury to the nervous system, and they had informed the patient and friends of this fact. These physicians were more responsible for the condition than was the accident. I am positive that, had I had each one of these cases in a private room at my hospital, and had the item of compensation out of the way, not a trace of the nerve shock would have remained at the end of a few weeks, and that all of them would have recovered their normal equilibrium. In no cases can the well-posted physician be of as much service, and in no class of cases can the ignorant physician, the partisan physician or neurologist, be of as much injury as in cases of traumatic neurosis.

The following is a very brief sketch of the twenty-four cases of traumatic neurosis developed in this wreck:

Case 1.—A woman, aged 45; no evidences of external injury: claimed injury to back; paralysis of right upper extremity, and that her hair turned suddenly white within a few weeks after accident. Claims severe nervous exhaustion, and permanent disability. A settlement was made and recovery soon followed.

Case 2.—A man, aged 25; no evidence of external injury; claims concussion of spine and refuses to leave room. He uses crutches, submits medical opinion that he is permanently injured; settlement was made and recovery followed.

Case 3.—A woman, aged 28, sustained fracture of rib; claims concussion of spine and permanent injury. She remained an invalid until settlement, and then recovered rapidly.

Case 4.—A man, aged 40, with real injury, bruised leg; claimed concussion of spine, paralysis and permanent injury. He remained an invalid until settlement, then recovered rapidly and returned to work.

Case 5.—This man had two ribs broken, claimed permanent injury of nervous system, remained an invalid, and sued company for $20,000. Shortly before the trial the case was settled. He recovered and almost immediately returned to his business.

Case 6.—A man with no evidence of injury, claimed spinal concussion and permanent injury. He was suffering from rheumatism at the time of the accident, and was in search of a favorable climate to live in. He used crutches. This case was settled and the day the claimant received his check he traded his crutches at a drugstore for some toilet articles, and left the town walking without help.

Case 7.—A woman received a bruise on the chest. She was tuberculous and suffered great nervous shock, and claimed great injury of the nervous system. Three months later she stated that she had not slept since the accident, was weak, unable to work, had had hemorrhages from lungs, due, she claimed, to the injury. A settlement was made. She improved, returned to work and died two years later of consumption.

Case 8 and 9.—A man and his wife. The night of the wreck they stated to me that they were permanently injured. They went home, remained in bed as invalids for seven weeks with the most exaggerated symptoms of spinal trouble. A settlement was made, they left the same week for a short trip and returned entirely recovered.

Case 10.—A commercial traveler. No evidence of external injury, but great fright, typical traumatic hysteria. He was under my immediate care. Complained of intense pain in back and paralysis of lower limbs.

At the end of a week I picked him up in my arms and put him on his feet. I told him that he was making a fool of himself, that he was simply frightened and not hurt. He cried like a child. I held him up on his feet and in ten minutes convinced him that he could walk. He left the hospital within three weeks of the accident, the day the settlement was made. After he left the hospital he consulted a neurologist, who told him that he had concussion of the spine. He was badly frightened. He wrote to me and I referred him to a physician to whom I had written my opinion of the case. This physician examined him, encouraged him to at once resume his work, which he did. I have seen this man repeatedly since, and he is most grateful for the way I handled him, although he thought it rough at the time. His description of his condition is most instructive. As he expresses it, he was so badly frightened about himself that if he had been told that he had a serious spinal injury he is convinced that he would have become a chronic invalid.

Case 11.—A man with sprained ankle claimed permanent injury of the nervous system; remained an invalid; claimed loss of power in injured limb. A settlement was made; he recovered and returned to work after drinking up the money.

Case 12.—A man, with sprain of ankle, claimed permanent injury of nervous system. Recovery after settlement.

Case 13.—A man, with contusion of chest claimed fracture of sternum and spinal injury; stated that he had lost his memory; had great general weakness; inability to work, loss of eyesight, and permanent nervous injury. He remained an invalid for many months, until settlement was made, and then recovered and returned to his work.

Case 14.—A man, with lacerated wound of nose and forehead claimed he had had fracture of the skull, concussion of spine; resulting loss of memory; impairment of eyesight, and permanent injury of the nervous system. The case came to trial. The jury gave a reasonable verdict. The money was paid; claimant recovered and resumed work.

Case 15.—A man, with contusion and laceration of face and shoulder; claimed spinal injury and permanent invalidism. Jury gave a verdict for plaintiff. The case was settled, and man recovered and resumed work.

Case 16.—An old lady, having great nervous shock, with stiffness and soreness after the accident, and no extended injury; claimed fracture of the spine, and submitted as evidence of such, an old spinal curvature; claimed injury of the spinal cord and permanent invalidism. Case was settled and recovery followed.

Case 17.—A girl, aged 20, having nervous shock, with no evidence of traumatism, claimed spinal injury and permanent invalidism. She remained in bed until settlement was made. She then recovered and returned to her home.

Case 18 and 19.—A man and his wife, with no extended signs of injury in either case. Both claimed spinal injury and permanent invalidism from the very night of the wreck. Both had had medical educations. The woman was very hysterical; the man was of more than ordinary intelligence. They wanted $30,000 each. Both became chronic invalids, most exaggerated pictures of traumatic neurosis. The woman claimed a fracture of the spine. She wore a plaster jacket for many weeks, putting it on, however, two months after the accident. The man took large doses of chloral and morphin, and within a short time looked like a physical wreck. They continued this state of thing for a year and a half. They consulted many neurologists and accumulated a vast amount of medical testimony as to their condition. About a year and a half after the accident their claims were settled out of court. Before this neither of them had done any work. They at once resumed work.

These were cases of artificial and induced invalidism. The people were intelligent and apparently honest. They were cases which were pronounced by some of our best neurologists as cases of spinal concussion, by others as traumatic neurosis. Yet there can be no question that it was in the power of an intelligent physician, and within the powers of the patients to have prevented the development of the condition, and the patients could have resumed their former occupations immediately after the accident.

Case 20.—A young woman, with great nervous shock, but no evidence of external injury, claimed at first on the advice of her physician, a traumatic anteflexion of the uterus.

The matter was submitted to me and I informed her lawyers that the claim was absurd, and asked them to submit it to three gynecologists. This was done and the three gynecologists agreed with me. Then the claim of spinal concussion was substituted. In the trial she developed the usual picture of traumatic hysteria, and had an abundance of medical testimony to back up her claim. She received a verdict. The case was compromised, and she recovered.

Case 21.—A man, with no evidence of external injury, traveled two hundred miles the day following the accident. When he returned home he felt sore and stiff.

His wife sent for the family physician, who told him that he had Erichsen's disease, that he must remain in bed five or six weeks and keep perfectly quiet. He was put to bed and given large doses of bromid and chloral, and external applications were made over the vertebral column. The man was ignorant, and had failed in business a short time before the accident. The confinement in bed and the medicines affected his general health, and he lost strength and weight. Three months after the accident I saw the patient. He stated that his mind was affected and that his lower limbs were partly paralyzed. I lifted him out of bed, and persuaded him to walk about the room with my assistance. I informed him that he must get up and take exercise, that he had no injury, and that if he chose he could be entirely well within a month. He looked at me and said: "[illegible] v doctor tells me that I am permanently injured. [illegible] that I am not hurt at all; whom shall I b[illegible]" [illegible] six months of the time of the accident [illegible] trial. The trial was hastened by his lawyers, who feared the man would die before its completion. The man was brought into court on a stretcher. Various tests were applied by experts for the plaintiff, as the dynamometer, the esthesiometer, electricity, etc. It was claimed that his spinal cord was permanently injured. He received a large verdict; this was paid. Within a few months he went to Germany, returned within a short time and resumed work, chopping cordwood.

Case 22.—A woman, having sprained ankle, claimed gross injury to vertebral column, and permanent invalidism.

She submitted as evidence of gross lesion of vertebræ, a prominent and irregular spinous process in the lower dorsal region. This claim was not made at once and the conditions following accident eliminated the possibility of fracture of the spine. Later, the claim was made that she had beginning Pott's disease, resulting from the injury. She wore a plaster jacket for some weeks. Still later, the claim was made that she had sustained some serious injury to her pelvic organs, which had resulted in cessation of menstruation. This, however, proved to be due to pregnancy. A settlement was made, she went on to term, gave birth to her child and recovered entirely.

Case 23.—A woman with sprained elbow, claimed permanent injury to her nervous system. Claim was settled and recovery followed.

Case 24.—A man, with contusion of the face, claimed gross cord and brain lesion and loss of right eye.

Had organic heart lesion. The eye was examined a short time after the accident by a competent oculist, who stated that the loss of eyesight was due to a lesion of old standing. Settlement was made, and recovery, as far as the general condition was concerned, followed.

Many of the other cases talked more or less of having sustained injury of the nervous system. Each of these twenty-four cases obtained and submitted medical opinions that they had sustained permanent injury of the nervous system. The subsequent histories showed that none of them had sustained permanent injury and that they all recovered. They were all cases of traumatic neurosis, with, in some cases, exaggeration and malingering added.

One interesting fact in connection with these cases is that the actual physical injuries were either slight or entirely absent. These twenty-four cases were the only ones of traumatic neurosis developed from this wreck. The individuals who sustained severe injuries did not develop the condition of traumatic neurosis.

The conditions were most favorable for the then so-called concussion of the spine, the traumatic neurosis of to-day. Out of the 250 people, 123 were injured, and 6 people were killed or died as a direct result of their injuries. Among the many injuries sustained, there were but two of the nervous system, one of the spinal cord and one of the musculo-spiral nerve. These were at once recognized. The twenty-four cases, above detailed, were not injuries of the nervous system, but mental states due to injury and later suggestions, such as I have previously described.

I would submit the following conclusion arrived at from the clinical and medicolegal study of about two hundred cases which I have had the opportunity of studying.

1. Real injuries of the nervous system present positive and immediate symptoms.

2. Those alleged injuries of the nervous system, without positive and immediate symptoms of gross lesion are either cases of malingering or abnormal cerebral states, traumatic neuroses, or a mixture of the two.

3. Traumatic neuroses are the result of two factors: 1, a brain readily affected by suggestions; 2, suggestions furnished by an accident with or without injury to the individual, suggestions furnished by sympathetic care or a craving for sympathy, and lastly and of greatest importance, suggestions furnished by medical attendants.

4. To establish a diagnosis requires the immediate and sometimes protracted observation of the patient, as in the study of any psychosis. The supposed refined means of diagnosis, as the dynamometer, esthesiometer and electricity, are seldom of value and are often of positive harm as suggestions to the patient.

5. These cases recover rapidly under proper surroundings and advice when the continuing causes are removed. Recovery may be indefinitely postponed under improper surroundings and advice.

6. No secondary degenerations of the nervous system follow traumatic neuroses. The pathologic conditions due to an old standing traumatic neurosis are the degenerations of disuse and the general deterioration of the individual from confinement, lack of exercise, dejection, etc.

7. The subject of traumatic neuroses will not receive its proper place until the medical profesion recognize their responsibility in the development and continuance of these conditions and until proper means are provided for the punishment of malingerers and their alleged medical experts.

I add a few words in regard to treatment: After definitely establishing a diagnosis, we should handle these patients without gloves. Have a frank, honest talk with the patient alone. Tell him to throw away the crutches, to go back to work. If the general condition is bad give him a few weeks, or even months, of exercise, and possibly change of climate. Tell him that there is nothing the matter with him; that the trouble is imaginary, is in his head and not in his feet or back; that if he will believe you and make the effort he will be perfectly well in a short time. Tell him that the constipation and hemorrhoids, the headache and tired feeling are due, not to the accident, but to his voluntary confinement. Outline definite course of treatment to be followed, a cold bath in the morning and exercise at certain definite times during the day.

If you handle your patient in a perfectly frank, open way, one of two things will happen. You will either cure him at once or prevent the development of the condition, if you see him early enough, or he will go to some other physician. If the other physician is as well posted and honest as you are and gives the patient the same advice, and if all the physicians consulted by these cases handled them in the same way, we should hear very little of traumatic neuroses. I believe, as I have already stated, physicians are responsible for the existence and continuance of the majority of these cases. I desire also to make a protest against the position taken by medical men generally on the witness-stand in testifying on this subject. Not long ago, I heard the testimony of two prominent neurologists on a case which they described as traumatic hysteria. They stated that there was no lesion of the nervous system, but that there was an injury to the higher nerve-centers controlling the will, which was far more serious than a gross lesion of the brain tissue. The jury gave a verdict for $20,000, and yet it is very evident that the man is suffering in no way from the accident. Lastly, I desire to protest against the usual method of neurologists and general practitioners of handling these cases of traumatic neuroses with gloves, diplomatically, which here means without a clear understanding between patient and physician as to the exact facts. The use of electricity and drugs, of refined means of diagnosis to discover and cure a disease which does not exist, the coaxing of the patient, are all apt to prevent a return of the patient to a normal condition.

In my own work, I have found the apparently more brutal and direct, and certainly more honest, method much more successful, and I would urge its general adoption.

MEDICOLEGAL RELATIONS OF TRAUMATIC NERVOUS AFFECTIONS.*

JAMES HENDRIE LLOYD, A.M., M.D.
Neurologist to the Philadelphia Hospital.
PHILADELPHIA.

The text for my present paper is the following case:

J. C., a colored woman, aged 53 years, in good health, without any personal history of alcoholism or syphilis, fell in the dark down a flight of stairs. She could not tell how she struck, or where she was injured, but she was immediately paralyzed in her arms, body and legs. There was no loss of consciousness. The accident occurred on April 9, 1899, and the patient was taken to a large general hospital, from which she was discharged unimproved in a few days for lack of accommodation. There was no history of her condition during these few days except that she was paralyzed as above mentioned. On April 14—five days after the accident—she was admitted into my wards at the Philadelphia Hospital.

On admission her condition was as follows:

Motion.—There was complete paralysis in all the extremities. Power was retained in the trapezius, sternocleidomastoid, and sternothyroid muscles, and in the diaphragm. The muscles of the chest were paralyzed.

Sensation.—Below a line indicated in the diagrams (Figs. 1 and 2) all modes of sensation were absolutely lost.

Reflexes.—There was a slight biceps and triceps jerk on the left side. Both knee-jerks were exaggerated. No ankle-clonus. No plantar reflex. This preservation of the knee-jerks is noteworthy.

Respiration was diaphragmatic and irregular. Inspirations were gasping, and not complete. There were no movements of the chest walls.

The bladder and rectum were paralyzed, and there was consequent incontinence of urine and feces.

Cerebum.—The mind was clear, the patient responding promptly to questions. The tongue was protruded in a straight line.

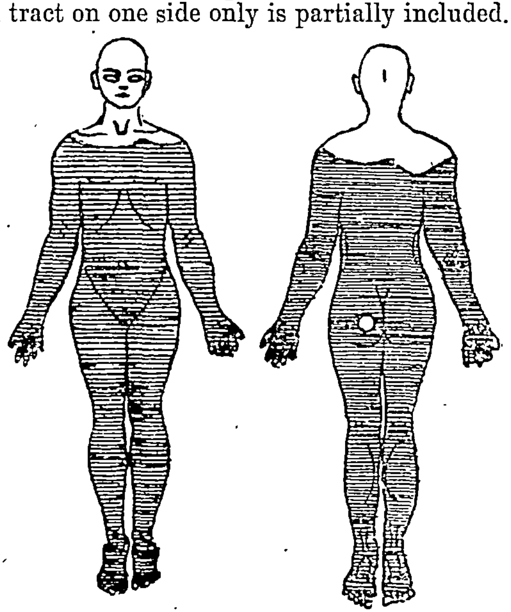
Eyes.—There was an old, probably congenital double external strabismus. It was in no wise related to the patient's condition. It has been made the subject of special study by Dr. Oliver.

There was no spinal tenderness nor deformity. There was no pain in the neck, and the movements in the neck, both active and passive, were good.

The patient's general health was good. She was a large, robust woman, without any disease of the heart, lungs, kidneys or abdominal organs[1].

With slightly fluctuating symptoms this patient lived for five days more. A slight return of sensation was noted in some limited areas, but it was only temporary and never complete. Paralysis remained absolute from the neck down. The knee-jerks were finally abolished. A bedsore formed on one buttock. The bladder and rectum continued paralyzed. Respiration became exclusively diaphragmatic. Thus, it is seen that the patient presented the picture of a total transverse lesion in the middle cervical region, with the exception of the fact that a slight return of sensation in limited areas seemed to indicate that the sensory neurons were not all completely cut off, and the further fact that the knee-jerks were not primarily abolished, as they usually are in a total transverse lesion. With such a picture presented to the eye of the clinician the diagnosis of a total transverse lesion would seem to have been justifiable. Certainly the lesion must have been an extensive one that could thus have abolished all the functions of the cord and caused the patient's death in a few days.

That the lesion was extensive the autopsy abundantly proved, but that it was extensive enough to account for all the symptoms was more difficult to demonstrate. In the diagram of the cord it will be seen that the chief lesion is a small hemorrhage invoving principally the anterior halves of the posterior columns, while the lateral tract on one side only is partially included.



Figs. 1 and 2.—Hematomyelia. Total anesthesia below the neck. Bedsore on left buttock.

The points which I wish to make in describing this case are that the amount of injury in this cord was much greater than a hasty inspection demonstrates or than the drawing shows. With a high power it was seen that the nervous tissue was the seat of edema, that nerve fibers had been compressed or even torn asunder, that minute hemorrhages were abundant and that the large ganglionic cells in the gray matter of the cord were swollen, disfigured and the seat of chromatolysis. In other words, what seemed at first glance like a very limited lesion was found on close inspection to be a most extensive destruction of the essential elements of the medullary tissue. Instead of a circumscribed hemorrhage in the posterior columns, which could not satisfactorily have explained one-half of the symptoms in this rapidly fatal case, there were extensive but microscopic changes involving practically the whole transverse area of the cord, and which explained perfectly the complete abolition of the functions of the cord.

Does such a case as this not more than support a theory? Does it not demonstrate that the abolition of function in these traumatic cases is a
necrotic organic changes in the neu

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] This case was originally reported in full in the Journal of Nervous and Mental Diseases, February, 1900.

porting and nourishing tissues, the glia and the blood-vessels? This case, to be sure, is an extreme one, but all the more on that account it permits a panoramic view of the various degrees of injury that can be sustained by the nervous system. All this injury is not gross and "organic" in the ordinary and old sense, but much of it is minute, almost insignificant, and even quite inestimable, and yet as truly structural as is the lesion made by the stroke of an axe.

In further pursuing this subject, we may now turn briefly to some of the clinical aspects of the traumatic neuroses. These affections may be divided into two main groups—neurasthenia and hysteria. I do not propose to traverse this whole clinical field, but merely to discuss some phases of it, and those merely which have to do with the medicolegal relations of these two diseases.

First, with reference to neurasthenia, I have long felt that more precision is desirable in limiting and describing this affection. This term should not be used as a disguise for other affections, and especially for hysteria. My contention is that in those cases of profound neurasthenia, in which the symptoms are persistent, the term "functional" should be wholly abandoned and the position assumed that in the light of modern researches the indications are that most if not all of these obdurate symptoms represent changes in the organic basis. We all know now, since the researches of Hodge and others, that the fatigue neuroses represent distinct changes in the neurons. We are no longer obliged to crave the indulgence of the metaphysicians while we borrow their terms to describe so-called functional effects which are without organic changes. Such distinctions should be abandoned to the schoolmen who still delight and amuse us with their claims that the brain is the "organ" of mind and not the embodiment of it. Surely, pathology, of all the sciences, should no longer be held in the trammels of these scholastic distinctions. On the witness-stand especially such distinctions are fatal. They are quite beyond the grasp of the average juryman, who is only too apt to think that if a disease is not a bodily affair, but only represents the deviations of an intangible function, it is not worth paying for in dollars and cents. I have had under my observation this last winter a middle-aged woman who received an injury and a shock in a smash-up between two trolley-cars. The injury was a punctured wound in the abdomen, which was bad enough, but the shock was far worse. This patient has practically been bedridden for six months, with a painful spine and a paretic leg, and that mental state of worry and discouragement which is worse than all, and her profitable business as a mantua-maker has been ruined. The question arises, am I obligated to describe such a condition as this as a "functional" neurosis? When I consider what I have seen in the cord which I have just described to you, I am quite prepared to contend that that painful spine, and that paretic leg, and that disordered brain, represent distinct changes in the central nervous system, which are none the less real because I have not had an opportunity of viewing them under a microscope.

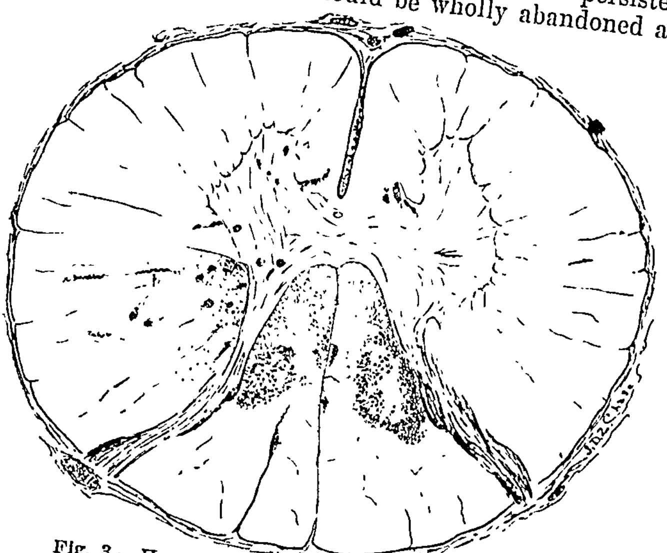


Fig. 3.—Hematomyelia. Fourth cervical segment.

With reference to hysteria, the same ground, I am convinced, may be properly held as in the case of neurasthenia. Of all the traumatic cases I suppose most men will concede that none are more common and puzzling than the cases of traumatic hysteria. That they are usually disguised in our courts under assumed names is a matter of common observation. It is believed with reason that to acknowledge to a jury that a case is one of hysteria is to give the case away. The prejudice against the term is not confined to members of the medical profession, but is widespread, especially among the more ignorant classes, from whom, as a rule, our juries are recruited. This fact has been curiously demonstrated to me by two cases in which I was engaged as an expert witness. In the first case a man, walking along the board walk here in Atlantic City on a wet evening, received an electric shock from a low-hanging arc lamp, with which the tip of his umbrella came in contact. As a result he had a typical hysteric paralysis of the arm. This limb was not only paralyzed for a year afterward, but was the seat of a blue edema, which gave it a badly damaged appearance. In this case the plaintiff's lawyer succeeded in convincing the jury that the affection was not hysteria, but that the nerves and muscles had been destroyed by the mysterious current, although it was demonstrated by the defense in open court that the nerves and muscles responded perfectly to both electric currents. In short, a verdict of $5000 was won by discrediting the diagnosis of hysteria. In the second case, a woman in Philadelphia, with an identical hysteric paralysis of her arm, caused by a blow from a falling sign, failed to obtain a verdict because apparently it was successfully shown to the jury that the affection was purely hysteria. These two cases illustrate perfectly the inconsistencies that prevail in our courts. Both cases were unjustly decided, because not decided in accordance with the facts. The man got more than his hysteria was worth, and the woman got less. Each deserved something, but justice failed to strike the average.

Why should not so-called functional disease which causes the disablement of a limb for months and even years be entitled to the same consideration as the more imposing "organic" affections? Why then should not hysteria, than which there is no more inveterate affection, be a damageable disease? I am not quite prepared to adopt the theory of the motility of the neurons, simply because it has not yet been sufficiently demonstrated. You all know, of course, what this theory is. The idea underlying it is that the neurons may display ameboid movements, and that by retracting or prolonging their dendrites and their neuro-axons with their arborizations, they may make or break contact in such ways as to cause alterations in functions. Thus, we may suppose that in a chronic hysteric paralysis the contacts are broken, and loss of function results. The same thing may happen in the profound anesthesias. The fact that mental impressions may operate to overcome and cure these various paralyses is quite explainable on such a theory, because we may suppose that a mental impulse would be potent to re-establish the lost contact. This theory has its attractions, but it is not yet sufficiently established in the domain of science for us to advocate it, at least more than tentatively. We may fall back, however, upon one of our original propositions, i. e., that no alteration in function can occur without a corresponding alteration in structure. If this alteration merely represents an alteration in nutrition it is yet a real thing, and not a metaphysical abstraction. With such views, I have for some time held that we should group the more permanent stigmata of the grand neurosis under some such term as "organic hysteria." Such a term is consistent with what we are gradually learning about the minute alterations in the central nervous system that underlie all the so-called functional diseases. Such changes are probably as real, though they may not be so permanent, as those that are caused in a neuron by the action of a poison or a process of degeneration. As I am not one of those who believe with John Locke, that it is as easy to conceive of mind without matter as it is to conceive of matter without mind, so also I can not conceive of a purely traumatic neurosis without a change in the organic structure. Let these distinctions be for scholars and transcendentalists, but as for us, in our medicolegal work, let us hold close to our material pathology.

PROGNOSIS AND TREATMENT OF THE TRAUMATIC NEUROSES.*

WHARTON SINKLER, M.D.

PHILADELPHIA.

The most serious problem which arises in connection with disorders of the nervous system, following railroad or other accidents, is what the outcome will be. The first question asked of a physician when called in to examine a case of traumatic neurosis, either by the patient himself or the corporation by whom he is called, is, whether the patient will recover, and if so, in how long a time. The prognosis in the traumatic neuroses depends upon a number of circumstancess and conditions, and first of all we must determine what is meant by the "traumatic neuroses". Different writers on this subject seem to have views somewhat at variance. Some —for example, Oppenheim and Strümpel—consider the traumatic neuroses as a separate class of nervous diseases, making a distinction between them and traumatic neurasthenia and traumatic hysteria. At the present day, however, it is generally considered that the traumatic neuroses include all of the diseases of the nervous system, either functional or organic, which result from accidents, either through actual injuries or from shock. Of course, in making a prognosis in these cases, the character of the disease, whether organic or functional, is to be taken into consideration, and above all, the length of time for which the affection has lasted. The previous health of the patient or the existence of a neurotic diathesis has much influence on the outcome of nervous disorders following injuries, and heredity should always be inquired into. It is therefore of prime importance to inquire closely into the previous health of the patient and the question of neuroses in his parents or near relatives. The surroundings and influences which are brought to bear upon the patient must also be taken into account in giving an opinion as to the question of recovery. What probably exerts as much influence as anything else on the condition of a patient suffering from traumatic neurosis is the question of litigation. In nearly all cases of injuries from railroad accidents, or those in which corporations may be held responsible, the patient at once seeks compensation for his injuries. He is encouraged in this by his friends, and by lawyers who are only too eager to work up a case. The patient becomes intensely self-centered, and all of his symptoms are dwelt upon and magnified. As long as litigation is pending, little or no improvement takes place, but on the contrary, the patient becomes more neurasthenic and hysteric. The questions of his counsel and examining physicians are liable to bring up new symptoms, and like all neurasthenics and hysterics, suggestion may develop features which had not before been thought of. It is therefore impossible to prognosticate as to the future of a patient with traumatic neurosis until damage suits are put out of the way.

The question as to whether a patient is simulating or not is a very serious one, and requires careful and thorough investigation. Most neurologists hold that simulation is rare, but that exaggeration of all of the symptoms is frequent. On the other hand, railway surgeons believe almost universally that simulation is very common, and that traumatic neurosis is, in the main, an imaginary disease. The truth, as usual, lies between the two extremes. Undoubtedly there are many cases of simulation met with, but they are not very numerous; and it is undoubtedly the case that exaggeration of all the symptoms in cases of traumatic neurosis is very common, whether there be or be not litigation in view. The opportunities for proper treatment will have much to do with the prognosis in such cases, and, after all, we may be justified in giving as hopeful a prognosis in cases of traumatic hysteria or neurasthenia, with favorable conditions for treatment, as we would in a case of the same disease where trauma had played no part, provided always that litigation and damage suits are set aside. The extent of hysteria and neurasthenia, and the length of time which the affection has lasted, must be taken into consideration. As a rule, a case of well-marked neurasthenia or hysteria, following injuries, will not get well until after two or three years of careful and thorough treatment under favorable surroundings. The prognosis in traumatic hysteria is not so hopeful as in neurasthenia, and the contractures and anesthesia may last for years. Traumatic lumbago is often persistent for years, and may leave the patient with a permanently weak back. Cold or strains may cause a return of the symptoms after a long interval of apparent health.

Treatment: It is of the first importance that treatment shall be begun as early as possible in these cases. The longer a case goes without treatment, the more difficult will be its cure, and it is as equally important to eliminate, as far as possible, the influence of litigation during the progress of the case. The effect of frequent examinations by experts and conferences with friends and counsel in regard to a damage suit, by keeping the patient harassed, aggravates the disease from which he is suffering, and creates a condition of expectancy which counteracts the results of [illegible] atment of organic neuroses arising [illegible] differ from that of the same disease not dependent on injuries. The treatment of traumatic neurasthenia and traumatic hysteria is best conducted by means of "rest treatment." Prince[1] says: "The rest cure, except so far as it secures isolation and has a mental influence, is illogical and useless, and aside from a certain class of cases, is not to be recommended." All that he has to offer, however, as better treatment, is in the line of mental therapeutics. He says that the physician should explain to his patient that his trouble is either neurasthenia or hysteria, and that he must exercise self-control and get rid of his pains, hyperesthesia and other distressful feelings by realizing that they are not real. He suggests hypnotism, the use of static electricity and hydrotherapy. On the other hand, almost all other writers on the subject are agreed that the treatment which promises the best results in these cases is the "rest treatment."

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

This plan of treatment is too well known to require special details. It is only well to refer to the necessity for the thorough and radical carrying out of the treatment in every particular, in order to secure a successful result. It is also essential to bear in mind that unless the question of litigation is settled in some way, or is held in abeyance, it is useless to attempt to treat the patient, either by this means or by any other. It is often the case that a patient is brought to a neurologist for treatment, either in a hospital or elsewhere, and the fact that a damage suit is contemplated is withheld until after the treatment is over. The physician is then made use of to further the ends of the patient in securing damages. The fact that he has been obliged to resort to a prolonged course of treatment is used as an argument in his behalf, and the physician's experience in the case is drawn out on the witness stand. One should always be careful to discover, if possible, whether litigation is considered by the patient before beginning treatment.

Another troublesome feature in the management of a litigation case by rest treatment is that the medical friends and family physician of the patient are insistent upon visiting him, and even when one exercises the utmost tact in refusing these visits, he is liable to give great offense. In the treatment of a case of traumatic hysteria or traumatic neurasthenia, one should insist upon rigid isolation, and on complete rest in every detail being carried out. The patient should remain in bed, and should not rise even for the calls of nature. A thoroughly competent and trustworthy nurse should be employed, and one who can offer a certain amount of entertainment and occupation to her patient without causing him to make an effort himself. The nurse should make the patient's toilet, and in some cases should even feed him. The points to be attained are, improvement in the general nutrition of the patient, the building up of flesh, improvement in the quality of the blood, and giving entire repose to the overtaxed and overstrained nervous system. The length of time which the treatment should last, of course, depends on the severity of the case, the temperament of the patient, and the duration of the disease before treatment has begun.

The rest treatment is not an infallible cure for all cases of neurasthenia and hysteria, and in those cases in which it fails, a complete change of climate and mode of life is often beneficial. The seashore agrees well with cases of neurasthenia, and great advantage may be derived from sending the patient, with a competent attendant, to a quiet resort on the seacoast, where he can have boating, sailing and an outdoor life generally, with a moderate amount of exercise. In patients who are unable to afford a thorough course of rest treatment, and often we find that this is the case, partial rest treatment may be given, with advantage in some cases, at the patient's home. It is not often, however, satisfactory, and it is much better to insist upon hospital treatment in cases where the patient can not afford the expense elsewhere.

Hydrotherapy is of great utility in traumatic hysteria and neurasthenia, either as an adjunct to the rest treatment or alone. The systematic application of douches and baths improves the general health of the patient, and is a means of improving the tone of the nervous system. Where a complete hydropathic establishment is available, the patient should always be sent there. The usual regimen consists in the patient's remaining in the hot box at a temperature of from 130 to 150 until sweating is induced, and he is then given the circular, or so-called "needle" bath for a couple of minutes at a temperature of 110, followed by a temperature of 95, for the same length of time. This is succeeded by the Scotch douche, which consists in alternating douching of the spine with a temperature of 110 and 65, at a pressure of from fifteen to twenty-five pounds. The fan douche may be used instead of the douche of full force. If a regular bath establishment is not within reach, the douches may be used at the patient's home, by having effusions of hot and cold water alternately poured down the spine, and an extemporary douche can be devised by attaching a piece of hose to the faucet of the bath-tub. The drip sheet and wet pack are advantageous in cases where insomnia is a troublesome symptom. When other means fail, it is justifiable to use hypnotism, but this procedure is of very little permanent value and is not regarded with any confidence by the vast majority of American neurologists. Even in cases where through hypnotic suggestion there is disappearance of some of the hysteric phenomena, the relief is seldom permanent. We must remember that, even in cases where the patient is susceptible to hypnotic suggestion, it does not prove the absence of organic disease

Drugs are of comparatively little value in these cases. The so-called "nervines" and "nerve tonics" are of but small value. Of course hematinics are indicated, and arsenic and strychnia in small doses help to improve the tone of the nervous system, but we must depend more upon regimen and proper feeding for the improvement in the nutrition of the body than upon drugs. The bromids are especially disadvantageous in neurasthenia and hysteria. If insomnia exists, it is better to combat this with hydrotherapy and hygienic measures than to use drugs. If one must give a hypnotic, it is best to give trional or chloralamid in small doses. Traumatic lumbago requires absolute rest in bed, with the use of massage and electricity. In severe cases, the use of the plaster jacket is sometimes necessary. The application of galvanism to the tender region of the back is serviceable, and static electricity often does good. After a sufficient period of rest, gentle gymnastic movements should be used.

DISCUSSION ON PAPERS OF DRS. BURR, BEVAN, LLOYD AND SINKLER.

Dr. F. X. Dercum, Philadelphia—I expected to hear from the lips of a surgeon statements such as were made, but hardly such reckless statements. Certainly, if the most eminent medical men in the country testified in his experimental 250 odd cases, we are justified in assuming at least a position of doubt; these men are probably neither rogues nor fools, and it becomes a serious question as to whether we are to accept Dr. Bevan's sweeping denunciation of them. That persistent symptoms follow in cases of trauma in which no element of litigation is present, we all know. Such cases are constantly being placed on record. Some of the most persistent have been non-litigation cases. I am thoroughly in accord with Dr. Lloyd's position that these cases are not functional but are really organic; that there is some intra-cellular or other change; that something is wrong with the nerve cell if it ceases to act, or with the nerve-fiber if it ceases to conduct. The question is: Do these people invent the contraction or reversal of the color fields? Do they invent the stigmata of hysteria? It is absurd to suppose such a thing.

---

[1] American System of Practical Medicine, Vol. iv, p. 467.

It is perfectly true that justice is not always done in the course, but it is true that an average of justice is done; and I have not such a contempt for the jury as some of my brethren have. It is just such differences of opinion as we have seen here today which make it difficult for the layman to decide what is right. I have rarely met with cases in which the damages are greatly in excess; if so, the cases are appealed, or new trials are had, and a smaller verdict given. It is the exception too that large amounts are given; more often the amount which is given is inadequate to the actual injury sustained. I am fully in accord with Dr. Sinkler's views in regard to treatment, and I can also endorse his statement that the rest treatment does not always cure these people. Some of them are hopelessly injured.

DR. DANIEL R. BROWER, Chicago—I am glad that I had the privilege of listening to Dr. Bevan's excellent paper; no matter if we differ from him in his conclusions we must admit that he has made a very careful study of his cases. The members of the Section, generally, will agree with Dr. Bevan that many cases of so-called traumatic neurosis are manufactured by lawyers and doctors, the symptoms being developed by the expectation of damages. If all physicians were as judicious in their management as the essayist, there would be but few suits for damages. There is, nevertheless, nervous disease; of a prolonged and intractable character, that is produced by trauma. The case presented by Dr. Lloyd is in point and exceedingly instructive, demonstrating that death may occur in a traumatic neurosis, with pathological lesions, that seemed to be trifling.

Dr. Bevan's interesting paper has distinctly set forth the fact, which we all recognize, that many of the cases can be cured by suggestion.

DR. SAYRE, New York—I for one must say that I do believe in the existence of traumatic neurosis, and I have seen these neuroses simulate very closely surgical lesions. I have in mind one case that received a violent fall, was supposed to have injury of the spine, was treated in one city for six months for Pott's disease, in another by means of a plaster jacket for about a year, in another with a spinal support, and in a fourth with another plaster jacket, and who presented almost a typical case of Pott's disease of the spine. One leg was very much atrophied, and the patient was hardly able to move without assistance. I watched that case for a week or so before I came to a diagnosis, and it seemed to me that it must be something besides the spine. These symptoms had all come on immediately after an injury; there was no question of litigation, as it was a runaway accident. I found that the patient had a retroflexed uterus, pressing on her sacral nerves, and on an operation being done, the atrophy of the leg disappeared, the pain on movement and the muscular contraction of her spine also disappeared. Four other men, whom you all know very well, of wide experience, had had her under observation for a period of about three years. That woman had simply a nerve irritation from pressure, and when that pressure was relieved the atrophy of the leg passed away.

I have seen another case of a woman who was working on a stamping machine that she drove with her foot, to punch button-holes or something of that sort, and she also developed a curious train of symptoms in the leg with which she was accustomed to work. A violent pain would occur in this leg and knee. Then a large blue swelling would occur, according to her statement. That knee became very tender; she said it was impossible to move it; it seemed to so much resemble inflammation of the knee-joint that one of our most prominent surgeons in New York opened that knee and, finding nothing, sewed it up again. It was concluded that she had an abscess in the head of the tibia, and it was suggested that that be explored. She would not allow this, and went to another hospital. She was referred to me by a colleague under the impression that it was a chronic inflammation of a knee-joint. I came to the conclusion that it was not an inflammation of the knee-joint, as the temperature of that knee was very much depressed below that of the other. The red bulbous swellings were also contraindication. I believe that this woman had an inflammation of the nerves of her leg, probably caused by her occupation. She was very neurotic. I put her leg at rest, I found that she had an infantile uterus; this I stretched and faradized, and kept her at rest for some months, and then gradually gave her permission to walk slowly; I toned her up and kept control over her mind at the same time. I took her out of the hospital and kept her under my personal control.

I think that there is no question at all in these cases that the personal element is very largely responsible for the rapidity with which you cure your patients. If you allow your patients any laxity they are very apt to relapse. This patient has at the present time an absolutely perfect leg and knee, although if she does too much with it she is apt to have twinges of pain.

DR. CHARLES K. MILLS, Philadelphia—This subject is too important a one not to be thoroughly discussed. Naturally the attention of the neurologists here would be directed to the statements made by Dr. Bevan, the railroad surgeon, and I think with Dr. Dercum that the statements, or at least the sweeping conclusions of his paper, should not be left to pass unchallenged. For many years I have had a very large experience in litigation cases. This experience has not been solely obtained in connection with the plaintiff; perhaps more frequently I have been employed by attorneys for the plaintiff than for the defendant, from the very nature of the case, and from the fact that most corporations have particular physicians in their employ. I have, however, somewhat frequently testified for corporations. I have even appeared in court in two cases on the same day, in one of which I was a witness for the railroad and in the other a witness for the plaintiff in a case against it. More than once I have examined cases for the claim agent of a railway at the same time that I have had cases for the plaintiff against the railway. I mention these facts merely to show that my position is not taken because of any particular prejudice or bias which has been obtained by the manner of my employment as a medical witness or medical adviser. The result of my experience is that, while in some, and perhaps many, cases exaggeration is present, and while also there are a few cases of absolute fraud and simulation, yet in the vast majority there is some genuine basis in real disease of the nervous system or some other part of the body for the claims which are made. This may not always be the disease which it is supposed to be by the physicians who are in attendance or the physicians who are called in either to assist the side of the plaintiff or the side of the defendant. It is important to study the statements made by our friend, the railroad surgeon, in the light of practical experience of this kind. His statements, as I recall them, were that there are very few cases of real injuries to the nervous system, even in accidents of so serious a nature as that to which he alludes, or at any rate in a certain percentage of the cases which he presented—not in the whole number. Above all, he made the statement, which is a serious one, that the cases were made by physicians who were called in to examine them and who were called in to testify. I think this last statement, in particular, is one which should not go unchallenged. I do not know what they do in the West in these cases, but I know the course which is followed in this part of the It happens that the railroad surgeon is not a patient who is alleged to have, or is supposed to have, some disease of the nervous system. If he is competent he will be likely, if he is an honest man—and usually he is—to make some statement as to the real state of affairs. The railroad surgeon sometimes passes by the real symptoms which are present, or he adopts the "brutal" methods which have been recommended in the paper we are discussing. The cases are forced to a speedy settlement, and are supposed to be cured. Often they are supposed to be cured for reasons which are wholly insufficient, because, for instance, the patient gets married, or goes on with his business, or does not present any active symptoms, or at least any symptoms which would be open to an ordinary observer. In many cases I have known such patients, years after litigation was ended and settled, to still present serious symptoms.

Dr. William M. Leszynsky, New York—I think that every experienced neurologist will echo the sentiments of Dr. Mills and Dr. Dercum in regard to this matter. It has always seemed to me that the railroad surgeons examine these cases with the preconceived notion that all are frauds, and, consequently, the diagnosis is often erroneous and results in unnecessary confusion.

I have recently seen two patients and read the reports of the railroad surgeons, which were submitted to me by the railroad companies, in order that I might confirm or negative the official conclusions that these claimants were frauds. Both instances were perfectly clear cases of traumatic hysteria, with all of the stigmata, and many of the symptoms with which we are so familiar. If the railroad companies which employ surgeons at an annual salary would also employ a neurologist such errors in diagnosis would be avoided. The methods, recommendations and conclusions of the reader of the paper are, in general, impracticable and unscientific, and are not in consonance with accumulated neurological experience.

Dr. W. T. Bishop, Pennsylvania—My own experience as a witness in behalf of corporations is that they want you to tell the truth before and after going on the witness stand. I saw one accident in which some forty odd persons were injured, and saw every case. There was one lady who claimed to be very seriously hurt; I found that she had a very large button on her petticoat, and she imagined she had been hit in the back.

Dr. A. E. Sterne, Indianapolis—It strikes me that this question can be looked at from several sides judiciously and wisely and with perfect honesty. I am much of the mind of Dr. Brower when he says that the way things are done in the East is very different from the Middle West. I believe that a large part of the conditions that arise in these patients are bred and born of circumstances. It depends very often on the surroundings, and largely on the locality in which a person lives as to whether or not he will put his case in legal hands or whether he has any choice in this matter whatever. I know that in all parts of Indiana there are lawyers in every town, and several firms of lawyers in the city of Indianapolis, who make it a point the moment they hear of an accident to investigate it and step in and take charge of the case if possible. Those men study up these questions, usually not with the acumen of a neurologist, and usually a neurologist can trip these men up, but ordinarily they instill into these claimants for damages a certain amount of ability to do and say things as they would be done and said by patients with these injuries. As far as I am personally concerned, I try to keep out of every damage suit, whether it is for a corporation or a private individual. Further, there are a great many of these cases in individuals who are undoubtedly injured, and permanently injured. Neurasthenia, whether we meet it simply or traumatically, is certainly a loss of power of the nerve cells. Fright causes conditions outside of accident; why not then in accident? Every year the question of expert medical testimony comes up in almost every society, and we very seldom come to any definite conclusions; in fact, we can not well do so inasmuch as the law allows so much latitude in such matters. Under all circumstances this question must be very carefully handled. It would certainly be a gross error to declare that every damage case for injuries received is fraudulent, or even suspicious, but it is just as well to bear in mind the apparent necessity which compels a claimant to remain invalidized as long as litigation is in progress.

Dr. David I. Wolfstein, Cincinnati—From the tone of some of the arguments made here one might think there was doubt as to the existence of the condition known as traumatic neurosis. I certainly thought, notwithstanding the rather brisk argument of the surgeon, that traumatic neurosis was an accepted and well-defined state. Even after the surgeons have eliminated malingering, and the ills born of pending or intended damage suits, there are certainly many cases which are deserving of the name and which I fancy would defy most obstinately the essayist's methods.

I should very much like to have heard brought out in the discussion more exact information as to classification. Shall we differentiate between traumatic neurosis and traumatic hysteria? Shall we reserve the term neurosis for those cases which do not present any hysterical stigmata? Furthermore, it seems wise to me to limit the term "traumatic neurosis" to such cases as do not present palpable and visible lesions, at least of grosser nature. For this reason, with the greatest respect for Dr. Lloyd's remarks, I do not think a case such as he quoted should be made to bear upon this subject. I doubt if a case so acute, so rapidly fatal and with such grave symptoms, presenting what seems to me to have been small hemorrhagic foci, is properly a case of traumatic neurosis. I think traumatic acute myelitis would probably better apply.

Of course, we must continue to believe that every pathologic condition has underlying it a corresponding anatomic, or molecular alteration of tissue, in the nervous system, as elsewhere. However, I fear we are accentuating too enthusiastically the advantages of the Nissl, and even the Marchi, method in diseases of this order.

Dr. Richard Dewey, Wauwatosa, Wis.—I regret that Dr. Bevan did not remain to hear the discussion of the paper, and to sum up in answer to the objections raised. The paper is one which I heard him read several years ago before the Medicolegal Society of Chicago, and it seems to me desirable that the secretary of the Section be invited to request him to bring his paper down to date and to report at the meeting of this Section next year, giving any further light that may be possible on the cases which are reported as they stood several years ago. The remarkable fact of all the patients recovering that were under his care, and none of those, or apparently very few of those that were not, would make it seem that there was something fallacious in that. It is possible that the patients, as has been mentioned here, who apparently were well, might have many symptoms remaining of the neurosis from which they suffered, and that the apparent recovery was not merely the result of their being under the care of a particular physician.

Dr. Watson—I want to speak of the possibility of injuries being very slight, so far as external appearances are concerned, and yet develop very serious nervous disturbances, extending over years. I recall to mind a case of railroad injury, some eight or nine years ago, where there seemed to be but very slight injury, with recovery in three weeks' time, but after about five years she exhibited symptoms which were only referable to the accident; until she came under my treatment she was a hopeless invalid.

Dr. Nathan Herman, Baltimore—I notice that there is a tendency in this interesting discussion, the whole of which I unfortunately did not have a chance to hear, to make a distinction between psychoses and neuroses, between functional and organic derangements. I am one of those who believe that there is no functional derangement without an organic basis, and although, as in other diseases, the extent of the organic lesion may not comport with the functional disturbance, or vice versa, still I believe there is always some organic disturbance as the basis of the trouble. If this is difficult to find post-mortem, as we know it is, how much more difficult ought we expect its discovery to be ante-mortem.

I will cite a case of mine which will at least serve to illustrate the reality of the disease. It is the case of a youth of 20 years of age, who, in consequence of a slight accident in connection with a cable car, developed a marked tremor, or rather jactation, of the right leg. He went the rounds of hospitals in various cities, becoming, with some remissions, on the whole gradually worse, and finally landed at the Hebrew Hospital, of Baltimore. When he came under my treatment his condition resembled very much that of paralysis agitans, and I so called it in a paper presented before the Medical and Chirurgical Faculty of Maryland. There was no possible reason why this youth should malinger. The case was finally cured by hypnotism, all other means having failed. It might be contended that the fact of the cure being effected by psychical means would prove the purely psychical nature of the case, but, on reflection, it appears not more unlikely that a pathological condition with an anatomical basis should be benefited by the exercise of psychic function than that a similar state of affairs in the so-called physical realm should be benefited by means of the exercise of physical functions, which, indeed, is a common occurrence. The success of the psychical treatment, therefore, by no means justifies the condition that a lesion did not exist.

DR. G. W. MCCASKEY, Fort Wayne, Ind.—It seems to me that there must necessarily be some sort of anatomic basis for the chronic functional disturbances of neurasthenia, although there are some things which appear very difficult to explain in harmony with this theory, among which may be mentioned the sudden development of symptoms in some cases. These anatomic changes are not, of course, supposed to be of a gross character, but relate to the intracellular structure of the protoplasm. Such changes may be the result of either excessive fatigue, autointoxication or traumatism, as in the cases of traumatic neurasthenia, the existence of which was pointed out long ago by Charcot. There are many elements in these cases connected with railroad injuries, the psychical ones being quite important, and I can fully corroborate the statement made that these cases, especially when concerned in litigation, practically always exaggerate their symptoms. Sometimes this is done consciously and at other times unconsciously, but always to the great detriment of the plaintiff in the eyes of the expert, the jury and the court.

DR. BARKER—It must be remembered that in all large railroad accidents there is a certain percentage of those who go on their journey and make no claim for damages, and yet who are injured seriously by shock.

DR. C. C. HERMAN, Pittsburg—One feature of these cases is that when a physician gets on the stand to testify he is put upon self-defense, as each lawyer is trying to obtain such answers from him as will strengthen his side of the case—questions of a double meaning, unanswerable until rearranged and answered separately. I think the author unnecessarily severe in some of his statements; also he seems to have little faith in either the ability or honesty of the neurologist. I have often seen faith limited by the meager knowledge of the subject. I am willing to endorse the essayist as a surgeon on the merits of his paper, but not as a neurologist.

THE CHAIRMAN—I believe that some misapprehension has arisen as regards Dr. Bevan's stand on this subject. I happen to know Dr. Bevan very well, have talked with him about the affections under consideration, and am sure he does not at all believe that these patients with traumatic neuroses or psychoses are simply simulators, exaggerators, liars and plunderers of the railroad systems. I regret that he could not remain to explain his position, but I think he did not make any statement approximating that idea in his paper. What he particularly meant was that if taken promptly after the accident, and then handled properly, the old chronic cases of traumatic neurosis, which he recognizes as a disease, would be obviated. I believe that that is a fair statement of Dr. Bevan's position as regards that particular point.

DR. CHARLES W. BURR, Philadelphia—It seems to me that a very large part of the discussion this afternoon has been used in breaking down an already open door. Certainly no one doubts the existence of traumatic hysteria. I do not know what Dr. Bevan meant to say, but certainly the whole implication of his article was that practically hysteria was another name for fraud. That was the moral most of us drew from his paper. Of course, men may pretend to have hysteria, as men pretend to have broken legs, but the reality of the existence of the disease is beyond question.

I was in hopes that something would be said on the other side of the functional question. Most of the speakers have assumed that hysteria has an anatomic basis. There is no known anatomic basis for hysteria. If by organic disease we mean a disease that, either to the naked eye or to the microscope, will show some change in which we can say, from the state of the organs in death, without any prior history, that the patient had that or the other disease, then we must say that hysteria is not an organic disease. The most careful study will not enable any man to say post-mortem that this was a case of hysteria. So long as that is true, we are bound to say that hysteria is a functional disease.

As to prognosis, I have had one case which lasted for twelve years, although it was settled three months after the accident. The patient is now a classical picture of hysteria, and will probably so continue until death. As to the possibility of disease, at first functional, becoming organic, a year ago I made an autopsy on a woman who had been an inmate of the Philadelphia Home for Incurables for fifteen years. She was sent there fifteen years ago with a diagnosis of chronic incurable hysteria. She was paraplegic, anesthetic, and had some special sense symptoms. Many very good physicians had examined her during the years of her illness, and all agreed that she had hysteria. I watched her three months out of every year for ten years. She did not change at all. Last year she died of Bright's disease, and post-mortem there was a diffuse myelitis of the spinal cord. Did that woman start out with a functional disease thirty years ago and finally end up with the organic disease, or was the disease originally organic? Of course, I agree entirely with Dr. Sinkler as to treatment.

DR. WHARTON SINKLER—In regard to the matter of bulldozing sick people, the fact that a person may be made by strenuous effort and insistence to get up and go about does not prove that he has no organic disease. It is a well known fact that a person having an organic disease, like a brain tumor or a myelitis, may, through hypnotic suggestion, be brought to do certain things. The fact that this has been done by the method which Dr. Bevan has suggested does not prove that his cases were simply imaginary.

PHYSICIANS AS SPEAKERS.

WILLIAM WHITFORD.

OFFICIAL STENOGRAPHER, AMERICAN MEDICAL ASSOCIATION.
CHICAGO.

Introductory Remarks.—The communication of thoughts by means of spoken language is an art that can not be acquired to any great degree of perfection except by long and continued practice. Some physicians are more highly gifted than others with facility of expression, and they are naturally endowed with the power of eloquence; but to none is it at all times an easy process to embody, in exact and appropriate language, the various trains of ideas that are passing through the mind. However distinct may be a physician's voice, however vivid his conceptions, he is often conscious that the phraseology at his command, particularly in public speaking, is inadequate to do them justice. He seeks in vain the words he needs, and strives ineffectually to devise forms of expression which shall faithfully portray his thoughts. He employs words and phrases either too general or too limited, too strong or [illegible] feebl[illegible] [illegible]hich suit neither the occasion nor the [illegible]

It has been said that physici[illegible] advantage in public speaking.

moned to testify in courts of justice, where their resources of expression may be taxed for hours. They are frequently placed on boards of education, on committees dealing with sanitary conditions, and on the common councils of cities. In meetings of citizens they are asked for their views on propositions affecting the public health, and, if successful in their professional careers, may be associated with the faculties of medical colleges. They are also members of city, county, state and national medical associations, where debate is had on papers read and questions relating to the rights, privileges, or standing of the profession, or regulations for the management of the organizations. Yet for such positions many, otherwise qualified, are unsuited because they have neglected the study and practice of free expression. Some distinguished members of the medical profession have deplored this lack and have urged upon medical students the importance of attending to the subject.

Voice and Pitch.—The pitch, intensity, and amplitude of a speaker's voice have much to do with the work of the reporter; in that they will greatly expedite his work or render it extremely difficult. A physician, in addressing a convention in a large hall, may pitch his voice so low that perhaps only one-half of the members can hear distinctly what he says, and it is largely guesswork for the other half to grasp his meaning. If a reporter be reporting the proceedings of a large association, as, for instance, the American Medical Association, and the members rise and speak from various parts of the hall, the pitch of their voice will play an important rôle for good or bad. The acoustics of a hall may be perfect, but if a physician's voice is improperly pitched, he will be imperfectly heard; and, in such instances, incorrectly reported. It is an irksome task for any reporter, no matter how acute his hearing may be, to report a physician who has a low-pitched, thick voice, coupled with a mumbling mode of utterance. On the other hand, the physician who takes cognizance of acoustics and pitches his voice in a much higher key, if he articulates well, can be heard in the remotest nook or corner of a large convention hall without apparently any unusual effort. A low-pitched voice, combined with rapidity and indistinctness of utterance, will worry most reporters. A physician with a tolerably high-pitched voice may be clear and distinct in utterance, yet excessively rapid in delivery. His clear-cut sentences may flow uninterruptedly at the rate of between 160 and 190 words per minute. Such a man can be reported with comparative ease by an efficient hand. Reporters sometimes have to report physicians with imperfectly attuned voices, who speak in a go-as-you-please fashion. Their sentences are diffuse, involved, and deficient in precision. The one who tries the mettle of the reporter is the quiet, easy, fluent speaker, who speaks just loudly enough to make himself distinctly heard, and pursues the even tenor of his way without a pause, without emphasis, without anything that can check the rapidity of his utterance.

It is a pleasure to report the masters of language, of tone and gesture, who possess voices remarkable for their volume and range and their capacity to express every shade of feeling and of passion of the human soul. Deep in tone, and perhaps melodious, such voices are magical in their power of controlling the feelings of those who listen to their varying cadences and exquisite modulations. The Rev. Joseph Parker said that the late Mr. Gladstone had "a rich, round, deep, expansive, melodious, grand voice." The voice of Henry Clay, we are told, had "an indescribable charm. It could ring out in trumpet tones, or it could plead in low, plaintive notes, which pierced and thrilled the hearer." The voice of Daniel Webster was "deep, rich, musical, flexible, and of prodigious volume and force." Mr. Lecky, in writing of O'Connell, says: "With an easy and melodious swell, his voice filled the largest building and triumphed over the wildest tumult, while, at the same time, it conveyed every inflection of feeling with the most delicate flexibility." On the other hand, Thomas Jefferson failed as a speaker simply for lack of voice. His voice became guttural and inarticulate in moments of great excitement, and the consciousness of this infirmity prevented him from risking his reputation in debate.

Wendell Phillips advised, for public speakers, a sustained conversational tone, a little elevated above the ordinary, with an effort at distinct enunciation. He advised, too, vernacular speech, even colloquial in tone.

A clear, distinct, far-reaching voice is undoubtedly a natural gift, although physicians, as speakers, can do much by training to acquire an agreeable tone. In reporting loud, excitable, inflammable speakers, I have met with difficulty at times in catching the exact words, owing to deficient enunciation or muffled syllables. Occasionally a great speech is delivered which seems to preserve in print some of the chief elements of its power; but in the vast majority of instances it is but the worthless remains which the most expert reporter can give of that which, in its utterance, so charmed or electrified the audience. Bright, Gladstone, Phillips, Clay, and other great orators understood the secret of how to pitch the voice so as to make it audible to everybody in a large hall. If the acoustic properties of a hall are good, the voice pitched in the right key will carry; if those properties are bad, the shouted words will be heard no better than if they were whispered.

As the possessor of a good, clear, penetrating voice, I may mention Dr. Dudley S. Reynolds, of Louisville, Ky., who usually takes a conspicuous part in the proceedings of the general sessions of the American Medical Association. A more powerful, rotund, far-reaching voice is rarely possessed by any public speaker. It is an organ-toned basso of unusual range and carrying power. Whenever Dr. Reynolds utters the words, "Mr. President!" in true oratorical style, in a general meeting of the Association, it is the signal for craning of necks and upturned faces. He commands attention at once. The same may be said of Dr. W. T. Bishop, of Harrisburg, Pa., who has a naso-metallic voice of wonderful carrying power. He likewise takes an active part in the general meetings of the Association, and whenever he rises to speak and the President asks him to announce his name and state, he exclaims, "Bishop, of Pennsylvania," with a trumpet ring of the voice that can be heard in the remotest nook of a large assembly hall.

The voice and manner of some speakers make those listening restless, weary and uncomfortable, even when the subject-matter of the address was valuable and of interest, the speakers themselves being usually entirely unconscious that the effect produced was so contrary to their aim. Doubtless, too, nearly all have at some time been made sensible how much of soul-stirring power may be communicated by the tones of the human voice alone, whether employed in speech or song, and I can appeal to the experience of many to witness that it is not so much in the words, however intense their meaning, as in the tones which convey them, that the soul's utterings are clearly recognized. The possibilities and results of a good voice can not be fairly estimated; they are too far-reaching; and it requires but little thought on the subject to realize that the direct benefits accruing to the possessor of a clear, well modulated voice are incalculable. The conversion of a poor, unpleasant voice to one of rich and musical quality discovers to its owner the energy of unsuspected forces.

The disadvantage of a weak voice or of speaking habitually in a feeble manner is the not being heard at all, or with difficulty. But a more subtle and pernicious consequence is that it reacts unfavorably upon the mode of thought and expression. While speaking too low is a fatal impediment, it is detrimental to speak too loud, for the reason that the ear is pained, the attention distracted, emphasis defective or excessive, the nerves of the hearers irritated, and if the voice be in any degree strained, it will be neither sweet, soft, nor agreeable. The consonants should be articulated distinctly, but not to the neglect of the vowels, in which inhere all the best qualities of the voice as well as its carrying power.

It is said that a medium pitch should be the basis of speech. From it one may rise or fall, according to intellectual and emotional requirements. Height and depth are necessary. Beecher said, "What a speaker most needs is to strengthen his ordinary conversational voice, without giving it a hard, firm quality; that is, without destroying its flexibility and power of adaptation to every mood." It is a fine art to be able to lower one's pitch. Some scream on to the end during an animated discussion from sheer exhaustion; others spasmodically fall to a low note, but immediately forget themselves and run up to the same pitch, vociferating until out of breath.

The acoustic properties of most auditoriums or convention halls are imperfect. But these defects generally have a physical cause which admits of being guarded against by the adaptation of the speaker's position and tone. Monotony of a low-pitched voice exerts a soporific influence over an audience, which no strength of thought nor beauty of language can wholly counteract; and if there be regularly recurring minor notes, the most startling expressions lose their power. Even to those who do not sleep the sounds bear no sense. The prime object of a speaker should be to make himself understood; and to this end sense should never be sacrificed to sound. A speaker should never use more force than necessary. If requested to speak louder, he should beware of raising the pitch of his voice; by a slight increase of volume on the same key he can make anyone, whose organs of hearing are not defective, hear distinctly. The groundwork of good speaking is the tone of lively conversation.

Vivacity is not force, yet many speakers, to evoke interest, use more force, when the only means of gaining what they seek is increasing animation. Dr. Henry Mandeville gives a distinction of supreme moment between force and vivacity. He says: "We should be careful not to confound force with vivacity. Force is strength, energy; vivacity is life, animation. Force has respect to the hearer, vivacity to the subject. . . . Force, to the verge of vociferation, especially if uniform, may be associated with dullness; vivacity never; and yet there may be great vivacity in speakers who have little force. . . . Force is under the control of the will, and is measured and regulated by the judgment; vivacity depends upon the feelings and their susceptibility of excitement from the progress of discussion. The one is therefore voluntary; the other involuntary. A speaker can command force at any time; but vivacity, if it comes at all, comes without being summoned or solicited. It appears only when the speaker begins to be interested in his subject; and as this penetrates and warms and absorbs him it grows apace independently both of judgment and volition."

The late Mr. Thomas Allen Reed, an eminent English reporter, says: "I have heard speakers laboring hard to make themselves clearly heard by a large audience, but to very little purpose; they have been speaking in their ordinary tone of voice, and straining every nerve after a distinct utterance; but their pitch has been too low. A very little elevation would have made them more audible with much less exertion. I have known speakers with extremely weak voices make themselves well heard in large rooms by simply attending to pitch and clear articulation." A loud voice may be a very indistinct one, sometimes indistinct because of the loudness. The essence of distinctness is a clear, crisp articulation. With some speakers the vowels absolutely drown the consonants, which have thus no opportunity of asserting themselves, and the result is that the hearers have but a vague conception of the words that are uttered. Audibility is not dependent on volume of sound. Many speakers are unintelligible because of loudness of voice. A peculiar effect is often produced after the first few minutes by the very loud speaker, especially if in a monotone. The auditors are delighted to hear his strong, melodious voice, but after listening for a while they become conscious of difficulty, and before he closes have lost interest. The impact upon the tympanum and upon the finer fibers within has dulled sensibility. Some speakers employ but two tones, one a low pitch, and the other a piercing shriek, which they alternate with uniformity now and again, with no regard of sense or length of the intervals. Others allow the voice to fall at the end of sentences, and occasionally on emphatic words. Those who attain high success as speakers must be heard agreeably, and, if possible, their voices should be musical. Under no circumstances should the speaker be content to allow his voice to remain rough, harsh, or grating. Many extemporizers have but one style of delivery. Their tones are the same whether they deliver a business statement, a presentation speech, a congratulatory address at a golden wedding, a witty after-dinner response, or a patriotic oration.

Suggestions for Speakers.—No pains, nor toil, nor time should be spared in careful preparation, in making descriptions of cases graphic and forcible, statements lucid, appeals pathetic, in filling the subject with what will both strike and stick. It is necessary that a doctor shall have a clear conception of his subject in order to instruct and convince. Vivid conception generates power. Let the divisions of subjects be clear and logical. These should be simple, natural, progressive, and thoroughly mastered. If possible, the physician should have facts, points, arguments and illustrations at his tongue's end. There is power in illustration. Let the illustrations be from recent occurrences.

Delivery.—The first duty of a physician in addressing an audience is to make himself heard. If he speaks very rapidly, his hearers will miss words here and there, and he fails to produce the effect intended. He should be full of his subject and im[illegible] ith its [illegible]tance. He should speak deli[illegible] tinctly, and in a natural voice. [illegible] thoughts with clearness and [illegible] should be a sharp, clear summary of established propositions, forced home, perhaps, by an impressive illustration. One of the cardinal virtues of good speaking, therefore, is distinctness of utterance. A speaker may be slow and deliberate, may express himself in exceptional English, and be in all other respects easy to report; but if he has not acquired the art of making himself heard, much of what he says loses its effect.

The real secret of effective delivery lies in the ability of a speaker to impress himself with his subject. He for the time becomes the standard by which all thought and feeling and sentiment of a whole assembly are measured; nor can he hope to produce in his hearers an interest greater than his own. A good speaker, as his mind becomes inflamed with unwonted activity, rises to a plane of thought and feeling of which he himself is altogether incapable in his calmer moments. His conception is sharpened and his thoughts come with a clearness and precision that leave no time for hesitation. The mind, as it were, becomes intoxicated with its own ideas. The perception of the hearer is correspondingly quickened, and the audience, catching the inspiration of the speaker, unconsciously rises with him if animated by the same spirit. Speaker and hearer have become thoroughly *en rapport,* and it may be truly said of a great assembly, "a thousand souls with but a single thought, a thousand hearts that beat as one." Ability to become deeply impressed with the subject under consideration, the power to rise to a sublime conception of it in delivery, and the faculty in a speaker of transmitting his own inspiration to his hearers is the real basis of good, effective speaking. While all physicians can never hope to attain a high type of oratory, still some may be greatly benefited by a better understanding of the principles that underlie good speaking.

One of the facts disclosed by reporting physicians for the last sixteen years is the marked tendency toward greater simplicity of expression. Involved sentences and the use of big words to say little things are not tolerated as they once were. Conciseness and condensation, as elements of style, have largely taken the place of classicism. It is not so much stateliness as incisiveness that is sought. The axiom of the modern speaker appears to be that to talk effectively one must speak tersely. The most pleasing and impressive speakers are those who understand word-history best, and who are most skilled in the nicer refinements of our vocabulary. To feel the force of all there is in their speeches we must partake of the same kind of knowledge, and hence derive the same discriminating instinct.

Diffuseness.—A common error among young physicians, in discussing papers read before medical societies, is a tendency to diffuseness, which may be defined as a copious use of words so arranged as to create the suspicion that a thought is somewhere concealed among them. The youthful physician, and, we regret to say, some of the older members of the profession, in debate, feel it necessary to describe ordinary things in an extraordinary way, and strive to dignify commonplace thoughts by clothing them in fulsome rhetoric. The result is a painful incongruity between the thoughts and their apparel. For instance, a young physician instead of saying that a man was thrown sideways from his carriage, breaking his leg and putting his ankle out of joint, said that "the patient was projected transversely from his vehicle, fracturing the tibia and fibula and luxating the tibiotarsal articulation."[1] Again, another speaker, instead of saying that he had found a large cancer of the liver at a post-mortem examination, said that he had found "a colossal carcinomatous degeneration of the hepatic mechanism." The effect of the use of such large words is usually heightened by an overwrought, stilted delivery as unnatural as it is unnecessary. These faults can be corrected by time and experience. Simplicity is really the thing to be sought. In this connection we are reminded of an excellent story which is told of Dr. Skinner,[2] an eminent theologian. He was unable to use simple words in either preaching or lecturing. One Sunday he was asked to address the Sunday-School class, and consented to do so. He began his address in this wise: "The Westminster Catechism is an admirable syllabus of Christian doctrine." As soon as he had uttered those words, the superintendent intimated that the children could not understand him, whereupon he said: "Your superintendent informs me that you do not understand what I say. Let me explain: Syllabus, my dear children, is synonymous with synopsis."

Rate of Speaking.—The average rate of public speaking is put down in most shorthand text-books at 120 words per minute. This average is too high for the medical profession, whose members deal largely in technical terms. The rate of speaking of some of the greatest orators varies from 100 to 130 words per minute. It is said that John Bright and Gladstone, in beginning their speeches, rarely exceeded 85 words per minute, but as soon as they became interested and deeply absorbed in the subject in hand, their rate of speaking ranged all the way from 85 to 130 words per minute, and during flights of oratory they would reach 150 words per minute for a short time. Bryan, the Democratic candidate for President, in delivering an address to a large audience in this city not long since, spoke so slowly that his speech was taken verbatim by an expert typewriter operator. He did not exceed 82 words per minute. The late Colonel Ingersoll, one of America's greatest orators, spoke at the rate of 130 words per minute, and could keep it up for hours without, apparently, any strain on his voice, which was that of a sustained, animated conversational tone. My estimate of his rate of speaking is based on a lecture which I reported for a local newspaper several years ago. At that time the Colonel spoke for two hours and forty minutes. One of the most rapid speakers in the medical profession I have ever reported was the late Charles T. Parkes, professor of surgery in Rush Medical College. I reported twelve didactic lectures for him on "Fractures and Dislocations." These lectures were delivered without notes. His average rate, during a fifty-minute lecture, was 175 words per minute. Parkes belonged to the jerky, spasmodic type of speakers. Words fell from his lips in volleys, and each volley was usually preceded by a short grunt.

I append a partial tabulated statement, giving the rates of speaking of those physicians whose discussions and lectures I have repeatedly reported from time to time:

Speaker.	Rate of speaking.
Joseph M. Mathews	110 words per minute.
George Ben Johnston.	110 " " "
William E. Quine	115-130 " " "
D. R. Brower	115 " " "
F. W. McRae	115 " " "
Robert T. Morris	120 " " "
W. E. B. Davis	120 " " "

---

[1] Edmund Andrews: Introductory Address, JOURNAL, Vol. xxv, Nov. 2, 1895.

[2] James M. Buckley: Extemporaneous Oratory.

Speaker.	Rate of Speaking.
W. W. Keen	125 words per minute.
Rudolph Matas	130 „ „ „
Charles A. L. Reed	130 „ „ „
Arthur D. Bevan	130 „ „ „
T. J. Happel	135 „ „ „
D. A. K. Steele	135 „ „ „
Richard Douglas	140 „ „ „
Nicholas Senn	140 „ „ „
J. Henry Carstens	140 „ „ „
Howard A. Kelly	140 „ „ „
Henry M. Lyman	145 „ „ „
James F. Baldwin	150 „ „ „
J. B. Murphy	150 „ „ „
A. M. Cartledge	160 „ „ „

Only a rough estimate can be given of the speed of any speaker, for the reason that his rate of utterance varies with the nature of the subject, his familiarity with it, etc. Senn, Carstens, Quine, Bevan, Kelly, Keen, and many others vary their rate of speaking very materially, particularly when familiar with the subject under discussion, and pressed for time.

Logorrhea.—Washington Irving says: "Redundancy of language is never found with deep reflection. Verbiage may indicate observation, but not thinking. He who thinks much says but little in proportion to his thoughts. He selects that language which will convey his ideas in the most explicit and direct manner. He tries to compress as much thought as possible into a few words. On the contrary, the man who talks everlastingly and promiscuously, who seems to have an exhaustless magazine of sound, crowds so many words into his thoughts that he always obscures, and very frequently conceals, them.

The free and unrestrained use of words leads to volubility, profuseness and increased rapidity of speech, and increased rapidity of speach leads to inaccuracy of expression, which sometimes renders the efforts of a speaker worthless and unavailing. The reporter in such cases is the protective shield of the speaker, and everything spoken by such men should go through a kind of reportorial refinery before it is published. A lawyer, for instance, has a good case, and has it well prepared. On the trial he examines his witnesses with a string of questions so involved, complicated and illy expressed, and the ideas sought to be conveyed to the jury are so deeply buried and hidden beneath a mountain of needless words, as to bewilder and confuse, and then he wonders why he lost his case. No one is better situated to note the disastrous effects of the inapt and ineffective use of words than the reporter. Pope expressed the matter in a few words when he said:

> Words are like leaves, and where they most abound,
> Much fruit of sense beneath is rarely found.

Long sentences are fatal to clearness and force, however well constructed they may be, and should be studiously avoided.

Precision.—Precision is also of the utmost importance, and can only be attained by a nice discrimination in the use of words. Such words should be chosen as shall express the exact shade and quality of meaning required by the context.

Ambiguity.—Ambiguity is another foe to clearness. The arrangement, as well as the language, should be such that we not only may, but that we *must*, be understood. The first principle of strong oral composition demands the employment of as few words as will clearly express the thought. This rule, carefully followed, will eliminate redundancy, circumlocution, and all kindred evils that weaken the style of many otherwise good speakers.

Analysis and Plan of Delivery.—Much depends upon the analysis of the subject and the plan of delivery. Many physicians, gifted with a certain eloquence of voice and manner, have a faculty of entertaining their auditors with a sort of medley in which neither plan nor purpose is apparent. They may discontinue speaking at any point, and no one would feel its incompleteness, or be in anywise disconcerted. After hearing such a speaker one is conscious of having remembered nothing in particular, and carries away no impression save that of having been pleased. With other physicians the marshaling of sentences and propositions is apparent from the beginning, and the march to a conclusion as concerted and orderly as the advancing columns of an army.

As one of the greatest elements of success in good speaking, may be mentioned carefull and thorough preparation, and a clear idea of the subject to be discussed. No physician can expect to sway his hearers unless he is a perfect master of the subject in hand. In growing earnest, impressive, or in reaching for a climax, it is not necessary for him to rant or roar. Much energy is wasted by professors in lecturing to medical students in this way that might be advantageously saved. To be energetic and eloquent, it is not necessary to declaim boisterously.

Many physicians begin speaking before they know precisely what they mean to say. Others perceive things clearly, and those having this power, though of slow mind, may speak more coherently and fluently than those who, without clearness of thought, possess greater animation. The unlearned and untrained may think as clearly and deeply, within the circle of their powers, as the accomplished; and frequently, on account of freedom from abstraction or distraction produced by a multiplicity of ideas, they penetrate to the heart of a subject, and reason more shrewdly and correctly than do the educated. This is particularly true of country physicians. In discussing ordinary medical and surgical topics, they frequently surpass the average college professor in clearness of thought, command of language, ease and vigor of expression.

Paucity of Language.—Paucity of language is a common defect of extemporaneous speech, and a stenographic report of several speeches delivered by the same person will exhibit this defect in a mortifying manner, when, in response to the requests of those who have heard them, the orator attempts to collect them for publication. It is then difficult for him to believe his vocabulary so meager, the forms of his sentences so similar, that so many phrases often recur, and that there seems to be an irresistible tendency to use the same words, even when other words express the shade of meaning which he endeavors to communicate with greater accuracy than the familiar terms which go so trippingly over his lips. Excess of repetition in the same speech is a serious evil and sufficient to account for the lack of success which attends many who are nobly endowed in voice and figure, and not destitute of a rich and expressive vocabulary.

Oft-Recurring Phrases.—Scattered throughout a reporter's note-book will be found such oft-recurring phrases as, "Permit me to say": "I am [illegible] to declare"; "I am bound to maintain" [illegible] and nobody can deny it"; "I don't [illegible]-tion to this I mean"; "What I to me"; "It appears to me"; "One word more and I have done."

These are a few of many examples of such oft-repeated expressions. The legal and ministerial professions are as guilty as the medical profession in this regard. An old physician once said to me that whenever a man used such phrases during an impromptu speech he was "simply sparring for thought, and as filling material they came in nicely, but should never appear in print."

Reporters Sometimes Unjustly Assailed for Inaccurate Reports.—Occasionally a physician will severely and unjustly denounce a report of a lecture or discussion as inaccurate without stopping to think of the causes which lead to it. Inaccurate reports may be largely attributed to:

1. Noises in the room or hall in which the reporter is taking notes.
2. Indistinct utterance or imperfect enunciation on the part of the speaker himself.
3. A conversation being carried on near the reporter's table between two members, while some one is addressing the society.
4. The speaker dropping his voice at the end of sentences, the final words being inaudible or doubtfully heard.
5. Extreme hoarseness on part of the speaker.
6. Too great a distance between reporter and speaker, particularly when the latter has a voice of feeble carrying power.
7. Stifling of the speaker's voice by the noise of a car heard through open windows.
8. Sneezing or coughing during debate.
9. The slamming of doors.
10. Noises from the street during hot weather, when the windows of the hall in which a meeting is being held are open.
11. Clearing of the throat on the part of some person while another is speaking.
12. Partial, but temporary, deafness on part of the reporter induced by a cold.
13. A change in the physical and mental condition of the reporter, induced by a long siege of note-taking, the mind acting sluggishly and the muscles protestingly.
14. The speaker turning his back toward the reporter.

Physicians and Lawyers Compared.—The art of speaking well is not confined to statesmen, jurists, and clergymen. The medical profession, like the ministerial and legal professions, has orators within its ranks. The experienced doctor strives to use the simplest and most expressive words. According to Bryce, rhetorical excellence consists in: "1. The power of finding good ideas and weaving effective arguments. 2. Skill and taste in the choice of appropriate words. 3. Readiness in producing appropriate ideas and words at short notice. 4. Weight, animation, and grace in delivery."

I have had the pleasure of reporting the utterances of several eminent lawyers from time to time, and, to speak candidly, I must confess that they were not the superiors in any sense of many of the physicians whose impromptu speeches I have reported. I shall mention three striking examples of the extemporaneous type of speakers in the medical profession, and later submit a classification.

Dr. Nicholas Senn is a fluent, forcible and impressive speaker. He has an excellent command of language. There is a richness in his diction, a copiousness, ease, and variety in his expression which are rarely surpassed by the best extemporaneous speakers. The arrangement of his sentences in debate seems never to have been studied, yet every word falls into its proper place. He displays his ability as a debater to best advantage when under a heavy fire. On one occasion, during a spirited discussion, which was called forth by a paper which he had read, he sat with a smile on his face, listening attentively to everything that was being said, while several prominent surgeons were severely criticising the operation he had proposed; but when the time came to reply to the various criticisms that had been showered upon him, in an unassuming way he scored his opponents one after the other in a dignified but merciless manner, and showed with great clearness of statement how feeble and groundless were some of the views that had been advanced.

Dr. Charles A. L. Reed, of Cincinnati, Ohio, the President of the American Medical Association, is a splendid example of the extemporaneous speaker. As a debater he is well equipped. He is known for his elegant diction, his scholarly references, and the ornateness of his phraseology. His well-rounded sentences are marvels of construction. No matter how sudden the summons, or what the subject, a speech from him is always interesting. His rhetoric is faultless; his delivery graceful and easy.

Dr. Joseph M. Mathews, of Louisville, Ky., is an easy, graceful, fascinating, polished speaker. His style is notable for its simplicity. He can adorn any subject. Those who have had the pleasure of hearing his celebrated lecture on "The Lights and Shadows of a Doctor's Life," will recall with what eloquence, pathos, and flashes of humor he treated this subject. One minute his hearers were on the verge of shedding tears, the next convulsed with laughter, so easily and tenderly did he touch the chords of the human heart.

As examples of good extemporaneous speakers in the medical profession, men who make themselves heard, who know and feel what they say, and who can command the undivided attention of any audience, I may mention Drs. W. W. Keen, William E. Quine. G. Frank Lydston, Harold N. Moyer, J. Henry Carstens, James B. Herrick, Weller Van Hook, Arthur D. Bevan, D. R. Brower, A. M. Cartledge, J. B. Murphy, Henry M. Lyman, William A. Evans, F. W. McRae, L. S. McMurtry, Dudley S. Reynolds, W. E. B. Davis, Rudolph Matas, T. J. Happel, Richard Douglas, George Ben Johnston, Lawson Tait, Joseph Eastman, Sir Thomas Grainger Stewart, William Macewen, and a host of others did space permit.

Classification of Speakers.—The reporter is constantly listening to speakers, good, bad and indifferent, and soon comes to recognize the qualities that cause a man to rank in one or other of those classes. He is essentially a speech-taster. It is a significant fact that speeches delivered in a quiet, deliberate way, when the speaker has a good command of sound English, and has something to say that is worth hearing, nearly always give the reader the idea that they must have been delivered with great fluency. On the other hand, the really fluent speeches, those with long sentences, each sentence containing several clauses, and sometimes one or more parentheses, give the reader of them the idea of hesitation and lack of preparation. A study of the different styles of doctors as speakers encountered during an extensive and varied reportorial experience is an education in itself, and by virtue of his vocation the reporter is compelled to study them. As there is no one more competent to criticise physicians as speakers than the man on whom devolves the duty of reporting them, I have made an attempt to classify the speakers whose utterances I have reported from time to time in medical societies. We have the following classes:

1. The moderately slow speaker.
2. The exuberant and tempestuous speaker.
3. The musical, flowery speaker.
4. The loud, husky speaker, whose voice is somewhat indistinct.
5. The grandiloquent speaker.
6. The rapid and spasmodic speaker.
7. The excessively rapid speaker.
8. The rapid, involved and indistinct speaker.
9. The one who hurls disconnected sentences at the reporter.
10. The clear, distinct, unassuming speaker, who talks with absolute precision, with perfect grammar. He is a *rara avis*.
11. The physician who commences his speech in a deliberate, measured, distinct, far-reaching tone of voice, and who, when he becomes influenced by the magnetism of his audience and their rapt attention, gives vent to rare flights of oratory.
12. The irrepressible speaker, who does not know enough to sit down while he is down, but who monopolizes the precious time of an important convention in saying practically nothing; still, his remarks are reported, transcribed, and then, perhaps, liberally blue-penciled, or consigned by the secretary of the association or editor to the waste-basket.
13. The one who jumbles up his nominative, his accusative and his verb with such picturesque incoherence that it is almost impossible to make head or tail of what he means.
14. The physician who threads his way through a long and apparently intricate sentence, never losing the connection of the parts, and coming out at the end with absolute precision.
15. The man who does not realize that his first duty is to make himself heard.
16. The physician who never completes his sentences, but is utterly oblivious of that fact when he criticizes the report of his speech.
17. The physician who misquotes, and then blames the reporter if he has not supplied the correct quotation.
18. The foreigner, who imagines that he speaks like a native.
19. The speaker who drops his voice at the end of sentences.
20. The low, mumbling, conversational style of speaker, who indulges in a free and rapid flow of words which taxes the reporter's skill and dexterity.
21. The physician who is extremely subtle in the use of words and phrases. The shades of meaning are so delicate by the judicious selection of them that the reporter must retain the original force and color of each sentence.
22. The physician who habitually clothes his hazy ideas in loose, disjointed talk, which, if transcribed as uttered, would mar, if not ruin, his reputation.
23. The one with a slow and fatiguing mode of utterance, whose sentences are diffuse, intricate and deficient both in eloquence and precision.
24. The physician who is clear, forcible, persuasive, with an eloquence natural and direct. (This type of speaker usually spends much time in meditation and in the composition of his speeches.)
25. The physician whose speeches are notable for their subtlety of discrimination and depth of learning.
26. The physician who evolves original thoughts and whose voice and gesture emphasize living truths.
27. The eccentric physician who stifles and distorts natural eloquence. His introductory is long; divisions and subdivisions of speech are perhaps illustrated by a pointless story.
28. The physician who carefuly selects his words and utters sentences that are models of syntax.
29. The man whose style is natural, easy and varied, with short clauses expressing vivid ideas.
30. The tautological physician.
31. The vivid, brilliant speaker who pours out a torrent of words, dexterously handled, and whose remarks are full of sudden turns and surprises, but are illumined by ingenious reasonings.
32. The man with a strange and unfamiliar style, whose sentences are portentously long.
33. The rapid and monotonous speaker who becomes tangled in his own sentences, and mispronounces words.
34. The physician who is known for his elegant diction, his scholarly references, and the ornateness of his phraseology.
35. The physician who stutters, speaks indistinctly, and yet is extremely technical.
36. The pompous speaker.
37. The physician who begins a sentence, but is not satisfied with its construction; he therefore draws up, makes a plunge in another direction, wanders about in a maze, and finally lands in a region of impenetrable obscurity.
38. The physician who is afflicted with that terrible malady—*cacoethes loquendi.*

The two qualities in a speaker which most delight reporter and hearers are lucidity of thought and distinct utterance. Purity of tone, clearness of enunciation, and deliberate utterance are what make public speakers heard and interesting.

THE IDENTIFICATION OF DEXTROSE IN HUMAN URINE.*

HEINRICH STERN, Ph.D., M.D.

Professor of the Diseases of Metabolism, College of Physicians and Surgeons, St. Louis; Visiting Physician, New York Red Cross Hospital; Attending Physician, St. Elizabeth's Hospital; Member American Medical Association; Member American Chemical Society; Fellow New York State Medical Association, etc.

NEW YORK CITY.

(Concluded from page 683.)

Repeated filtration of the urine through animal charcoal causes retention by the latter of uric acid, urates, coloring substances, some albumin, but also of certain amounts of dextrose. Powdered animal charcoal, freed from impurities as well as possible by washing and by extraction with hydrogen chlorid, is put to the height of 3 cm. into a filter measuring 5 to 6 cm. in diameter. Twenty to 40 cm. of urine are repeatedly filtered through this layer, until the filtrate is rendered perfectly colorless. As particles of dextrose are retained by the charcoal, this should be washed three times with distilled water, and each of the three washings is examined separately. Fehling's test is then applied to the filtered urine and the washings. The advantage obtained by this procedure is obvious, still decolorized urine may yet possess reducing factors.[9] It was found that, notwithstanding the absence of dextrose, the test occasionally reacted positively, and that, on the other hand, dextrose, which was positively recognized by other processes, could not be detected when repeated filtration through animal charcoal had taken place. The modification of Worm-Müller is a decided improvement on the older copper tests. It does not, however, eliminate the afore-mentioned disturbing factors, but their occurrence is not so formidable. This method depends on the fact that at a temperature below 70 C., reducing substances other than dextrose either do not react at all with the Fehling's solution, or only to a diminished degree. The reagent is prepared by dissolving 10 grams of potassium and sodium tartrate in a 4 per cent. solution of sodium hydroxid, or in a 5.6 per cent. solution of potassium hydroxid; 2.5 cm. of this solution, together with 1 c.c. of a 2.5 per cent. solution of copper sulphate, are heated not quite to the boiling-point. Five c.c. of the suspected, previously filtered, albumin-free rendered urine is heated to the same degree and at the same time. Twenty to twenty-five seconds are allowed to elapse for cooling, after which the urine in small portions is carefully put into the test-tube containing the reagent. The bluish-green color of the latter rapidly disappears if glucose is present; yellow-red cuprous oxid is separated, and together with xanthin bases and uric acid, is kept suspended in the mixture for a long time. The cuprous oxid is readily recognized by holding the well-illuminated tube against a dark background. If no cuprous oxid is separated within five or ten minutes the test should be repeated with 1.5 c.c. of the solution of copper sulphate; then, if still negative, 0.5 c.c. more of the copper solution—that is, 2 c.c.—are used. The testing, if the cuprous oxid has not separated in the meantime, is continued, and for each successive application 0.5 c.c. more of the copper solution is added, until 4.5 c.c. are utilized for one test.

---

*Read at the Sixteenth Annual Meeting of the Fifth District Branch of the New York State Medical Association, held in Brooklyn, May 22, 1900.

Phosphates, the presence of which may give rise to wrong interpretations, unlike cuprous oxid, are thrown down in short order. All the other copper tests, Salkowski's, Fehling's, Haines', Pavy's and Elliott's, are nothing more than modifications of the original copper test—Trommer's; they are affected by the very same disturbing factors, and are consequently liable to kindred erroneous interpretations. Haines' and Elliott's methods, however, possess the advantage over the other modifications that only very small amounts of urine are needed. Eight drops of urine, and never more, are utilized in performing one of these tests, which, therefore, lack somewhat in sensitiveness. On the other hand, by the utilization of only small amounts of urine, a possible pseudo-reduction by a non-saccharin reducing agent is excluded to some extent, as but eight drops of urine, even if in a somewhat higher degree of concentration, do not contain sufficient quantities of reducing substances other than dextrose to effect a pseudo-reduction.

THE PHENYLHYDRAZIN TEST.

This test depends upon the quality characteristic of phenylhydrazin to form compounds—osazones—with different varieties of sugar. The union with grape-sugar—phenylglucosazone ($C_{18}H_{22}N_4O_4$)—occurs in yellow needle-shaped crystals, which must be detected by the aid of the microscope. Jaksch, Jolles, Ultzmann and Havelburg devised different methods for the execution of these tests. Havelburg's modification, which is a much more convenient process than the original mode of application, is yet not mentioned by the standard works. In my "Recent Studies in Urinology," N. Y., 1898, I gave the following directions for the application of Havelburg's modification: "Put in a test-tube 1.2 grams phenylhydrazin hydrochlorate and 1.8 grams sodium acetate; add 10 c.c. of distilled warm water. Warm a little and add 10 c.c. of the suspected, previously filtered, urine and from eight to fifteen drops of chloroform. Shake well and set aside. The chloroform will soon fall to the bottom, and, if sugar is present in the urine, a fluid layer will be produced above it in which the phenylglucosazone crystals are contained. Remove part of the fluid layer by means of a pipette and examine it on a slide under the microscope for crystals of phenylglucosazone."

Tolles recommends the following modification: To 10 c.c. of albumin-freed urine of normal consistency (of concentrated urine 5 c.c. are utilized and diluted with an equal volume of water), 0.5 grams phenylhydrazin hydrochlorate and 1 gram of sodium acetate are added. The mixture, while warmed for an hour or longer on a water bath, is repeatedly agitated; after cooling, a small amount of the yellowish deposit is examined under the microscope for phenylglucosazone.

Notes.—The phenylhydrazin test, formerly considered the most sensitive and trustworthy method for the detection of urinary glucose, in point of accuracy, has been decidedly overrated, for normal urine treated with phenylhydrazin may occasionally furnish crystals, which in appearance do not at all differ from those of phenylglucosazone. A certain individual's urine, which I had occasion to examine more than thirty times, and which in every instance proved to be absolutely normal, when subjected to the phenylhydrazin test, always furnished crystals seemingly identical with those of phenylglucosazone. Glucose, however, and glycuronic acid combinations were positively not contained in the urine. On the other hand, the phenylhydrazin test may at times not respond when the presence of sugar has been proved beyond a doubt by other methods. Shape and arrangement of the crystals are apparently of no significance regarding the nature of the osazone constituents. In order to render the phenylhydrazin test conclusive, the true nature of the crystals has to be ascertained. This is accomplished by a determination of their melting-point. Other urinary constituents besides glucose combine with phenylhydrazin to form either insoluble, or, with difficulty, soluble, compounds. With the pentoses, pentosazone; with acetone, acetonhydrazon, $(CH_3)_2C{:}N.NH.C_6H_5$, are furnished. Glycuronic acid, which never occurs in the free state in the urine, combines with phenylhydrazin; so does oxalic acid; carbamid in concentrated urine of the dog also enters into a union with phenylhydrazin.

Disturbing factors and sources of error.—Glycuronic acid combinations, fructose, pentoses. While in all probability glycuronic acid as such is never found united with the phenyl salt in human urine, some of its glycosidal combinations undoubtedly form osazones. In appearance and solubility the phenylosazone crystals of glycuronic acid or its combinations are analogous to the crystals of phenylglucosazone. Glycuronic-acid phenylosazone is distinguished from phenylglucosazone by its melting-point. The former melts at 114 to 115

---

[9] Robert Saundby (Brit. Med. Jour., April 14, 1900) is still of the opinion that all of the reducing agents except sugar are removed by this process. Decolorization of normal urines, however, is by no means identical with the separation of all possible reducing substances.

C., phenylglucosazone at 204 to 205 C. and in its impure state at 173 to 194 C. The osazones of the various sugars possess specific characteristics as to form, melting-point, solubility and optical behavior. The osazone of fructose, however, is identical with glucosazone. Fructosazone forms somewhat more rapidly than glucosazone, which fact seems to be due to the quicker decomposition of levulose. Pentosazone differs from glucosazone in its melting-point, which is at 159 to 160 C. Lactosazone melts at 200 C.

MOORE-HELLER'S TEST.

Moore-Heller's test depends upon the decomposition which dextrose undergoes when it is boiled with sodium or potassium hydroxid. To the urine contained in a test-tube one-third of its volume of sodium or potassium hydroxid solution is added, after which the mixture is boiled. If sugar is contained in the urine a brownish coloration will presently ensue. The change in color is more readily noticed if only the surface part of the mixture is heated. The brown color becomes more intense if the boiling is continued for one or two minutes, provided the percentage of glucose is above 0.5. The alteration in color is due to the production of glucic and melassic acids. On addition of a little nitric acid the brown color disappears, and the odor of caramel or of formic acid is evolved.

Notes.—The precipitate separating from the urine after the latter has been rendered alkaline, and which increases after the mixture has been subjected to heat, is of no moment, as far as the reaction is concerned, as it is composed of earthy phosphates; it is better to separate them by filtration before the mixture is boiled. As normal urine, when subjected to heat, will also assume a slight degree of brownness, the darkening must be well pronounced if sugar is contained in the examined specimen. Urines containing carbonate of ammonium must be repeatedly boiled with an excess of the alkaline hydrate before results can be obtained.

Disturbing factors and sources of error.—Impure alkaline solutions, mucin, proteids, biliary pigments, alkaptonic acids. The reagents should be chemically pure and should be kept in green-glass bottles. Urine rich in mucin, when boiled with NaOH or KOH, darkens to about the same degree as does a urine containing a small percentage of glucose. Mucin and proteids are previously separated by boiling and filtering. Biliary pigments occurring in urine call forth a brown coloration of the latter on the addition of NaOH and KOH without the employment of heat. They are removable to some extent by filtering the urine through animal charcoal. Urine exposed to the air and containing alkaptonic acids, when treated with NaOH or KOH, assumes a dark-brown color. However, I have noticed the gradual appearance of the dark coloration in urines containing alkaptonic acids which were simply left exposed to the air when no caustic alkalies had previously been added.

PENZOLDT-RUBNER TEST.

Equal parts of urine and of a concentrated solution of normal plumbic acetate, $Pb(C_2H_3O_2)_2 + 3H_2O$, are added together, and the resulting precipitate is filtered off. To the filtrate, ammonia is added, drop by drop, until a heavy white deposit of lead saccharate is formed. On the application of heat the precipitate turns to a flesh color or to a darker shade of red. If the heat applied does not exceed 80 C., the red coloration is indicative of glucose only, and not of lactose.

Notes.—Urines of a higher specific gravity than 1010 should be diluted before the test is applied, which is spoiled by an excess of ammonia. Voit and Moritz devised modifications of this test, which, however, do not seem to possess any special advantages. I have used the following modifications for the past ten years with uniformly good results. I cite from my "Recent Studies in Urinology," page 33: "Take from 1 to 5 c.c. of urine and put to it an equal amount of ammonia hydroxid; add about 5 drops of a strong solution of lead acetate. A whitish, flocculent sediment composed of sulphate, phosphate and chlorid of lead and hydrated lead oxid, $PbO(OH)_2$ appears immediately. Heat gently a part of the sediment over an alcohol lamp until two or three bubbles ascend. If glucose is present there will appear in the heated region of the sediment a well-defined, distinct pink spot, the intensity of which is dependent on the amount of dextrose present." I have found that when glucose occurred in as small an amount as 0.1 per cent., the pinkish spot was plainly noticeable. If glucose is present in smaller quantities than 0.1 per cent., the spot on the heated portion of the sediment will appear yellowish. This spot, on account of the coloration of the urine, is not always noticeable. It is best to use test-tubes of the smallest caliber only, when applying this test, and I advise the use of new tubes—previously well cleaned with distilled water—if urine containing but small amounts of dextrose is to be scrutinized. Albumin, uric acid, creatinin, pigments and the alkaptonic acids do not influence the reaction.

Disturbing factors and sources of error.—When the test is properly executed apparently no source of error arises. It is possible, however, that certain glycuronic-acid combinations may call forth a similar circumscribed coloration in the precipitate. Indoxyl-sulphonic acid is present in the precipitate, and may, under certain conditions, give rise to a discoloration.

THE METHYLENE BLUE TEST.

Frœlich[10] employs the following procedure (Stern, Recent Studies in Urinology): "To 10 c.c. of the urine to be examined add about 5 c.c. of a concentrated solution of sugar of lead (neutral plumbic acetate), shake well and add 5 c.c. of a concentrated solution of lead acetate (basic lead acetate). Put on a dry, open filter. The filtrate will be almost always of a water-like, colorless, sometimes slightly yellowish, appearance. Place into a test-tube some of the filtrate; into another test-tube put an equal volume of a concentrated aqueous solution of methylene blue (1 gram of the purest methylene blue in 300 parts of water). Render the methylene-blue solution strongly alkaline by the addition of potassium hydrate (to 5 c.c. of the methylene-blue solution add about 1 c.c. of a 10 per cent. solution of KOH). Warm the alkaline solution of methylene blue over an alcohol lamp and add to it the filtrate contained in the other test-tube and heat again to the boiling-point. If dextrose be contained in the urine, the bluish-black mixture will turn lighter, become whitish, and finally clear and transparent, with a faint tinge of yellow. The reaction is not disturbed by the excess of lead, which is thrown down as a white deposit. Frœlich employed in every instance 5 c.c. of the filtrate, and 5 c.c. of the solution of methylene blue, with the addition of 1 c.c. of KOH solution to the latter; however, a few drops of the filtrates of urines abundant with glucose are sufficient to decolorize 5 c.c. of the solution of methylene blue. When the percentage of dextrose is small, less than 2 per cent. the equal volume of the filtrate must be added. The discoloration of the mixture occurs most always within twenty to twenty-five seconds after the removal of the tube from the lamp. The tube should be kept as quiet as possible, as even a slight shaking may result in a bluish coloration of the upper layers by the oxygen of the atmosphere. The decolorized mixture will again turn bluish on shaking, which will, however, disappear upon standing. The limit of sensitiveness of this test Frœlich maintains to be between 0.4 and 0.5 per cent. glucose. With a percentage of less than 1 per cent., the reaction will occur somewhat slower. Every urine may decolorize methylene blue. Urea, uric acid, chlorid of sodium and albumin do not reduce methylene blue in an alkaline solution. Creatin and creatinin, according to Frœlich, will not reduce the same; neither will the biliary pigments, which, however, will turn the solution to a green color. Those urinary constituents, which, besides glucose, may decolorize methylene blue—pigments and glycuronic acid and its compounds—are thrown down by the lead solutions, and, therefore, do not disturb the test.

---

[10] Centralblatt f. innere Med., Jan. 20, 1899.

Disturbing factors and sources of error.—Levulose, creatinin may reduce methylene blue in an alkaline solution, also creatin on boiling for a longer period. Normal urine, as I have repeatedly noticed, will also cause a reduction of the reagent. Normal urine possesses the reducing qualities of a 0.1 per cent. solution of glucose.

THE PICRIC ACID TEST.

A solution of grape-sugar on being heated with an equal bulk of saturated watery solution of picric acid and some potassium or sodium hydroxid will assume a beautiful dark-cherry coloration. The alteration in color is caused by the production of picramic acid. The presence of albumin does not interfere with this test.

Disturbing factors and sources of error.—Uric acid, creatin, creatinin, acetone, pigments, glycuronic acid combinations. Urine free from glucose to which this process has been applied undergoes a similar, but slighter, coloration. The power of reducing picric acid is possessed by normal urine to the same degree as by a 0.1 per cent. solution of dextrose.

THE TEST WITH SODIUM-SULPHO-INDIGOTATE.

$C_{16}H_8N_2O_2(SO_3Na)_2$.

Take a solution of indigotin—disulphonic acid—$C_{16}H_8(HSO_3)_2N_2O_2$—saturated with sodium carbonate, on being boiled with a solution of dextrose turns green, purple, red and yellow. The mixture resumes its original blue coloration on shaking the still warm yellow solution, when the order of appearance of the colors is reversed—yellow, red, purple, green and blue. Care should be exercised in avoiding agitation of the tube during heating.

Disturbing factors and sources of error.—Pepton, glycuronic acid compounds, inosit, lactose, gallic and tannic acids, salicylic acid, salol, salicylates.

THE TEST WITH ORTHONITROPHENYLPROPIOLIC ACID

$C_6H_4(NO_2)C{:}C.COOH$

G. Hoppe-Seyler's test: Orthonitrophenylpropiolic acid, on being boiled with glucose and sodium carbonate, furnishes indigo; excess of sugar causes a reduction of indigo-blue to indigogen (indigo-white) $C_{16}H_{12}N_2O_2$. The test is applied as follows: To 5 c.c. of the reagent—0.5 per cent. of the solution of orthonitrophenylpropiolic acid in caustic soda and water—10 drops of the suspected urine are added, after which the mixture is boiled from fifteen to thirty seconds. If the solution turns dark blue—indigo reducing agents—at least 0.5 per cent. sugar are present.

Notes.—The test should be applied only with an excess of the reagent. Normal urine causes a green coloration after at least 1 c.c. has been added. A pronounced blue coloration with normal urine occurs but rarely. Albumin does not interfere with the test.

Disturbing factors and sources of error.—Lactose, indoxyl, and indoxylic acid cause the same reaction; creatin in excess calls forth a green coloration.

THE TEST WITH PARADIAZOBENZOLSULPHONIC ACID.

Penzoldt's test: If to a solution of sugar rendered alkaline with fixed alkali, paradiazobenzolsulphonic acid —$C_6H_4N_2SO_3$—is added, a red coloration turning gradually to violet will ensue within ten or fifteen minutes. When properly diluted the mixture may then show an absorption band between D and F and another one at G.

Notes.—Penzoldt uses the reagent in a dilution of 1 to 60 parts of water. The reagent should be kept under chloroform to prevent its explosion.

Disturbing factors and sources of error.—Albumins react with the reagent; like sugar; acetone; phenol and brenzcatechin.

THE FURFUROL TESTS.

The decomposition of the carbohydrates by sulphuric acid occurs under the production of furfurol. This is detected, even if it is present but in traces, by the color of the combination which it forms with certain chemicals. Dextrose furnishes furfurol reactions with alphanaphthol, thymol, xylidin, and under certain conditions also with resorcin.

The reaction with alphanaphthol: If 1 c.c. concentrated sulphuric acid is allowed to run beneath 0.5 c.c. of a diluted sugar solution containing one drop of a 15 per cent. alphanaphthol solution, there appears at first on the line of contact of the two fluids a greenish coloration, which, however, does not pertain to the reaction, and afterward above the latter a ring of dark violet. If the contents are now shaken together the mixture assumes a carmin-red coloration with a bluish hue. Spectroscopically a narrow band between D and E, disappearing afterward, and darkening, beginning at F and extending to the violet end, is noticed.

Notes.—The urine should be rendered free of albumin. The green coloration at the point of contact of the two solutions is caused by nitric or nitrous acid contained in the sulphuric acid. The reagents should be chemically pure and the test-tubes should be boiled in distilled water and thoroughly cleansed before the test is applied. The colorations are best seen in strong light before a white background — sheet of unruled white paper. Carbamid, uric acid, creatinin, xanthin, allantoin, phenol and hippuric acid do not interfere with the test.

Disturbing factors and sources of error.—Other carbohydrates, glycosides, serum albumin, peptone, some unknown urinary constituents.

The reaction with thymol: Two drops of a 15 to 20 per cent. alcoholic solution of thymol are mixed with 1 c.c. of the suspected urine, after which concentrated sulphuric acid is added. On shaking, a vermilion-, or rubin- or carmin-red color of the mixture ensues.

Note.—Thymol is not very well adapted for the detection of the carbohydrates in urine as the color reaction may not be distinguishable from the coloration which urine attains with sulphuric acid alone.

Disturbing factors and sources of error.—The same as with alphanaphthol.

The reaction with xylidin: Strips of paper are dipped in a mixture composed of equal volumes of xylidin and glacial acetic acid to which some alcohol has been added. After the papers have been completely dried they are exposed to the vapors of furfurol—the urine having been warmed previously with strong sulphuric acid. Furfurol turns the papers red.

Disturbing factors and sources of error.—About the same as with alphanaphthol.

HORSLEY-PRATESI'S TEST.

This test depends upon the reduction of potassium bichromate by the products of sugar decomposition. Potassium hydrate 2.5 grams are dissolved in 60 grams of a very strong solution of potassium silicate—waterglass solution—to which 2 grams of potassium bichromate is then added. The solution must be kept in a tightly stoppered bottle. A small sheet of tin is cut into strips, each measuring about 7 cm. in length and 1 cm. in width. A drop of the reagent is placed with a glass rod on the end of one of the strips of tin and there dried by holding it over a small flame. Four more drops of the reagent are allowed to evaporate on the same spot. When the dried reagent on one of these prepared strips is heated it swells up and assumes a distinctly yellow color. When testing for glucose, the suspected urine, drop by drop, is allowed to come in contact with the reagent heated; heat being applied after each additional drop of urine, to facilitate evaporation. A green coloration makes its appearance when sugar is present in the proportion of 0.5 per cent. and over.

Disturbing factors and sources of error.—Albumins, glycuronic-acid combinations, pigmentary bodies.

THE FERMENTATION TEST.

This is one of the most reliable tests for the detection of urinary glucose provided the latter occurs in quantities above 0.5 per cent. Certain vegetable organisms by their vitality call forth disintegration of grape-sugar. The products of decomposition vary according to the species of organism present. Beer-yeast breaks up the sugar molecule into carbon dioxid, and alcohol in neutral or faintly acid solutions. In the main the fermentation occurs thus: $C_6H_{12}O_6=2C_2H_6O+2CO_2$. Lactic acid yeast converts glucose into lactic acid; lactic fermentation may take place in diabetic urine if ammonium carbonate has replaced the latter's carbamid. Butyric acid yeast converts sugar into butyric acid. Mycoderma aceti causes conversion of dextrose into an acid identical with glucinic acid. Kefyr produces fermentative changes of glucose. A number of other specific micro-organisms cause specific fermentations. The fermentation test for urinary glucose is made with fresh beer-yeast, or with dried German yeast, a combination of beer-yeast and dry starch, at a constant temperature of 33 to 35 C. For qualitative testing the fermentation tubes devised by Fritz Moritz[11] suffice. The determination of dextrose by collecting and measuring the carbon dioxid evolved during the process of fermentation may be approximately done with Einhorn's or Fiebig's saccharometers. The method of determining the amount of glucose by the evolved carbon dioxid must always remain inexact, as the yeast *per se*, no matter what precautions are taken, furnishes small amounts of alcohol and carbonic acid gas. Einhorn's apparatus presents a further disadvantage in its open bulb, which permits the escape of considerable quantities of carbon diozid. The detection and determination of glucose by Robert's method—by ascertaining the density of urine before and after fermentation and by calculating the urine's contents of sugar by the loss of specific gravity during fermentation—is by far the most practical and trustworthy means in the hands of the general practitioner. Lohenstein and Stern have devised apparatus for the more practical and convenient application of this method. Stern's apparatus, moreover, may be utilized for the *detection* of glucose only, by interrupting the fermentation after an hour or so and by ascertaining any decline in the specific gravity of the dextrose solution.

Disturbing factors and sources of error.—Maltose, fructose, and similar carbohydrates ferment with commercial yeast. The process, however, is a much slower one. It happens occasionally that a urine containing glucose is not fermentable. This is due to anti-fermentative agents, as salicylic acid, salol, arbutin, extractum myrtilli, etc., after their internal administration.

Polarization.—The value of polariscopy for the detection of urinary dextrose is dependent upon the sensitiveness of the instrument used. Diabetic urine is dextrarotatory. If the urine is light shaded and transparent the examination may be made without further manipulations; if, on the other hand, it contains proteid material and pigmentary substances in excess, they should be first eliminated. A 10 per cent. basic lead acetate solution and repeated filtration is used for this purpose.

Disturbing factors and sources of error.—Not every rotation of polarized light toward the right is due to the presence of glucose, as other dextro-rotatory constituents may occur in the urine. Pronounced rotation to the right, however, is conclusive evidence of the occurrence of dextrose. Maltose, lactose, dextrin, and glycuronic acid turn the polarized ray to the right. The urine may also be dextro-rotatory after the ingestion of certain drugs, especially alkaloids or glucosids; morphin has been found to be optically active in this manner. Dextro-rotation due to urinary glucose may be averted or neutralized by simultaneous occurring levorotatory substances, as proteid bodies, levulose, beta oxybutyric acid, cystin, and some medicinal agents.

SUMMARY.

The brief discourse upon the nature and value of the most frequently applied tests for the detection of urinary glucose divulges the important fact that there is not a single method which is entirely free from possible sources of error. Some of the processes for the recognition of grape sugar in human urine, it is true, possess considerable value and are relatively trustworthy; perfection, however, is not found in any. Absolute reliance can therefore not, and should not, be placed on any single test. Among the numerous methods in vogue, three especially are of considerable value, namely, Nylander's, Penzoldt-Rubner's and the fermentation tests. The great value of Nylander's modification of the bismuth test is virtually but an indirect one—*the nonreduction of the bismuth salt being positive evidence of the absence of pathologic amounts of dextrose.*

its limit of reliability is more extended. Although a single testing method *per se* can never furnish positive proof of the presence of urinary glucose, especially when this occurs in amounts less than .5 per cent., a number of judiciously selected control tests cautiously applied may complete the identification.

For the positive recognition of dextrose in human urine—in routine work—I proceed in the following manner: About 15 c.c. of the freshly voided, non-ammoniacal urine is boiled and filtered. To a portion of the filtrate Nylander's test is applied. If, after prolonged boiling the precipitate retains its white color, I stop with the testing there and then, as no pathologic quantities of grape sugar are contained in the urinary fluid. If, however, the bismuthic salt has undergone even a slight reduction, another portion of the filtrate is subjected to the modification of the Penzoldt-Rubner process described in the foregoing. In case the careful and repeated application of this test yields but negative results, it may be concluded that the urine is free from dextrose. On the other hand, if a pinkish spot has appeared on the heated region of the sediment, indicating the presence of either glucose or of a glycuronic-acid compound, a fresh portion of the urine is boiled, filtered, and subjected to the fermentation test in the urinoglucometer. If after the apparatus has been placed for a few hours under the proper temperature, the urine does not show a reduced density, either no glucose at all or in amounts less than .5 per cent. or anti-fermentative agents are contained in it. A loss in specific gravity taking place soon after subjecting the urine to fermentation points with certainty to the occurrence of grape sugar in quantities above .5 per cent.

The urine, it is needless to say, must be in all instances a sample of the 24-hours product and the patient during the day of its collection and the 24 hours preceding it should not be under the influence of any medicinal substances.

In case the fermentation process, on account of its limitations, does not confirm the results obtained by the Penzoldt-Rubner test, in order to positively identify the dextrose I proceed at once to separate it from the urine. The isolation of glucose from the urine is accomplished by first condensing the same to the consistency of a thin syrup, after which about half its volume of ether is added. The mixture is then allowed to evaporate. At the end of a few days or a week all the syrup has crystallized. The granular mass is now treated with a small amount of alcohol to effect the removal of carbamid and extractive matters. Following this the residue is dissolved in boiling alcohol, the solution filtered while hot and the filtrate permitted to crystallize. The separated cystals are then repeatedly subjected to crystallization from alcohol, or preferably, methyl alcohol. Dextrose thus obtained is anhydrous, colorous, and forms four-sided transparent prisms; the crystals are closely grouped in little white, nodular masses, are hard, become less transparent and liquefy when exposed to moist air, melt at 144 to 146 C., and do not readily dissolve in water. In cold alcohol the crystals dissolve with difficulty, but are readily soluble in boiling alcohol. They dissolve slowly but in large amounts in methyl alcohol and are insoluble in ether. When carefully applied and with sufficient amounts of suspected fluid, this process may yield positive results even with normal urines. Insignificant quantities of dextrose crystals are, however, of no pathognomonic value.

If somewhat quicker results are desired, than with the confirmatory process just mentioned, I try to isolate the dextrose from the urine in the form of lead saccharate, $(PbO)_3 (C_6H_{12}O_6)_2$. This method, however, is inferior to direct crystallization, as from 33 to 50 per cent. of the sugar is lost in the course of the process and as the deposit also contains urinary constituents other than glucose; principally indoxyl sulphonic acid.

Plumbic saccharate is best obtained from the urine in the following manner: An excess of saturated (by heat) solution of lead chlorid is added to 250 c.c. of fresh urine. The precipitate is then separated on a filter and the filtrate treated with ammonium hydroxid. Following this the precipitate is collected, washed, and suspended in water and decomposed either with oxalic or sulphuric acid or with hydrogen sulphid. By treating with calcium carbonate an eventual excess of oxalic acid, and by adding a concentrated solution of neutral lead acetate an excess of sulphuric acid is removed. After another filtration the filtrate is boiled to effect the separation of the excess of hydrogen sulphid. The filtrate reduces Fehling's solution.

Dextrose may be separated from the urine in a variety of other combinations; for instance, as sodium-chlorid-dextrose—$(C_6H_{12}O_6)_2NaCl+H_2O$—as potassium dextrose—$C_6H_{11}KO_6$—as cupric-hydroxid-dextrose—$C_6H_{12}O_65Cu(OH)_2$, and as benzoyl-dextrose. In my experience, however, the repeated crystallizations from alcohol or methyl alcohol is the most simple and at the same time the most reliable method for the preparation of the urinary glucose.

If after several attempts I have not succeeded in isolating glucose from the urine, I proceed to qualitatively determine the urine constituent or constituents which have caused the reaction. Quite a number of urinary substances other than glucose may bring about a reduction or pseudoreduction of the bismuth salt. The Penzoldt-Rubner test, at its worst, only reacts with two other urinary constituents—glycuronic-acid combinations and indoyxl in excess. In case this test has given positive results which as afterward proved were not found due to the presence of sugar, I make a search for the glycuronic-acid compounds and for indoxyl. I ascertain the nature of the bismuth reducing agent or agents, only when no reaction has occurred with the Penzoldt-Rubner test. The tests for indoxyl and some of its compounds are simple. I have already described a method for the detection of this urinary constituent.

It is a simple matter to differentiate between urinary glucose on the one hand and glycuronic acid or any of its compounds on the other, provided the former occurs in the proportion of .5 per cent. and over, as the latter do not ferment with alcoholic yeast. However, if glucose is present in but minute quantities, it is often very difficult to identify the glycuronic-acid combination, as it possesses reducing qualities similar to dextrose. The glycuronic-acid combinations are found in strongly levorotatory urines only, and they may thus be recognized. Glycuronic acid, *per se*, is, like glucose, dextrorotatory.

The identification of dextrose in human urine can not be accomplished by any single test. The copper tests, as Fehling's, Pavy's and Purdy's, serve admirably when employed for quantitative determination after identification has taken place. The employment of a copper test without a control process, even in mere routine work, is objectionable. How we are all apt to wrongly interpret a copper test is drastically shown by the following illustration:

A woman, aged 63, affected with diabetes mellitus for several years, was referred to me by her family physician.

A careful urinary analysis, made after the positive recognition of dextrose, revealed the presence of 101.82450 grams of this substance in 1925 c.c. of urine, the diurnal output. The patient was placed on a diet rich in proteids and fats, and at the end of one week, the urine was again subjected to examination. The patient was anxious to know the result of her week's dieting before she left for home—a neighboring town—and I myself, having been greatly pressed for time, applied Fehling's test. Reduction soon occurred and the patient was advised to continue with the rigid diet. A week after, under similar circumstances, on the application of the same test, reduction again ensued. The patient who positively denied having ingested any carbohydrates, remonstrated on being told that she had to still continue her abumin-fat diet, and gave me to understand that she would cease dieting. A more careful examination of the urine several hours after her departure pointed out the absence of glucose but revealed the presence of creatinin in excess—the true reducing agent. Undoubtedly the enlarged consumption of meat had given rise to an increased amount of creatinin. Thus, through sheer neglect a patient came nigh leaving me.

The concomitant phenomena of a supposed glycosuria are not always well pronounced and the diagnosis hinges, therefore, solely on an examination of the urine. In other instances where the symptoms unmistakably point to diabetes mellitus and the behavior of the urine to the different reduction tests is indicative of the presence of glycosuria, we may well assume the presence of this affection. However, without its definite identification we are never certain that glucose is the real reducing factor.

My experience does not tally with that of Saundby,[12] who maintains that during the many years he has devoted special attention to urinary diseases and diabetes, he had never seen but sixty-nine specimens of non-diabetic urine which reduced copper. I do not know what proportion these sixty-nine instances form of the total urinary examinations conducted by Saundby, but I assert that every sixth or seventh case of "diabetes" referred to me for treatment is neither diabetes nor glycosuria, and that the urine of the majority of these patients reduces copper in an alkaline solution.

Viewed in this light, we may readily understand some of the occasional spontaneous cures of diabetes, as these cases, in all likelihood, were but those of pseudoglycosuria. Pseudoglycosuria, however, is a negation in itself, an affection which does not exist, a euphemism for a reduction test erroneously interpretable or interpreted.

The identification of glucose in human urine has not been accorded the attention which its importance might demand, and a great deal can still be said and remains unsaid by me on this subject; but I feel that I have already transgressed beyond the limit of your patience. If you, however, agree with me as to the importance of this theme, you will not find me guilty of having carried coals to Newcastle.

56 East Seventy-sixth street.

Diagnosis of Stricture of the Esophagus.—Pauli has found that a stricture of the esophagus can be diagnosed by having the patient ingest 80 to 100 c.c. tartaric acid, and then in twenty minutes a solution of potassium bicarbonate. If the esophagus is freely permeable, nothing unusual is observed in consequence, but if there is a constriction, the mouth fills with foam from the effervescence.

The Cash Value of an Infant's Life.—Are more than nominal damages recoverable for the negligent killing of an infant incapable of earning anything, without direct evidence of pecuniary damage other than sex, age, and condition of health of the infant at the time? This was the contested question presented to the Supreme Court of North Carolina by the case of Russell vs. The Windsor Steamboat Company. Here, a male child five months old had been killed by the alleged negligence of the company, and the father brought this action to recover damages. However, he did not try to enforce the common law remedy, to which the court says that he would probably have been entitled, of an action based upon a loss of services. Instead, he sued as administrator, under the North Carolina statute, which does not regard the family relation, but gives the cause of action to the personal representative of the deceased, without distinction as to age. Thus, the case was made purely and simply one to recover the net value of the child's life—not what his services might have been worth to some one else during his minority, but what his entire life would have been worth to himself, had he lived. In other words, this action was brought just as it would have been had the one killed been of adult age. Now, suppose, says the court, that the child had survived; but as a cripple, condemned to a life of dependence, and perhaps of pain, could he not have recovered damages in a suit by his next friend. If so, could not his personal representative recover them under the statute mentioned? The court holds that he could. It declares that it sees no distinction in the law, nor reason for distinction, between the death of a child and of an adult. The measure of damages is the same, though, it is frankly admitted, the difficulty of its application is greatly increased in the case of an infant. Still, the court continues, the jury must do the best they can; taking into consideration all the circumstances surrounding the life that is lost, and relying upon their common knowledge and common sense to determine the weight and effect of the evidence. Where life is lost by reason of the actionable negligence of another, the measure of damages, it holds, is the present value of the net pecuniary worth of the life of the deceased, to be ascertained by deducting the probable cost of his own living from the probable gross income derived from his own exertions, based upon his life expectancy. The expectancy of an infant of five months, it adds, is a matter of evidence, like other circumstances of health, constitution, and habits. Then, the court says, there is another view of the question which forces itself upon its mind. This, perhaps, it was not called upon to consider; but, unless forced to do so by the overwhelming weight of authority or the inexorable logic of legal conclusion, it insists that it would be reluctant to admit that a human life, however lowly or feeble, had no value, in the contemplation of a common carrier. Even a new-born colt or calf has an actual value, entirely dependent upon its future usefulness or salability. The court also says that it is a matter of common knowledge that during the days of slavery a healthy negro child, even at the breast, was considered as worth at least $100. It then suggests that this contrast be considered. A helpless negro baby, lying upon the floor along which he could not crawl, and born to a state of hopeless bondage, was worth to the owner at least $100 as a chattel; and yet another baby, with generations of inherent qualities behind him, and the magnificent possibilities of American citizenship before him, is not worth to himself, or to the country whose destinies he might one day have shaped, even the penny necessary to carry the costs. This view the court pronounces entirely too incongruous to strike its fancy. Wherefore, it holds that the plaintiff was entitled to recover substantial damages, and affirms a judgment in his favor for $1000.

PNEUMATOPATHOLOGY.

Many pathologic conditions in various parts of the body are associated with the production of gas, even where gas is normally absent. There has been much discussion concerning such mysterious conditions by writers of the past, the problem being mostly whether the gas was atmospheric air or of putrefactive origin. With the advent of bacteriology the solution of this question, at least in some of its phases, was to be expected; and the discovery by Welch, in 1891, of the bacillus aërogenes capsulatus has already thrown much light on gaseous affections and processes. In the Shattuck Lecture, 1900, Welch[1] gives an extended review of the morbid conditions caused by this bacillus. There is no question that this organism is the one most frequently at work in cases of abnormal gas-production in the tissues; and its causative rôle is definitely established. The number of morbid conditions produced by it is large and varied, many of them of great clinical importance and heretofore poorly understood. The natural habitat of the bacillus is the intestinal canal and the soil, hence the liability to frequent infection. An important biologic property is its power to form gas from proteid materials.

In the first place it is notable that the organism may produce gas bubbles throughout the blood and the organs—"foamy organs"—within a few hours after death from the most varied causes. Formerly these cases were explained as the result of air embolism, especially in pregnant and puerperal cases. Whether the invasion of the bacilli and the development of gas are antemortem or post-mortem phenomena can not always be determined, but Welch concludes that in most cases of this sort the invasion of the bacilli occurs post-mortem or shortly before death. The bacillus aërogenes capsulatus being anaërobic, it is not likely that it multiplies in the circulating blood, but there is no valid reason against its multiplying during life in internal organs, such as the liver. Examples of the bacillus having been carried from an infected portal of entry to distant parts where necrosis and emphysema were produced have been detailed by various observers. Great care must be taken to distinguish between air embolism and gas bacillus invasion; this would generally require a careful bacteriologic examination.

"It is as a cause of that most dreaded of wound complications, emphysematous gangrene, that B. aërogenes capsulatus especially claims the interest of surgeons." Recent investigations show that most cases of emphysematous gangrene are caused by this bacillus and not by Pasteur's "vibrion septique," also called bacillus of malignant edema—Koch and Gaffky. Cases of gaseous phlegmons occur occasionally, especially in our large hospitals, but also elsewhere, and they merit study by exact bacteriologic methods in order that their etiologic relations may be cleared up fully. Welch has collected 56 cases of emphysematous gangrene associated with B. aërogenes capsulatus; the majority of these cases are American, and naturally all occurred since 1891. In all but 5, these cases followed traumatism or surgical operation, the infection generally occurring from without; in a few cases it undoubtedly came from the intestine. Mixed infection is common in this series, but the disease is really sui generis. Death occurred in 59.5 per cent., being caused probably by a toxemia. There is no proof that gaseous embolism may cause death in cases of this sort. It is of great importance that an early diagnosis be made so that radical measures may be instituted in time.

Important uterine infections may result from B. aërogenes capsulatus. Welch considers separately emphysema of the fetus, puerperal endometritis, physometra, emphysema of the uterine wall, and puerperal gas sepsis. There can be no question that many, if not most, cases reported as death from air embolism following abortion and labor are instances of invasion with Welch's bacillus from the uterus.

The urinary tract may become infected with the gas bacillus, which may then spread into adjacent tissues and into the circulation. Gas may be free in the cavity of the bladder, the ureters or renal pelvis, or contained in submucous blebs.

Another starting-point of invasions of B. aërogenes capsulatus is *the gastrointestinal canal, which* frequently, if not constantly, harbors the bacillus; hence the intestine is the most frequent source of the bacilli in the gaseous blood and foamy organs found at autopsies. There may also be local gastrointestinal lesions with or without gas cysts. Pneumoperitonitis with or without perforation occurs, and the gas bacillus may invade the bile-ducts and gall-bladder, especially in the case of diseases of and operation on these structures. Gas cysts of the genitourinary, gastrointestinal and biliary tracts, submucous and otherwise, due to the gas bacillus, constitute an interesting series of lesions. Levy has demonstrated B. aërogenes capsulatus as a cause of pneumothorax with perforation, and similar cases are referred to by other writers. Gwynn found Welch's bacillus in the blood during life, and Welch expresses the suspicion that Achalme's anaërobic bacillus found in acute articular rheumatism is identical with the gas bacillus. Howard and others have found the gas bacillus in pure culture in meningeal exudates, thus bringing further evidence of the pyogenic powers of the organism; and the bacillus may also cause cavities in the brain—Reuling and Hering[2], Howard.

---

[1] Boston Med. and Surg. Journal, July 26, 1900; also Johns Hopkins Hospital Bulletin, Sept., 1900.

From this imperfect enumeration of the various lesions considered by Welch and caused by the bacillus aërogenes capsulatus, it is seen that pneumatopathology at present is dominated by this organism, a knowledge of whose characters and properties is essential for a full understanding of many important processes. Although described fully in 1891 and since made the subject of numerous papers in American journals, knowledge of the gas bacillus of Welch has been very slow in reaching workers in other lands; and throughout his lecture Welch repeatedly calls our attention to the erroneous conclusions and incorrect statements made by French and German writers on account of their ignorance of American publications.

THE RELATIONS OF SCIENTISTS TO NEWSPAPERS.

The deep-seated feeling in the medical profession against the newspaper as a purveyor of information concerning medical matters and the doings of medical men in general rests on the knowledge that in the majority of cases the motive underlying such publications is of a largely selfish and commercial nature, subversive of the true interests of medical science. Unfortunately, the newspaper does not consider the question in the same light. Its chief aim is to give publicity to anything that its editor thinks may please the omnivorous public. Knowing that the general run of its readers are incompetent to discriminate between genuine achievements and pure bluff and braggadocio, the inquisitorial reporter—than whom there is no greater heresiographer—is detailed to interview alike the true man of science and the mountebank. Rocky Mountain goat's lymph, wonderful operations, and studies in chemical and other forms of artificial fertilization are heralded in display type and in the same sensational manner, so that it appears as if seekers of cheap notoriety had secured a foothold even in our great universities—"quacks political; quacks scientific; academical."

Notable achievements of whatever nature, be it physical, biologic, or more exclusively medical and surgical, merit full publicity. The citizens of the community are entitled to learn of remarkable and important additions to knowledge made by men at work in their midst, perchance at institutions in which the public is and has a right to be interested. It ought to learn that progress is being made and that scientific pursuits are flourishing. Information of this sort is encouraging and stimulating; it breeds confidence in home institutions and creates a wholesome interest in their welfare. But this information should be made public in a manner and taste befitting its scientific character and the modesty that the scientist is traditionally reputed to manifest in his own work and personality—a tradition not wholly of the past but illustrated well even at the present time and by men that for this very reason not infrequently are *greatly misrepresented by the harmful activity* of overzealous assistants and local press bureaus.

There is always good occasion for earnest pleas in favor of modification in the editorial management of our newspapers in respect to matters of this kind. The fundamental and far-reaching importance of truth and the wholesome effect of tasteful moderation in statement seem to be sadly neglected in the education of journalists of the present day. Clear, concise recitals of notable work in these various fields of science including medicine, shorn of all irrelevant embellishments and superlatives, carefully edited by competent persons and signed by the authors, would remove many of the serious objections that now hold against the newspaper as a medium of dissemination of scientific knowledge. But how and when are we to expect so much consideration for the right and proper on the part of a press sunk so low in commercialism that it preys on the health of its readers by accepting advertising patronage from the most shameless frauds—patent-medicine makers and quack doctors?

THE MARRIAGE OF CONSUMPTIVES.

A leading daily paper publishes what purports to be the opinions of certain noted European authorities on the question: "Should consumptives marry?" These are, naturally, unfavorable. There are few, if any, physicians who, if asked their general opinion as to the propriety of a consumptive marrying, knowing himself to be such, would care to give a favorable reply. The probabilities of good resulting to the individual, as far as his or her physical welfare is concerned, are practically *nil*, while the perils of the marriage state are very real for the husband and still more so for the wife. When, however, the question is an actual and practical one we fear there are many physicians who would feel embarrassed and would prefer to avoid the responsibility of expressing an opinion in a given case. While on the one hand we have the possibilities of direct aggravation of the disease, the dangers of communication to a healthy partner, the prospects of early bereavement and distress, and lastly the real though remote possibility of direct transmission to offspring, and the probably still greater danger of transmitting a weakened and predisposed constitution, yet we have numerous instances of marriages where none of these consequences ensued, and some where the result was an apparent betterment of conditions in all respects. It may, as Professor von Leyden is quoted as saying, be best not to be too positive and to consider that medical advice on this subject is apt to be disregarded, and if the physician insists too much he may succeed sometimes "only in fashioning a wedding gift that may turn out a cross by and by; the thought of disease lurking in the beloved husband's or wife's every caress," out of which no good can come. [illegible] stic[illegible] to [illegible] actual outcome of happiness in [illegible] is one that no physician can [illegible] that a favorable balance is sometimes struck, with all the apparent conditions to the contrary. This may serve us for consolation when we consider how many such marriages are constantly taking place.

---

[2] THE JOURNAL, Vol. xxxii, p. 1603.

Leaving aside, however, the problems that involve only the contracting parties, there still remains the very serious question of the interests of those that are to be the offspring of such unions. No one "liveth to himself or dieth to himself," and this is especially true of the married consumptive. It is customary nowadays to consider only the bacterial causes of consumption, and a certain class wedded to the idea of a hypothetical germ plasm deny that acquired characters can be transmitted, thus discrediting the possibility of the direct heredity of the disease otherwise than through actual transmission of its germs. All pathologic and clinical experience is against them; there is nothing more certain than that disease of the parent modifies the constitution of the child, often producing an actual homologous morbid heredity, as is particularly observed in insanity and some nervous and other disorders. There is a growing tendency to consider the incidence of consumption as depending more on the soil than the germ, and there is nothing more certain than that it sometimes transmits to offspring a weakness or predisposition to itself and to other constitutional diseases. If the infection were always fatal few would escape, but it is harmless to the most of us in spite of ample exposure. The popular notion of the heredity of the disease, however, is based on actual experience and observation, though it is not the disorder itself but the prepared soil for it that is transmitted. This fact adds very much to the responsibility of those who propose to advise the marriage of consumptives, and while we can have no certainty that the children of such a union will suffer for their parents' disease, we must recognize the fact that as compared with others they often enter life under a serious disadvantage. This alone should be enough to make us use our influence against the possibility of the begetting of future victims.

We have not used the words "tuberculous" or "tuberculosis" here, because they have a much wider significance and by no means so serious an import. Many people suffer or have suffered from tuberculosis in one form or another where it is a comparatively trivial affection, and in some the course of genuine pulmonary infection only shows the strength of their constitution and resisting powers. These remarks apply only to those who are the subjects of true pulmonary phthisis.

THE OCULIST AND THE OPTICIAN.

The relations that exist betwen the physician and the druggist to whom he sends his patients for prescriptions, find a parallel in the ophthalmic surgeon who directs his clients to a particular optician. The same ethical code that regulates, or should govern, the doctor and his patient equally applies to the oculist and his patient. It seems necessary to add, moreover, that the laws of the codex, to be effective, should be based on the experience of years and should stand the application of common sense. It is not enough that the professional man should accept the code of ethics as he might any other authority; it is not sufficient that these rules should be simply organic with him, as the result of their reiteration since he began the study of medicine, because he must often furnish to lay persons good and sufficient reasons; for such action, based upon them, is expected to influence the conduct of himself and others. He must lay bare the foundations of the faith that is in him.

Apart from the canons of the code, why is it that every community, after considerable experience of the various methods of regulating the business relations of physicians and druggists, has concluded that it is not only against the public policy, but inimical to the best interests of the medical profession, to pay a commission on prescriptions sent to him by the physicians? Although we commonly say that the acceptance of such a commission is objectionable because it is contrary to the code of ethics, we do so with the proviso that it is equally opposed to the dictates of the medical conscience and to the experience of everyday life.

When it is asserted by the optician that there is nothing wrong in the payment of commissions to ophthalmic surgeons who send him prescriptions for eyeglasses and spectacle lenses, the answer must be somewhat different from that which would be given to a member of our profession. One might expect the latter would accept the united experience of his confrères in all countries as a reply to such an assertion; if not, he must, in common with the laity, be asked to consider for a moment what an action of this sort implies, and what the patient who pays the bill would think of it and those who have been a party to it. Furthermore, we can not avoid the inquiry as to what effect such a transaction will have on the prescribing surgeon and the profession to which he belongs.

When the patient pays the ophthalmologist for his services and receives from him a prescription for glasses, he has a right to expect, and does expect, that the surgeon will direct him to an optician who will fill the prescription at a fair market rate and that the transaction is then entirely between the optician and himself. When a commission is paid, either the patient gets that much less in the quality of the goods or in the attention that is paid to him, or is charged just so much more than he ought to be, usually under some false pretense or other. The other alternative proposition, that the optician "divides" his profit with the oculist, is probably never true. In the end it will be found that the patient gets less for his money than he ought to, that the optician charges more than he should, and that the dubious difference is stealthily handed over to the ophthalmologist. Surely such an underhand proceeding is unworthy the practitioner of a profession like ours, and it hardly seems possible that for the sake of a few dollars any right-minded man would be willing to countenance it. Beginning with a breach of confidence on the part of the physician himself, it terminates in an undignified performance that reminds one of nothing more than the storekeeper's commission to the false guide who steers the unsuspecting customer into his shop. The above comments are called forth by a "Query" on p. 783.

MEDICAL ORATORY.

We publish this week an article on "Physicians as Speakers," which can be recommended as instructive reading. The medical is the only one of the three learned professions that pays no attention to oratory, and popularly, as well as in the profession itself, the idea prevails that a physician has no need of any accomplishments in that direction. Mr. Whitford shows from a reporter's standpoint how erroneous this notion is; he makes it plain that for the physician who is to take any active part in the progress of medical science a pleasing and effective elocution is in no sense a useless accomplishment. The higher a man rises in the profession, the more essential he finds such ability; he may be eminent as an investigator, a practitioner, and a writer, and yet be seriously handicapped in comparison with men far below him in all these respects by the lack of power, of command of language, and easy and attractive delivery. A great engineer once said, when worsted in argument by those whose opinions on the subject he could not particularly respect: "There is no gift like the gift of gab." This is a rough statement of a very much more serious truth than was sarcastically implied by its utterer. It was the gift of speech that raised man above the brutes, and it is the same, even in these days of printer's ink, that still often raises man above his fellows. The medical profession may not demand, as generally as the others, oratorical accomplishments of its members, but it does call for them to a certain extent, It is not alone, however, for medical meetings, college lecturing, etc., that the physician requires a proper elocutional training; the profession is constantly coming more and more to the front as a public educator and administrator of affairs, and here the value of such training is most manifest. No medical man will be the loser for having such an accomplishment, and the world would be a gainer if more of us had it. It is well, in this regard, to see ourselves as others see us, and for this reason alone the article should be profitable to our readers.

RAILWAY SANITATION.

It is said that at least two railroads in this country propose to remodel, or at least modify, their passenger coaches on sanitary lines. The plush upholstering, elaborate dust-concealing grill and carved work, heavy carpets and curtains are to be replaced by leather, smooth woodwork, linoleum, etc. The public will probably miss some of the splendor of the old régime, but this will, we trust, be more than compensated for by the greater sense of safety they will feel from contagion. There will be more than this needed, however, to bring railway travel up to the constantly widening sanitary ideals of the present day, and these can hardly be met in full without the active co-operation of the traveling public. The common drinking-cup may be replaced, as has been suggested, by the cheap paper substitutes for individual use, and possibly individual soap and paper towels may come into use on the sleepers, but the day cars with their constantly changing inmates are a more puzzling problem. What to do with the expectorators is one question. Judges have decided that the right to spit is inherent, and if it is to be restricted receptacles must be provided. Will the railroad authorities attach a disinfected cuspidor to every seat, or will they require expectorators and smokers to herd together? This question is as important as any one that is to be considered in the sanitation of railway carriages, though there are others generally treated as more important. The spitting habit is the most common of all insanitary nuisances, and it ought to be one of the first taken in hand in the reform. A passenger can protect himself by carrying his own drinking-cup, as well as brush, towel and soap, but he would not like to be compelled to carry a cuspidor for his neighbor's use, and he can rely on it that the average expectorator will never carry one for himself. We expect, however, to see the sanitary reform progress, and it may be that it will meet this evil as well as others.

THE EVILS OF TIGHT LACING.

While it might not be easy to give a succinct definition of the "new woman," she may be described as one who has been emancipated from the bonds of tradition and has been permitted to find the place of usefulness in the world that she is capable of filling; and there is not wanting evidence that she has profited by the new opportunities thus afforded. In one respect, however, she has, as yet, failed to exhibit her independence and her strength, and that is in her continued and almost abject submission to the dictates of fashion, regardless of hygienic considerations. For instance, can anything be more conceivably dangerous than the trailing skirts with which women have so largely of late swept filthy streets, raising clouds of bacteria-laden dust, and carrying into their homes the agents of disease and death? Further, in spite of all the denunciation that has been heaped upon the practice as non-hygienic, and notwithstanding the admonition of competent authorities, the large body of women persist in the use of the corset and of unduly constricting and otherwise irrational forms of clothing. It is true, a strong counter-current has set in, and shorter and properly supported skirts, as well as other reforms in the wearing apparel of women, have been adopted, but they are not nearly so numerous and so universal as they should be. Some experimental observations made by Thiersch[1] illustrate the evils resulting from constricting clothing, and more especially the use of the corset. These consist more particularly in compression of the chest, with interference with respiration and circulation; in enfeeblement of the extensor muscles of the back, with difficulty and discomfort in maintaining the erect posture; in interference with the circulation and the nutrition in the compressed skin, as well as with the circulation in the portal system; in displacement of the intestines downward, and distortion of the liver and stomach, with digestive derangement and dislocation of various abdominal viscera. It is not denied that under certain exceptional conditions the corset may subserve a useful purpose, as in obese and well-built and well-developed women; but under no circumstances should its use be permitted to girls during the developmental period. Reform in this direction has already begun, and it can not be too speedily carried to a successful termination.

---

Medical News.

The Journal in the Literary Exhibit at Paris.—We have just received the following announcement from Paris: "I have the honor to inform you that in accordance with the official announcement of awards at the Paris Exposition of 1900, a Grand Prize was bestowed upon the exhibit of United States journals, publications and periodicals, and that you are therefore entitled to use this award of Grand Prize." Signed, A. S. Capehart, Director of Liberal Arts and Chemical Industries.

The Maharaja of Jaipur has given 15 lakhs of rupees, equivalent to $500,000, toward an "Indian People's Famine Trust."

Dr. Rudolf Virchow's golden wedding was celebrated August 24. One son, Dr. Hans Virchow, is professor of anatomy at the University of Berlin; another is Dr. Karl Virchow.

It is stated by the *Medical Press and Circular* that Assistant-Surgeon O'Neill has been murdered by the Boers. He was out with an ambulance in search of wounded. A party of Boers came upon the ambulance, seized it, and ordered the medical officer away. They subsequently recalled and shot him.

Third Pan-American Medical Congress.—The Southeastern Passenger Association has granted a one-fare plus two dollars rate for the round trip to Havana, Cuba, for the December meeting of the Congress. The steamship lines have granted a one-fare rate. The other passenger associations are considering the matter and are expected to grant the same rate.

Dr. John E. Clark, of Detroit, has just returned from Glasgow. He says the city's calamity is great, the schools are closed, and her trade and commerce with the outside world has been closed. Every exertion possible has been made by the health authorities to guard against the spread of the plague. The "contacts" are placed under observation as soon as discovered.

In a Valedictory Address delivered by the late Dr. Jacob M. Da Costa to the graduating class of 1891 at Jefferson Medical College, he said: "A teacher will not simply instruct; he will do more, he will educate. Through his pupils he lives; the man passes away; the teacher remains in his pupils and becomes part of them. When the hour comes that I shall lay down this robe of teaching, when the time arrives that I shall address you no more, there will always remain the thought —I say it in all humility—that I shall live in you. I shall be with you in your struggles, shall share with your successes. At every bedside of distress, at every bedside of hope we meet again. The teacher is inseparably joined to you, to all his pupils. Awful, ever-present responsibility, constant excitant to truthful, arduous effort; and happy is he who has been so guided that he has never forgotten his responsibility nor relaxed his exertion; that he has used God's gift of teaching for God's purpose."

CALIFORNIA.

Dr. Frederick Reynolds, of Los Angeles, late interne at the county hospital, has been appointed assistant-surgeon at the Soldiers' Home.

Dr. Cornelius F. Buckley, one of the pioneer physicians of San Francisco, was badly bruised and cut about the face and body in a runaway accident, September 3.

Dr. Frederick W. Hatch, of Sacramento, now general superintendent of State Hospitals for the Insane, will, it is reported, be made superintendent of the Napa Asylum, to succeed Dr. A. M. Gardner, resigned.

Highland Asylum was found by the State Board of Health to be greatly overcrowded. It was clean and in good sanitary condition. The board recommends that a large wing be erected.

The new Railroad Hospital, which has been remodeled from the old Charles Crocker residence, San Francisco, will be thoroughly equipped and ready to receive patients October 1. The old hospital will be torn down.

The hospital stewards at the Post Hospital, San Francisco, complain that they are obliged to be on duty thirty-three hours out of forty-eight. The watches are divided into stretches of fifteen and eighteen hours. The hospital is crowded and the hospital corps undermanned.

The new operating wing of the Mater Misericordiæ Hospital, at Sacramento, was formally opened on September 8. The suite of rooms comprises, in addition to the operating-rooms, separate rooms for anesthesia, sterilizing, storage of dressings and dressing-rooms for operator and assistants.

The report of the Health Department of Los Angeles for August shows 131 deaths, or a death-rate of 15.26 per 1000. The causes of death were: Specific infectious diseases, 18; respiratory diseases, including 18 from tuberculosis, 32; digestive diseases, 17; nervous diseases, 15; circulatory diseases, 12; genito-urinary diseases, 10; violence, 9. The deaths included 80 males and 51 females. During the month 154 births were reported. The contagious diseases reported numbered 38—diphtheria, 12; scarlet fever, 11, and typhoid fever, 15.

COLORADO.

Gross Medical College, Denver, opened its twelfth annual session, September 12. Addresses were made by Professors Charles B. Van Zant, George E. Tyler and other members of the trustees and faculty.

The August mortality of Denver was 223—128 males and 95 females. Tuberculosis caused 37 deaths; typhoid fever, 9; scarlet fever, 2; diphtheria, 1; pneumonia, 10; cholera infantum, 14, and violence, 13.

CONNECTICUT.

Dr. Joseph E. Root, of Hartford, has returned from a two months' trip to Europe.

Dr. Victor S. Merritt, of Hartford, has bought the practice and property of Dr. Jackson, of Haydenville, Mass.

The State Board of Health report shows that there were 1642 deaths during the month of August. This was 59 more than in July, 260 more than in August of last year and 298 more than the average number of deaths in August for the five years preceding. The death-rate was 31.9 per 1000 for the large towns; for the small towns, 21.1, and for the whole state, 21.7. The deaths reported from infectious diseases were 612, being 37.3 per cent. of the total mortality. The prevalence and mortality of measles, scarlet fever, diphtheria and whooping cough are greatly abated, as compared with the preceding months of the year, but typhoid fever and acute intestinal affections have increased. The typhoid excess is probably due in part to the low elevation of the wells. Other diseases have not varied so conspicuously from their usual prevalence. Typhoid fever is reported as occurring during August in 56 towns in the state, with a mortality of 36, against 21 in August of last year. Several of the patients are reported as taken ill soon after vacations spent away from home. It would be very instructive and profitable if all the reports of typhoid cases indicated whether contracted at home or elsewhere. About a year ago it was stated that a large proportion of the victims of infectious diseases are among those who have been visitors at the different summer resorts in this or neighboring states. The same observation is likely to be realized this autumn, especially in the occurrence of typhoid fever. The unusual high temperature during August has operated with fatal effect on infantile life. Over 43 per cent. of the total deaths were of children under 5 years old. These deaths were, in the majority of instances, caused by diarrheal disorders and induced mostly by food rendered unwholesome by the changes produced in it by heat. Nursing babies and babies well fed on wholesome, unspoiled food do not suffer from hot weather more than adults.

DISTRICT OF COLUMBIA.

DR. D. PERCY HICKLING, of Washington, has returned from his European trip.

THE FOLLOWING general order was issued by the War Department September 10: The Army Medical School is governed by special regulations, and will have the following organization: The faculty will consist of four or more professors, selected from the senior officers of the Medical Department stationed in or near the city of Washington, and such associate professors as may be required. The senior officer will be president and the junior secretary of the faculty. The student officers will be selected by the Surgeon-General from those medical officers who have been appointed since the last preceding term of the school, and such others as may be authorized to attend.

FLORIDA.

DR. MARTIN KENNEDY, of Bartow, will locate in Pensacola.

ILLINOIS.

DR. JOSIAH C. TAYLOR, of Hull, has moved to Rich Hill, Mo.

DR. PAUL DOMBROWSKI, of Peoria, has returned from Paris.

DR. ROY W. RIGGS, of Winchester, has moved to Newark, S. D.

DR. ALVA C. FOSTER has moved from Blue Mound to Columbia, Mo.

DR. CHARLES A. HANDLEY'S office, at Isabel, Edgar County, was destroyed by fire September 2. He lost his library, instruments, medicines, etc., his loss being more than $1000.

DR. JAMES O. DECOURCY, assistant city physician of East St. Louis, resigned his position September 11, because, when he protested against the reduction of his bill for $500 for treating smallpox patients to $250, the board of supervisors still further reduced his bill to $100.

Chicago.

DR. JACOB FRANK returned, on September 15, from his summer in Europe.

DR. WILLIAM L. BALLINGER is lying dangerously ill at the Evanston hospital.

DR. ROBERT D. BOYD has returned after a vacation of a month spent on the Great Lakes.

DR. AND MRS. JULIAN E. HEQUEMBOURG have returned after a summer vacation at the seashore.

DR. J. M. WASHBURNE was married to Miss Margaret Price, of Buckhart Township, September 2.

DR. ROBERT C. WILSON has returned from Lake Harbor, Mich., where he spent July and August.

DR. AND MRS. GEORGE F. FISKE have returned from a two-months' stay in Colorado, and sail for Europe to-day.

DR. CYRENIUS A. DAVID, who has been spending several months in Europe, returned to the city on September 5.

DR. AND MRS. J. ELLIOTT COLBURN have returned from their trip to Europe. After visiting the Paris Exposition they took a 500-mile bicycle trip through southern England and Wales.

DR. OTTO H. PAGELSON, who has recently completed his interneship at Cook County Hospital, has located in Iowa Falls, Iowa, where he will be associated with Dr. Melvin W. Hill.

DR. LEO LOEB, of the University of Chicago, has returned from his sojourn at Woods Holl, Mass., where he has been experimenting on the development of life from unfertilized eggs.

DR. FRANK BILLINGS, who has spent the last two months at Mackinac, for rest and recuperation, has returned. He was ill with malarial fever for several weeks, but has entirely recovered.

DR. JOSEPH HAVEN, United States consul at St. Christopher, West Indies, has been spending a few days in Chicago. He has recovered his health and expects to return to his practice in Chicago early in the spring.

IN MEMORY of Dr. Ernst Schmidt, the trustees of the Michael Reese Hospital have adopted resolutions, setting forth his service as surgeon to the hospital for twenty years, extending the condolence of the officers and trustees to the family and inscribing his name on the hospital roll of honor.

THE COLLEGE OF PHYSICIANS AND SURGEONS will open on October 1 with an estimated total enrollment of 700. In addition to the faculty changes already noted, the following appointments have been made: Dr. Harris E. Santee, professor of anatomy; Dr. John L. Porter, professor of orthopedic surgery; Dr. Joseph M. Patton, professor of physical diagnosis; Dr. Daniel N. Eisendrath, professor of clinical anatomy; Dr. Don L. Shaw, professor of anatomy; Dr. Julius H. Hoelscher, professor of clinical medicine; Dr. Bernard Fantus, adjunct professor of materia medica; Dr. August F. Lemke, adjunct professor of practice of medicine; Dr. Edward H. Lee, adjunct professor of practice of surgery; Dr. James M. Neff, adjunct professor of practice of medicine; Dr. Aristides E. Baldwin, adjunct professor of stomatology; Dr. Eugene R. Whitmore, adjunct professor of chemistry; Dr. Samuel J. Walker, adjunct professor of clinical anatomy and instructor in surgery; Drs. Edward F. Wells, William K. Jaques, and James W. Walker, adjunct professors of practice of medicine; Dr. Leo Loeb, assistant professor of pathology; Dr. William H. Rumpf, instructor of gynecology.

HEALTH DEPARTMENT.

Recent heat and humidity are responsible for the increased mortality from the acute and intestinal diseases. For more than two weeks there has been an almost epidemic prevalence of these ailments, but not until last week did this show an increased number of the diarrheal deaths—116 as against 94 the week previous and 85 during the corresponding week of 1899. Notwithstanding the increase from this cause, the total mortality from all causes numbers only six more than for the first week of the months and the death-rate for the last fortnight is only 13.75 per thousand of the Federal figures of population—1,698,575. The interrupted flow of the drainage channel has had no effect on the sanitary quality of the public water-supply as determined by chemical examination, and the increase of typhoid fever must be due to some other cause—probably the usual seasonal increase. The increase is not great enough to cause alarm, while the comparison with the period before the drainage channel was opened still continues favorable. During the first fortnight of September, 1899, there were 25 typhoid deaths, and during the same period this year there were but 17 deaths from this cause. The mortality for the week ended September 16, was 450, an increase of 59 over that of the corresponding week in 1899, the respective death-rates per thousand being 13.81 and 12.71. Of males 236, and of females 214 died. Under 1 year of age, 120 deaths occurred; between 1 and 5 years, 67; and the same number over 60 years of age. The principal causes of death were: Acute intestinal diseases, 116; consumption, 40; cancer, 35; heart disease, 31; nervous diseases, 28; violence, 21; Bright's disease, 15; pneumonia, 14; apoplexy, 11; typhoid fever, 10; diphtheria, 7, and suicide, 7. During the week 66 cases of contagious disease were reported—scarlet fever, 28; diphtheria, 37; whooping-cough, 1; typhoid fever, 13. At the stockyards 62,202 pounds of meat were condemned. Of the 454 samples of milk [illegible], 9.C per cent. were found to be below g.

INDIANA.

Dr. F. Blair Humphreys has moved from Fremont to Angola.

Dr. Minor Morris, of Indianapolis, has moved to Washington, D. C.

Dr. George H. Grant, of Richmond, health officer of Wayne County, is very ill with typhoid fever.

Dr. S. C. Markley, of Richmond, was elected city physician and police surgeon of Richmond, September 4.

Dr. Austin Funk, of New Albany, has been appointed on the staff of the United States Marine-Hospital at Cairo, Ill.

Dr. Charles A. Ross, of Leopold, has been appointed acting assistant-surgeon in the army, and has started for his post of duty in China.

Dr. William D. Schwartz, of Portland, has sailed for Europe. He intends to pursue his studies in the hospitals of London and Paris.

St. Margaret's Hospital, Hammond, has organized its staff as follows: Dr. Cyrus W. Campbell, president; Dr. James T. Clark, vice-president; Dr. H. Edgar Sharrer, secretary. The hospital will be ready to receive patients in a few days.

The Board of Health of Logansport announces that, in view of the existence of smallpox in the city, and of the order for compulsory vaccination recently promulgated by the board, it will vaccinate free of charge all school children whose parents are unable to pay for vaccination.

Marion has a strong anti-vaccination party, which has formed a society whose members have agreed to send their children to school in defiance of the compulsory vaccination orders, and if not allowed to enter the matter will be taken to the courts.

The new state law, which goes into effect this fall, provides that first-year students who do not possess a literary degree, a diploma from a high school, or a teacher's life certificate must pass an entrance examination before a representative of the State Board of Medical Registration, who must not be in any way connected with any medical college.

Dr. Joseph G. Rogers, superintendent of the Northern Insane Hospital, at Logansport, saved the state a large sum by preparing the plans for the two new buildings erected this summer and superintending their construction. The trustees have granted him a vote of thanks for an honorarium, and have increased it by sending a copy of the resolutions to the governor.

INDIAN TERRITORY.

Dr. Franklin M. Duckworth has been appointed pension examining-surgeon at Claramore in the Cherokee nation.

Dr. Charles F. McElraith, formerly of Enid, has been appointed superintendent of the Canadian County Board of Health vice Dr. William J. Muzzy, of El Reno, resigned.

IOWA.

Dr. Albert E. Rector, of Lake Park, has moved to Spirit Lake.

Dr. Caleb P. Soper, of Spirit Lake, has moved to Warrensburg, N. Y.

Dr. J. W. Cokenower, of Des Moines, has returned from his European trip.

Drs. Egerton J. and Nellie M. Unger, of Mount Union, have located permanently in Keokuk.

Dr. Benjamin F. Andrews has given up the practice of medicine in Oskaloosa, and will enter the missionary field.

KANSAS.

Drs. Willis H. and Ida A. Hall, formerly of Topeka, have opened offices at Rock.

Dr. William M. Arnold, of Larnech, has been appointed coroner of Pawnee county.

The Kansas Medical College, Topeka, opened September 11. The attendance promises to exceed that of any previous year.

Dr. A. W. Schockley, acting asst.-surgeon, U. S. A., son of Major W. B. Schockley, of the Soldiers' Home, Leavenworth, has been made superintendent in charge of inspectors of sanitary work at Havana.

KENTUCKY.

Dr. James T. Blackburn has been nominated trustee for the Twelfth ward, Louisville.

Dr. Theodore N. Wise, one of the most highly esteemed physicians and citizens of Covington, is critically ill at his home.

Dr. Abraham S. Stanley, late of the house staff of the Western Kentucky Hospital for the Insane, has decided to remain in Hopkinsville and go into private practice.

LOUISIANA.

Monroe has elected a new board of health, consisting of Drs. Charles W. Hilton, Addley H. Gladden, and M. A. McHenry.

A plan for a proposed isolation hospital, which is urgently needed at New Orleans, has been approved and the city council is to be asked to authorize its construction forthwith. The plan, which was prepared by Dr. Sidney L. Theard, secretary, and treasurer of the city board of health, contemplates a hospital on the pavilion plan.

Dr. Quitman Kohnke, president of the New Orleans Board of Health, presented at the September 10 meeting a map showing the location of the 467 dairies which do business in the city. He also commented upon the decreased mortality of the city and stated that the death-rate for August was lower than for any August in the preceding five years.

MAINE.

Dr. L. S. Purrington has opened an office in Gray.

Dr. N. E. Nichols will locate for practice in Jackman.

Dr. Augustus B. Drummond, of Bangor, has gone to Rockland, where he will locate for practice.

Dr. B. F. Peabody has purchased the practice of Dr. Erving A. Libby, of Rangeley, and will locate there.

The contract for the masonry of the new Sisters of Charity Hospital, Lewiston, has been awarded, the bid being $28,490. The wood construction of the building has been contracted for at $39,171.

MARYLAND.

Typhoid fever is unusually prevalent in Carroll County, especially near Westminster.

The death of Mr. Henry C. Hallowell, of Montgomery County, removes probably the foremost sanitarian outside of the profession. For sixteen years he held the position of president of the board of health of Olney district, and by his untiring devotion to its interests, wise foresight and courtesy in carrying out the decisions of the board, he not only assisted materially in keeping alive voluntary sanitary association, but made it respected, appreciated and obeyed, by the general public, without opposition.

Baltimore.

Dr. G. Milton Linthicum is visiting the Paris Exposition.

The will of Mayor A. Nusbaum bequeaths $100 to the Hebrew Hospital.

The Maryland Medical College opened September 17 with an introductory address by Prof. Richard L. McNeer.

For the week ended September 8, there were 75 deaths among children under 5 years of age. There were 23 deaths from cholera infantum, 14 from dysentery, 4 from typhoid fever, and 29 from consumption.

The drinking water used in the school is the subject of much discussion. Owing to the prevalence of typhoid fever, the health commissioner has warned the citizens to boil all drinking water, yet no precautions are taken in the public schools, where the children drink out of open buckets exposed at all times, using a common tin cup.

The surgeon-general of the Marine-Hospital Service has asked the health commissioner to secure the aid of the steamship companies in preventing the introduction of the bubonic plague, as has been done by the authorities of New York. Dr. Wyman desires the ship's surgeon to take the temperature and make examinations of the crew and steerage passengers twenty-four hours before the vessel reaches port, and keep a record of the same for the guidance of quarantine officers.

The health commissioner calls attention to the great prevalence of typhoid fever in Baltimore. In August, 1899, 74 cases were reported, with 25 deaths; in August 1900, 189 cases were reported, with 37 deaths. The increase in cases reported and the lessened death-rate are believed to be due to a more strict compliance by physicians with the law compelling the report of typhoid cases to the department. It is not thought that there was such a large increase of cases as is shown in the figures. Formerly it was considered that the disease was limited chiefly to elderly people; now many children are found to be suffering with it. The following figures show the mortality in Baltimore from typhoid fever in the last ten years. Total deaths, 1928; 1890, 247; 1891, 150; 1892, 193; 1893, 224; 1894, 222; 1895, 173; 1896, 188; 1897, 189; 1898, 189; 1899, 153.

MICHIGAN.

Dr. William M. Harvey, of Detroit, sailed for Europe, September 8. He will study in Berlin.

Petoskey has raised nearly $5000 for a hospital and expects to have the foundations laid before winter.

The state law may be tested in the case of Miss Heideman, of Calumet, who came from Finland four months ago, and claims to have a diploma in medicine from the University of Helsingfors. She has been practicing in Calumet, but has taken no examination on account of her ignorance of English.

The Bay City Board of Health, on September 7, adopted the following resolution: "Resolved, That the board of health does hereby most respectfully ask that the physicians of Bay City shall always inspect a case of contagious disease before asking the health officer to remove the sign or disinfect the house, and that the health officer, before removing the sign, ascertain whether the physician has carried out the import of this resolution." The necessity for this action is that frequently the attending physician in a contagious disease case will order the warning sign removed from the house before the danger period has passed.

MORTALITY FOR AUGUST.

There were 2954 deaths in Michigan reported to the department of state during August. This number corresponds to a death-rate of 14.5 per thousand, as compared with a rate of 12.4 for the preceding month, and a rate of 13.8 for August, 1899. The mortality of the State of Indiana for August was 14.3 per thousand, or practically the same as that of Michigan. The number of deaths returned for August is 455 more than for July. There were 811 deaths of infants under 1 year of age, an increase of 250 over July; 268 deaths of children aged 1 to 4 years inclusive; and 630 deaths of persons aged 65 years and over. Important causes of death were as follows: Pulmonary tuberculosis, 122; other forms of tuberculosis, 51; typhoid fever, 68; diphtheria and croup, 19; measles, 6; whooping cough 17; scarlet fever, 15; pneumonia, 80; diarrheal diseases of infants under five years, 586; cerebrospinal meningitis, 37; cancer, 121; accidents and violence, 187. As compared with the preceding month, a slight increase is noted in the number of deaths from diphtheria and croup, a considerable increase in the fatality of typhoid fever, and a large increase—308 deaths—in the mortality from diarrheal diseases of children. This latter increase is characteristic of the annual "slaughter of the innocents," chiefly from "cholera infantum," a type of disease which is entirely or largely preventable by proper sanitary and hygienic methods.

MINNESOTA.

County Physician Ancker has named Dr. James S. Gilfillan, of St. Paul, as assistant county physician.

Major Thomas C. Clark, M.D., of Stillwater, was married at Decorah, Iowa, to Miss Mary I. Breckenridge, on Sept. 11.

The foundations of Asbury Hospital, Minneapolis, will be completed by October 1, at a cost of $10,000, which is already in hand. The directors already have $25,000 of the $50,000 required to complete the building.

The Hospital Committee of the Board of Charities and Corrections has been notified that $23,000 of the $30,000 required have been raised toward the quarantine station at St. Louis Park, and the cottages for the Minneapolis City Hospital.

Dr. Gustav A. Renz, as president of the Ramsey County Medical Society, has filed charges against four physicians in St. Paul, that they advertise fictitious cures. The accused are cited to appear before the State Board of Medical Examiners, on October 11.

MISSOURI.

Dr. William E. Cass, of St. Louis, acting assistant-surgeon in the army, has been ordered to report for duty to the chief surgeon at San Francisco.

The board of managers of the State Insane Asylum at Nevada has re-elected Dr. Joseph F. Robinson superintendent of the asylum for four years.

Dr. Albert Steinrauf, of St. Charles, has been notified of his appointment as acting assistant-surgeon in the army, and has received orders to report at San Francisco for assignment to duty.

Dr. I. N. Love, of St. Louis, has removed to New York City to engage in the practice of his profession. He has accepted a position in the department of internal medicine and diagnosis in the Post-Graduate Medical School and Hospital. His address is Hotel Iroquois, 49 West Forty-fourth street.

The death-rate of Kansas City is increasing. In 1899 it was 10.9 per thousand, and in 1889, 13.6. During 1899 2662 deaths occurred, 1752 adults and 910 children. Of these 507 were under 1 year of age. Violence was the cause of 128 deaths. The maximum of deaths occurred in April, 313, and the minimum, 157, in November.

MONTANA.

Dr. William H. Campbell, of Livingston, has moved to Kalispell.

Dr. Josiah R. Hammond, of Butte, will return from Europe and resume practice early in October.

Dr. Benjamin C. Brooke, of Helena, was so unfortunate as to step into an open hatchway in Butte on August 30, while in attendance on the meeting of the Interstate Medical Association. He fell eight feet and broke three ribs.

NEBRASKA.

Dr. August F. Jonas, of Omaha, has returned recently from the International Medical Congress.

Dr. Fred W. Lester, who left David City for his old home in Illinois, has returned to David City and resumed practice.

Dr. Jay Ryan, a recent graduate of Creighton Medical College, has been appointed physician for the poor of Douglas County.

Dr. Victor H. Coffman, of Omaha, has been forced to spend some time in the mountains on account of illness. He has returned much improved.

The governor has been formally requested by the Omaha Medical Society to reappoint Dr. Benjamin F. Crummer, of Omaha, on the State Board of Health.

NEW JERSEY.

Dr. Grant Sparks has been elected physician to the Gloucester County Almshouse.

Dr. William S. Jones, of Camden, has been re-elected county physician for a term of three years.

Dr. Rolland Tomlinson, of Plainfield, [illegible] ated [illegible] practice with his father, Dr. T. H. Tomli

The budget for Atlantic City has been issued for the coming year, and among other items approved by the council are improvements for hospital, $10,000; sanitary improvements, $24,500.

The sanitary condition of Atlantic City at the present time is said to be bad, and this is especially due to the defective sewerage system and the lack of attention from the board of health.

NEW YORK.

Dr. C. C. Lytle has located for practice in Syracuse.

Dr. Richard Ellis, of Utica, has moved to New York and opened an office at 147 East Twenty-first street.

Dr. Edmund C. Body, city physician of Rochester, was married on September 4, to Miss Jessie Cameron Cogswell, also of Rochester.

Dr. Charles E. White, of Waterville, has moved to Rome, where, with his wife, who is also a physician, he will continue in practice.

Dr. J. D. Shipman, who, after his graduation, studied for a year in Germany, and then served for another year as house physician at St. Joseph's Hospital, Syracuse, has located at Amsterdam.

The health report of Rochester for August shows 220 deaths, 269 births and 111 marriages for the month. The death-rate was 15.94 per thousand, based on the census figures of 162,435. Of the decedents 54 were under 1 year of age; 14 between 1 and 5 years, and 82 over 60 years. The chief causes of death were: Contagious diseases, 25; cholera infantum, 22; apoplexy, 16; dysentery, 13; heart disease, 19; violence, 13. There were 17 more deaths than in August, 1899.

St. Peter's Hospital Staff, at Albany, was reorganized September 3, and the following physicians chosen: Consulting surgeon, Dr. Patrick J. Keegan; consulting physician, Dr. T. Kirkland Perry; attending physicians, Drs. Henry Hun, Howard Van Rensselaer, Andrew MacFarlane; attending surgeons, Drs. Samuel R. Morrow, William Hailes, Jr., John V. Hennessey; ophthalmic surgeons, Drs. George S. Munson, Theodore F. C. Van Allen; abdominal surgeon and gynecologist, Dr. John B. Harvie; nose and throat, Dr. Clement F. Theisen; obstetrician, Dr. John F. Reilly, of Rensselaer; pathologist, Dr. George Blumer; house staff; physician, Dr. Waldron A. Stearns; surgeon, Dr. W. Gansevoort Mack.

Buffalo.

Dr. Lucien Howe is in Europe.

Major Charles K. Winne has been detailed as post-surgeon at Fort Porter.

Dr. Roswell Park has been appointed medical director of the Pan-American Exposition. With the appointment of one so distinguished in his profession, this department of the exposition should respond to all demands made upon it.

The ordinance controlling the grain-drying industry has been passed by the city council. This will afford a great relief to the city because at times the stench arising from the wet, fermenting grain has been almost unendurable. Many cases of disease were caused and aggravated by this nuisance.

The Consumption Hospital, a building erected especially for tuberculous patients, which was recently totally destroyed by fire, is soon to be rebuilt. It will be situated on the outskirts of the city, on high and dry grounds, and being a department of the Erie County Hospital it has the advantage of a fine herd and many acres of good farm land. The hospital did and will do exceedingly good work in this field, because as a rule the patients coming to it are from the lower strata of life, very poor and ignorant. They, therefore, are not only benefited themselves by their hygienic environment and good treatment, but their relatives are protected by their separation from an aggravating source of infection.

Dr. Jacob Otto has been appointed assistant-superintendent of the Exhibit on Sanitation, with the collaboration of the health commission. He has addressed a circular letter to every health board in North and South America asking for its co-operation. The exhibits will be classed under two heads, the first, covering the proceedings pursued by the different boards of health in all matters pertaining to sanitation. This exhibit will be composed of the blank forms used by each board of health and of photographs of their public works devoted to sanitation, and of models of special features in municipal sanitation used in chemical and bacteriological work and disinfection. Models will be presented graphically illustrating the contamination of wells, practical tenement houses in comparison with insanitary rookeries. The second section will show the sanitary appliances used in disinfection, ventilation and heating, and will include models of plants in use by municipalities for supplying water, for the disposal of sewage, garbage, etc.

New York City.

Dr. Lucy M. Hall-Brown, of Brooklyn, has returned after a two-months' trip to Europe.

Dr. Henry E. Hale, Jr., was married September 12, to Miss Frances Hibbard Ward, of Chicago.

Dr. Charles F. Meinhardt, of St. Mark's Hospital, is spending his vacation in Duluth, Minn.

Dr. George F. Shrady has returned after a short trip to Europe. While there he went to Glasgow to look over the plague situation.

One of the New York hospitals has in operation a camera which records minutely, after the manner of a biograph, the actions of patients. These are reproduced on a screen, and physicians and students thereby enabled to study closely the manifestations of such diseases as locomotor ataxia, etc.

Michael C. Murphy, president of the health department, has given out plans for the new bacteriological laboratory to be constructed especially for the study of the bubonic plague germs. It will be erected near the Willard Parker Hospital, on East Sixteenth street, will be built of steel, with asbestos walls, and will have neither chimney nor windows.

The death is announced of Samuel Bradhurst Schieffelin at his home in New York City, aged 89 years. On the retirement of his father from business in 1849, Mr. Schieffelin and his brother managed the extensive drug business of Schieffelin & Co. He remained at the head of the company until 1865, when he was succeeded by his son. Since his retirement, he devoted himself to historical and religious study and writing.

OHIO.

The new pathological laboratory at Charity Hospital, Cleveland, is now completed and ready for opening.

Dr. James E. Murray, of Middletown, has disposed of his practice to Dr. L. S. Krauss, of West Carrollton.

The fall term of the Ohio Medical College, and Starling Medical College, at Columbus, opened September 12.

Dr. Albert F. Shiebley, of Glandorf, who has been studying in Germany for several months, has returned and will locate in Ottawa.

Dr. B. P. Hall, of Richwood, has been awarded the care of the sick and the furnishing of medicines to the poor of Claiborne township.

Dr. George W. Crile, of Cleveland, has been appointed to the chair of clinical surgery in the medical department of Western Reserve University.

The first fine under the Love medical law was imposed in Fulton county, when Dr. Pixley, a physician from Michigan, was arrested and fined $27 and costs.

The first examination under the Love medical law was held at Columbus, by the State Board of Medical Registration and Examination, September 9, 10 and 11. Nine applicants, all medical graduates, took the examination.

PENNSYLVANIA.

The school board of Caernarvon has instituted the use of individual drinking cups for its school children.

Dr. Robert W. Brace, of Blackwood, has been appointed resident physician at the hospital in Westport, Conn.

A mild epidemic of diphtheria now prevails in Carlisle. Fourteen cases have been quarantined by the board of health and four new cases have appeared.

Dr. Thomas S. Anderson and wife, of Carnegie, will soon leave for a six-months' sojourn in Europe. On their return they expect to locate in East End, Pittsburg.

Anthrax has attacked the herd of cattle belonging to William J. Irvin at Centreton, near Woodstown, and 5 out of 10 cattle have died. The state veterinarian now has matters in charge, and is affording protection.

The water board of the city council of Reading, in its recent report, recommends filtration of the water-supply from Antietam dam. On account of vegetable growth this source of water-supply is frequently rendered useless for weeks at a time.

The business men of Erie have demanded of the board of health and city council that a municipal hospital be built forthwith. There are now ten cases of smallpox in the city, and no efforts should be spared to limit and stamp out the disease.

Compulsory Education and Vaccination in Bradford County.—On September 3, Judge Fanning, of the court of quarter sessions of Towanda, Bradford County, filed an opinion in the case of the Commonwealth vs. E. L. Smith, in which the compulsory vaccination and the compulsory education laws were brought into question. The case was one in which Smith, who is a christian scientist, declined to have his son vaccinated and the boy was refused admission to the public schools. He subsequently received instruction at his home from his mother. Smith was fined $2 for non-attendance at school. The judge, in his ruling, stated: "We must conclude from the foregoing that the compulsory education act by its terms did not make it obligatory upon the defendant to obtain a certificate of vaccination. His sole duty prescribed by it was to send his son to school. He did this. The teacher refused the son admission simply because he did not present a certificate. There is nothing in this statute making vaccination mandatory in any case. Neither does it require the child to produce a certificate that it has been successfuly vaccinated or had smallpox. In order to sustain this judgment we must say that the defendant was obliged by the terms of the statute to procure and his son to present a certificate. We can not say this. The defendant made a clear answer to the case of the Commonwealth when he showed that he had sent his son to school until he was denied admission by the teacher. This is a question of the extent of the police powers of the legislature. Perhaps a law making vaccination obligatory in all cases except where the child has had smallpox would be a valid exercise of that power. This is unnecessary to decide. For so far the legislature has not expressly enacted such a law, and we do not feel disposed to hold that it has done so implicitly in order to sustain this judgment."

Philadelphia.

Dr. Andrew J. Downes has returned from Europe..

Dr. W. Barton Hopkins is spending a vacation at Newport.

Dr. E. E. Montgomery has returned from his European trip.

Dr. James M. Anders has returned from his visit to Dr. L. Webster Fox at Kennebunk, Me.

A bequest of $10,000 has been made to the Pennsylvania Hospital by Howard Roberts, who recently died in Paris.

The Home for the Homeless, at 4102 Ogden street, will hereafter be under the management of Dr. Rebecca Moore, assisted by a board of advisers.

Magistrate Kochersperger a few days ago fined a wagon-driver $5 for delaying the ambulance of the German Hospital while it was making a call to receive a patient.

The board of health censured an eclectic physician for not reporting a death from diphtheria promptly, and for allowing the body of the patient to remain near an open window for a day after death.

The Sanatorium Association has completed its twenty-fourth year, and the results show the largest increase over any previous year. The admissions for 73 working days were 180,670 adults and children, comprising 25,655 adults, 20,516 infants, 134.499 children over 2 years of age. Of bathers there were 23,265 boys, 25,591 girls and 4516 infants.

The Jewish Maternity Association has asked an amendment to its charter, and within a short time will make an addition to its equipment by erecting a gynecological ward and operating room. A benefit concert will be given at the Academy of Music, the proceeds of which will be given to the home.

TENNESSEE.

The City Hospital at North Knoxville is nearly completed. It is expected that it will be furnished and equipped to receive patients by January 1.

The new building of the Tennessee Medical College, at Knoxville, will be ready for occupancy before the opening of the college term in October.

Dr. D. M. Saunders, of Woodstock, has been elected superintendent of the Shelby County Emergency Hospital at Memphis.

The Memphis Board of Health has been notified by several southern cities that if the Memphis city council passes the amendment to the health ordinance offered at a recent meeting, which will require that the physicians of Memphis report all of their cases of tuberculosis and typhoid fever, they will follow suit and adopt a similar ordinance.

TEXAS.

Mercy Hospital has been incorporated at Laredo, without capital stock, but with property valued at $6,000.

Dr. E. E. Mansfield, of Wilmer, has been assigned to the Twenty-fifth U. S. Infantry as assistant-surgeon, and has left for San Antonio to join his regiment.

Galveston.

Dr. Hamilton A. West, whose death was announced by the Associated Press as having occurred in the recent tornado, has asked The Journal to state that he and his family are safe and well. Dr. West is actively at work with the Board of Health restoring order from chaos.

Dr. C. P. Wertenbaker, United States Marine-Hospital Service, stationed at New Orleans, has been ordered to Galveston. His instructions are to make an immediate investigation and estimate of the damage done, and the general condition of the inhabitants, and to keep the authorities in Washington in close touch with the situation.

The heroism of Dr. I. M. Cline, United States Weather Observer at Galveston, a member of the Texas State Medical Association, stands out brightly among the many heroic deeds recorded there. At noon he sent out warnings that a disastrous storm was imminent. Three hours later, realizing that an unparalleled storm was approaching, he went through the southern part of the city imploring the people to fly to the center of the island. As the telephone and telegraph systems were then wrecked, he made his way to the telephone station at the bridge west of the city and sent an appeal for aid, just before the cable parted. On his return, after this duty had been performed, he found his house destroyed and his wife and one child dead.

WASHINGTON.

The Deaconess Home at Spokane has let a contract for a $1,000 addition to its main building. This will increase the capacity of the hospital by six beds.

The City Council of Yakima has passed an anti-expectoration ordinance at the instigation of the State Medical Society. A second ordinance prohibits the issuance of burial permits without a certificate of death from a reputable medical practitioner.

WISCONSIN.

Dr. F. W. Watson has succeeded Dr. Timothy L. Harrington in his practice at Antigo.

Dr. Timothy L. Harrington, after five years' practice in Antigo, has moved to Milwaukee.

Dr. Frank Fordyce Newell, of Burlington, was married on September 3 to Miss Marie R. U. Young, at her residence in Chicago.

The supervisors of Milwaukee county [illegible] riat- $100,000 for improvements and additions [illegible] pital at Wauwatosa.

The hospital which the Lutheran synod is erecting at La Crosse, will soon be completed. It will cost in the neighborhood of $60,000.

Dr. Ferdinand M. Schulz, health commissioner of Milwaukee, recommends in his annual report the closing of all wells, the medical control of marriage as a means of lessening hereditary diseases, and the examination of school teachers for tuberculosis. The death-rate of the city was 13.48 per thousand, a little higher than that of the previous year. Of the 3843 deaths, 2065 were males and 1778 females. The deaths under 5 years of age numbered 1541 or 40.1 per cent. of the total mortality.

CANADA.

Whooping-Cough is epidemic at Ottawa.

The profession in British Columbia is contemplating the formation of a provincial medical society.

Several deaths among children in Toronto have been traced to eating ice-cream which had been re-frozen.

Dr. Charles O'Reilly, superintendent of the Toronto General Hospital, has just returned from an extended inspection trip of the hospitals of Winnipeg, St. Paul, Minneapolis, Milwaukee, Chicago and Detroit.

Dr. Lang, of Glasgow, the new professor of chemistry at Toronto University, has been busily engaged re-organizing that department. Dr. W. Lash Miller has been promoted to the position of associate professor of physical chemistry.

At the instance of the Toronto medical health officer, Professor Shuttleworth has made an analysis and inspected the reservoir. As a result he has advised that the city reservoir be immediately cleaned and newly cemented.

An arrangement has been made between the British and United States governments whereby a Marine-Hospital physician will henceforth examine all immigrants leaving the port of Liverpool for Canada. His services will be supplemented by the services of a Canadian physician to be appointed by the railway and steamship companies, with headquarters at Liverpool. Last week three emigrants with favus were refused transit from Montreal to New York by the American inspector.

The toast to the American Medical Association, at the banquet of the Canadian Medical Association, was received with gratifying enthusiasm. Dr. Frederick C. Shattuck, of Boston, responded in a clever and witty speech, saying that if the United States did not soon annex Canada, he hoped that Canada would soon annex the United States. The latter met with a happy approval; for, of course, there is no annexation sentiment in Canada in the former direction.

MARINE-HOSPITAL NOTES.

THE STATUS OF BUBONIC PLAGUE.

With the exception of India, where bubonic plague is prevalent in epidemic form, Rio Janeiro, Brazil, is probably the worst infected place in the world at the present time. Weekly reports to the surgeon-general of the Marine-Hospital Service from the acting asst.-surgeon located in that city show that there are under treatment in hospital between ninety and one-hundred cases, and that from three to five new cases occur each week. Persistent scientific disinfection and quarantine have stamped out the disease in all of the principal places where it has appeared within the last year or two, but constant vigilance is necessary to prevent its introduction and spread in all seaport towns. The viability of the plague bacillus is its chief danger. Epidemics are stamped out, but occasional cases continue to appear and are transported from one place to another, as is evidenced by the recent appearance of plague on a ship in the harbor of Hamburg, also a similar instance on board ship in the harbor of London. Plague was also carried from Syros Island to Constantinople within the past month. The present outbreak in Glasgow, while not yet traced, gives force to the argument that constant vigilance is necessary on the part of all seacoast cities, and that the danger is not past because the epidemic in any particular place has been suppressed.

INOCULATION AGAINST TYPHOID.

In a brief report to the surgeon-general, Dr. Geddings, acting director, hygienic laboratory, M.-H. S., summarizes the status of anti-typhoid inoculation as follows: In an infectious disease so widespread as typhoid fever it is perfectly natural that, since the discovery of its specific organism, efforts should have been made by bacteriologists looking to a means of preventing the disease, or of curing it when established, by means of serum therapy, or by affording an efficient protection against it by means of a "vaccination" such as has been practiced with success in the case of plague by the Haffkine prophylactic. Attention was invited to the subject in 1894, when Hughes and Carter reported favorable results in the treatment of two cases of typhoid fever with the blood-serum of a convalescent. These were followed by reports of a similar nature from Girard, Legrain, Sylvestri, Von Jaksch, Klemperer, Pollak, Weisbecker, Chantemesse and others. All of these observers had used either the serum of convalescents or the blister fluid of typhoid patients until the experiments of Chantemesse, who proceeded in the regular way by immunizing a horse by killed cultures of the typhoid bacillus and using its serum as a remedial agent. Lyonnette brought a horse up to a point of immunity where his serum had an agglutinating power of 1:33,000. Naturally the subject attracted attention in the Hygienic Laboratory of the Marine-Hospital Service and a series of experiments was commenced by P. A. Surgeon E. K. Sprague, then in temporary charge of the laboratory. Beginning in 1897, and continuing more or less regularly until December, 1898, a horse was treated, first with increasing doses of killed cultures of the typhoid bacillus, and later with intravenous injections of a suspension of live cultures of the same bacillus. In December, 1898, the serum of this horse had reached an agglutinating power of 1:250,000. In April, 1899, the agglutinating power of the serum on the typhoid bacillus had risen to 1:500,000. There has been no opportunity of using this serum upon actual cases of typhoid fever, but Sprague, experimenting with guinea-pigs, in two series of experiments, succeeded in preserving animals to whom a lethal dose of the typhoid bacillus had been administered by the use of the serum, while the controls in every case died. The above has been summarized from a very full report by P. A. Surgeon E. K. Sprague. The subject of anti-typhoid inoculation, from this time on, while receiving more or less desultory attention, was only prominently brought to the front again by English reports of inoculation of British troops destined for service in the Indian Empire, where favorable results seem to have been reached. The latest statistics on the subject come from South Africa, favorable conditions having arisen during the siege of Ladysmith, in the Transvaal, for observation on the subject. The following, from the *Journal of Tropical Medicine*, July, 1900, has important bearing on the subject: "Important statistics have at last been made public concerning the probable effects of inoculation against typhoid. The figures relating to the results have been communicated by Dr. A. E. Wright, professor of pathology in the Army Medical School, Netley, and they are founded on the experience gained in Ladysmith during the siege. The number of officers and men under observation numbered 12,234; of these 1705 had been inoculated, leaving 10,529 non-inoculated or non-protected. During the siege 1489 cases of typhoid fever occurred among the non-inoculated and 35 among the inoculated. From these figures it is seen that 1 in 7.07 of the non-inoculated contracted typhoid, whilst only 1 in 48.7 of the inoculated were attacked. The lessened mortality also among the inoculated is marked; for of the non-inoculated persons attacked 329, or 1 in 32, died; while among the protected 8 deaths only occurred, or 1 in 213. Professor Wright remarks that in the returns the 'inoculated' are not definitely specified; inoculations being made to include, in all probability, persons treated by either the anti-typhoid serum or the sterilized vaccine culture, *or even vaccination against smallpox.* We await with interest a full investigation and report on this most important and interesting question, and it is to be hoped that Professor Wright's treatment may be proved to be a real protection."

OTTAWA LETTER.

Canadian Medical Association.

The thirty-third annual meeting of the Canadian Medical Association was held in the Academic Hall of the University of Ottawa, Ottawa, on Sept. 12-14, 1900, under the presidency of Dr. R. W. Powell, of Ottawa, Dr. F. N. G. Starr, of Toronto, acting as secretary.

ELIMINATIVE AND ANTISEPTIC TREATMENT OF TYPHOID FEVER.

Dr. W. B. Thistle, of Toronto University, in contributing this paper, stated that it was now seven years since he introduced this plan of treatment of typhoid fever to the profession. He had never held to the opinion that the eliminative and antiseptic plan could rid such organs as the liver and spleen of the bacilli lodged in them. He held to the opinion that the draining of the intestinal walls following on the action of a purgative such as calomel and mag. sulph. would tend to get rid of some of these bacilli and their toxins in the intestinal walls, but did not claim to effect their exit from the liver, etc. In many instances he thought the treatment had been imperfectly applied without a clear conception of the underlying principle. Under this plan, Dr. Thistle has never had a fatal case of hemorrhage, what hemorrhage occurred having been always very slight. He has also had few perforations. In Toronto this plan of treatment is universally adopted. Statistics at the Toronto General Hospital show, that from 1893 until the present time, there have been 823 cases in that institution with 56 deaths—a mortality of 6.5 per cent. under this plan of treatment.

In discussing the paper, Dr. McPhedran stated that he had watched Dr. Thistle's work from the time of the appearance of his first paper on the subject, but could not agree with all his conclusions. He did not think that it lessened diarrhea, tympanites, fever or delirium. He considered that Dr. Thistle was harboring the idea that purgatives in typhoid was a new discovery with him; this was not so. Twenty-five years ago he gave these for the first ten days at least. In addition to this he used to give carbolic acid and iodin, and in a certain class of cases, he thought he had the exact treatment. Another class would then come along, in which that treatment had no effect whatever. He considered that the general toxemia that existed could not be eliminated through the bowel. It had to be done through the kidneys and skin.

SARCOMA OF THE RIGHT NASAL FOSSA WITH ORBITAL CELLULITIS.

This paper and case was presented by Dr. Perry G. Goldsmith, of Belleville, Ont. The patient was a man of 38 years, a farmer, with an unimportant family and personal history. He consulted the Doctor on August 4, with severe frontal headache. Growths and some bone were removed from the nose. After this the swelling and pain in the eye rapidly increased, so that it was seen to project far forward, downward and outward. The growths in the nasal fossa were curetted and sent to Professor Anderson of the Trinity Medical College Pathological Laboratory, who pronounced them of sarcomatous nature, of small round-cell variety, with the walls of the blood-vessels thin and poorly developed. The discharge from the nostril was of an odor similar to that emanating from cancer of the uterus. Up to ten years ago Bosworth had collected forty of these cases.

Dr. R. A. Reeve, Toronto, stated that a number of years ago he had presented a paper before the Association on the same subject. He directed attention to the importance of examining the nasopharynx in diseases of the orbit. He instanced a similar case to Dr. Goldsmith's. In his case there was little pain, but an examination of the nose revealed the tumor.

PRESIDENT'S ADDRESS.

Dr. R. W. Powell delivered the annual presidential address. He recited a few reminiscences when on former occasions the Canadian Medical Association had met in the Capital City in 1871, 1881, 1889 and 1893. Reference was made to the South African war in order to show the unsatisfactory condition of affairs which permitted other colonial surgeons practicing their profession in that land without hindrance, whilst Canadians were debarred from the same privilege. An earnest and united effort on the part of the profession throughout the entire Dominion of Canada in an endeavor to bring about interprovincial registration, would facilitate matters in the direction of securing these privileges for the Canadian profession in other parts of the British Empire. The hackneyed subject of tuberculosis was lightly touched on; whilst a very important matter relating to the profession, that of a Medical Defense Association, was dealt with at considerable length. Dr. Powell favored the formation of such Association, and later on in the proceedings nominated a committee to look into the question and report on the advisability and practicability of forming a Dominion association of this character.

SOME EXPERIENCES IN THE SOUTH AFRICAN WAR.

Dr. G. S. Ryerson dealt first with the experience gained of modern bullets. The very latest returns show that 936 officers and 11,701 non-commissioned officers and men had been wounded, of whom only 732 have died of wounds received in action, which is ascribed to the aseptic character of the bullet and the prompt attention and antiseptic treatment. Dr. Ryerson then dealt with these wounds, which is familiar to all. Referring to poisoned bullets being used, this was not the truth, as the tarnish or verdigris probably accumulated in transit through the barrel. He also doubted the fact of explosive bullets being used. The Boers made use of thousands of the Martini-Henry, a heavy bullet, which caused great destruction of soft parts, necessitating amputation. There were few amputations in this war; and quoted Kendal Franks, who performed 20 amputations in 2000 cases. Whilst abdominal section in wounds of the abdomen was mainly inadvisable, he saw one case where the results were excellent. He spoke highly of the magnificent work of the R. A. M. C.

Dr. Roddick spoke of the sacrifices of Dr. Ryerson in proceeding to South Africa at his own expense to carry out the work of the Red Cross Association. While in England recently, he stated, he made it his special business to inquire of returning Canadian soldiers as to the hospital management in South Africa, and although he had spoken to many of these, he had failed completely to find a single Canadian who had anything but praise for the hospital arrangements in that country.

OUR RACE AND CONSUMPTION.

Sir James Grant, Ottawa, read a paper on "Our Race and Consumption," which will appear soon in The Journal.

RECOGNITION AND MANAGEMENT OF TABES DORSALIS.

Dr. Allen McLane Hamilton presented a paper on this subject. As an etiological factor, syphilis was not referred to by the early writers on this disease. While some would attempt to divide the symptoms of the disease into the leg and eye types, the writer would consider that to be unwarranted. He considered there was a close resemblance or rather relationship between the different forms of cerebrospinal sclerosis. There was no disease of the nervous system which had drawn forth so many plans of treatment; and little or no good had resulted from any one thing. Most tabetics are favorable subjects for expectant attention; and many derive temporary benefit from some new drug. Looking back over a number of years, he finds that most good has been done where little or no medicine had been given. He has found rest by suspension and persistent cauterization of the back good treatment. In the opinion of the writer, syphilis can not be traced in more than 50 per cent. of the cases. For the arthropathies of the great joints there is little to be done. Perforating ulcer is a rare feature of locomotor ataxia, and most obstinately resists treatment. He has seen three cases of this unusual condition in ataxics; and the ulcer rarely exceeds two to three centimeters in diameter. One authority quotes five cases cured by nerve stretching.

THE PHYSICIAN'S "VASTER EMPIRE."

Dr. John Hunter, of Toronto, dealt with the questions of sanitary science, education, social purity and medical missions. As regards sanitary [illegible] the pu[illegible] of the p was a plea for the broader and freer attainment of principles of sanitary science and their application in the building and construction of our homes, schools, churches, etc. No dwelling-house should be constructed except under the supervision of an architect and a physician versed in sanitary science. Architects have improved wonderfully in the past ten years. Another important question is our educational system—the mental and physical health and development of our school children. The best way to secure physical vigor and high mentality is surely within the province of the physician to grapple with and study. In all forms of social purity and impurity, physicians should speak *ex cathedra* against every form of vice and immorality. The boys and girls of the family should be enlightened as to their sexual proclivities at proper periods, by the fathers and mothers, respectively. In medical missions he referred to the vast field for medical missionary work in foreign countries.

ADDRESS IN SURGERY.

MR. EDMUND OWEN took for his subject, "Tuberculous Lesions From a Clinical Point of View." He stated that he would deal with tuberculous lesions as the surgeon meets them day by day in the hospital ward, in private practice and in the operating theater. He considered the pathologist's thought to be only of the dead tissue. The surgeon sees the human tree during its life, but rarely follows it after death. The student does clinical and pathological work at different times, and he is enabled to follow the case straight from the ward to the laboratory. Study of the fresh specimen is best; for the specimen taken from formalin is no more like the condition than canned salmon is like fresh-run fish. He would not hinder experimental research work; it is absolutely essential. The life of a man is of more value than a sparrow or many guinea-pigs. It would be almost impossible to overestimate the direct value of experimental laboratory work. Strumous and scrofulous are terms devoid of meaning, and we now call tubercle by its proper name. There are three great factors in connection with tuberculosis with which the public must be made acquainted: 1. The disease is communicable, but they must be allowed a little time before they accept this statement and fact. 2. The disease is preventable; this follows almost as a corollary to the first statement. 3. The disease is curable. Years ago the subject of tuberculosis was regarded as well nigh hopeless. Tuberculosis is not necessarily of the intractable nature that it was formerly considered to be. Tuberculous lesions are exactly what they used to be; and Mr. Owen has worked at the largest children's hospital in London, England, for over a quarter of a century. We now take a much more hopeful view of these lesions. One rarely hears now of *vis medicatrix naturæ;* surgery has rendered it superfluous. All have noticed old cases of long-standing hip-joint disease where, in time, the boy actually grows out of his trouble. This is a popular superstition, but like most erratic beliefs, it is founded on a stratum of truth. In children these chronic diseases are always tuberculous. Where chronic abscesses occur it will not do to open and drain, but they must be scraped out, the unhealthy lining destroyed. In the treatment of these diseases the learned surgeon stated that he had failed to find any value whatever in iodoform. It is an irritant and a poison; and it is apt to be septic, as germs can grow on it. Mr. Owen condemned the forcible correction of spinal deformities, and considers that this deformity does not lend itself to operative treatment. There may, perhaps, be a small class of cases where it may eventually be found applicable, as where bone or organized inflammatory deposits press on the cord so that the patient has lost movement of the lower extremities. He considers that the plaster-of-paris jacket must be held responsible for much of the deformity of Pott's disease. He considers that the proper treatment of these cases is rest in the horizontal position, with plenty of good fresh air and sunlight. At the conclusion of his address he was accorded the hearty thanks of the association, on motion by Professor Shepherd, of McGill, seconded by Professor Cameron, of Toronto University.

DR. A. PRIMROSE, of Toronto, described Kocher's method of dealing with tuberculous knee-joint, and recited the histories of a few cases, in which he had obtained excellent results.

RECENT PATHOLOGIC STUDIES OF THE BLOOD.

DR. L. H. WARNER, Brooklyn, premises his statements by asserting that there is a necessity for experiments for the progress of pathology. His experimental researches were directed along three lines of inquiry, viz., experiments, observation and individual observation at clinics in hospitals. The examination of the blood in most case is of more importance than the examination of the urine. Dr. Warner gave the formula of a new staining solution which he had found very practicable: The blood specimen should be prepared in the regular manner. The slides are heated in a hot oven to 98 degrees. Immerse it for one minute in a 1 per cent. aqueous solution of methylene blue, washing in water, then in 1 per cent. alcoholic solution of eosin, washing again with water, and then in a 1 per cent. solution of bismarck brown.

SOME EXPERIENCES IN THE TREATMENT OF HERNIA.

DR. F. J. SHEPHERD, Montreal, said that it is now some twenty years since surgeons began to do these operations by the open method. Older methods in vogue before that date were touched upon and described. He spoke of a large hernia where the man could not put on his trousers. The methods of operation are almost as numerous as surgeons, but there are certain general principles underlying all operations: 1, the necessity for excision or obliteration of the sac; 2, closure of canal, and 3, union by first intention. Some also hold that alteration in the direction of the canal is necessary. Bassini's is the operation performed by Dr. Shepherd, although not always successful. He has used all kinds of sutures. Absorbable sutures are the best and, if antiseptic, are to be preferred. A suture that will last for three weeks is all that is wanted. He has used chromicized catgut; he has used it now for some time. He never washes out the wound, and thinks it better to dissect out the sac with the knife than to tear it with the fingers. He never uses a drain. For the last two years he has used rubber gloves in all his surgical work on the abdomen, and he considers his results have been better since he used them. In these operations the mortality is practically nil. Operations on children are now our most successful cases. Formerly they were not advised except in strangulated cases.

In discussing this paper and the cases recited, Dr. A. Lapthorn Smith stated that his experience lay mostly in ventral and umbilical herniæ, some of them being so large as to require twenty stitches. During the past two years he has abandoned silk and resorted to chromicized catgut, which he always prepares himself.

Dr. Shepherd, in replying, said if there was a little oozing in the wound he introduces between the edges of the wound a probe, and lets out the accumulated serum, and he finds that this is quite efficacious, as by this method he minimizes the chance of any germs entering.

SYPHILITIC GUMMATA OF THE SPINAL CORD SUCCESSFULLY TREATED BY ENORMOUS DOSES OF IODID OF POTASH.

DR. F. W. CAMPBELL, of Montreal, said the patient was a highly neurotic individual, and some time before had suffered from insomnia of an aggravated character. Retention of urine and loss of power in the lower limbs were noted. The patellar reflex was about normal. The loss of power in the lower limbs was absolute. The pulse varied from 80 to 96; the temperature never above 99. The stomach remained in fairly good condition all the time. A consultant from New York was brought in and a diagnosis was established of tumor of the spinal cord, situated about the first lumbar vertebra, which might be sarcomatous or syphilitic. The advice of the consultant was to give 500 grains of iodid of potash per day, at first commencing with a dram three times a day. Dr. Campbell recited the daily history of the patient while getting under the large dose and its gradual withdrawal. The patient is alive to-day and in good health, having recovered complete control of his lower extremities.

he was able to get perfect cleanliness, and both wounds healed by first intention.

DILATATION AND PROLAPSE OF THE STOMACH.

Professor McPhedran, of Toronto University, dealt principally with prolapse. This condition rarely occurs alone, but is associated with prolapse of other abdominal organs. There is generally present as well some degree of dilatation; and the abdomen may be prominent or flat, or even retracted. He recited the case of a man aged 51 years, a manufacturer, who had been ailing for two or three years. The stomach was below the umbilicus. He was directed to massage the abdomen very thoroughly and to practice abdominal gymnastics. Through this treatment, combined with dietetics, he has been restored to health and is able to resume business. Another case was of a woman, aged 35 years, who had been the subject of recurrent attacks of vomiting for two years; massage and abdominal gymnastics ordered with satisfactory results. In concluding, Dr. McPhedran spoke of the benefits of a change of scene in treating these cases.

Dr. B. E. McKenzie read a paper on "Physical Training; Its Range and Usefulness in Therapeutics." It embraced the results of his observations for thirteen years past, and was ample justification of the benefits derived from gymnastics in the correction of lateral curvature, clubfoot, etc. He had found physical training also especially valuable in hysteria and chorea.

INTERPROVINCIAL REGISTRATION.

Dr. T. G. Roddick read a report of the committee having this matter in hand. A new feature was that allowing of representation on the proposed Dominion Council of homeopaths, as, according to the law of Ontario, these had their vested rights, and so must have similar interest in any Dominion Council. The homeopaths then will be allowed three representatives, which will be equivalent to the representation from any one province of the Dominion. Their term of office will be four years. This will not, however, be inserted in the bill as such, but will appear under "any other school of medicine having legal recognition throughout Canada," as the British Medical Council would not recognize any such body. Dr. Roddick stated that the bill would be introduced at the next session of parliament, and that the respective members of the committee must bestir themselves before their respective provincial parliaments, as these must sanction the measure before it could be finally acted upon by the Dominion parliament.

CEREBRAL ABSCESS.

Dr. James Stewart reported two interesting cases of abscess of the brain, situated in the temporosphenoidal lobe, and referred to the unusual existing aphasia, which was present in both of these cases, viz., simple inability to name objects. The first case occurred in a young man of 22 years, who had otitis media following an attack of influenza. Some six weeks afterward an abscess formed. The abscess was diagnosed as confined to this area simply on account of the peculiar aphasia, the simple inability to give the name of a pen when that object was presented to him. The patient was operated on by Professor Bell, who secured two ounces of pus. Meningitis, however, set in and the patient succumbed. The second case was a girl of 21 or 22 years. She had had ear trouble for a great many years, with very severe pain at times. She, too, had difficulty in naming objects, and she could not name any object whatever finally. She died suddenly a few hours before the operation was to be performed. On post-mortem two abscesses were found, one skirting the upper border of the lobe and the other about the center of its substance.

GANGRENE OF THE LEG FOLLOWING TYPHOID FEVER.

Dr. H. H. Chown, Winnipeg, reported two cases of gangrene following an attack of typhoid fever, which had recently come under his observation. In the first case the patient had the classical symptoms of typhoid. Great pain set in in the calf of the leg, with collapse, while the limb was cold and bloodless. Cutaneous sensibility was lost over the leg. The third day after the complication set in the part involved included the lower third of the leg on inner side and lower half on outer. Operation was performed at upper and middle third of femur. Patient stood the operation well. The temperature before the operation was 102.6; pulse, 120. On the following day the temperature was normal and the pulse 110. On the tenth day the flaps were united. There was a rise of temperature a few days later—a relapse, with hypostatic congestion of the lungs. On the fifth day hemorrhage of the bowels. The patient is now a picture of health, weighing 200 pounds. The second was a somewhat similar case, in which the blood reacted early and promptly to the Widal test. The gangrene began in the first case on the eleventh day of the disease; in the second, on the ninth. Keen reports gangrene on the fourteenth day. The gangrene in the second case extended to the upper and middle third of leg. The leg was amputated and prompt union took place throughout.

Dr. R. B. Nevitt, Toronto, mentioned a similar case coming under his observation during the past summer. Here gangrene occurred about the third week of the fever; patient was seen about a week or ten days afterward. Amputation was performed through the middle third of the femur. He also referred to a case of gangrene of the arm following an attack of pneumonia, recently observed by him.

NOTES ON ATROPIN.

Dr. R. D. Rudolf, Toronto, read a paper with the above title, illustrating by means of a chart the action of the drug on animals and inferences drawn therefrom of its therapeutic uses. He finds that the drug directly stimulates the heart, and thus the blood-pressure is markedly raised. He considered that the maximum single dose, as laid down by Witherstine, of 1/20 of a grain is too large, unless used as an antidote; we ought never to give more than 1/100 of a grain of atropin sulphate at one time, except in emergencies. He also referred to its action in catarrhal pneumonias of children, and its employment before anesthesia to ward off danger.

Dr. A. D. Blackader considered, however, that strychnin, and not atropin, was the most powerful heart tonic we possessed. He thought that late experiments would throw doubt upon atropin being a direct stimulant to the heart muscle; and he thought it questionable to administer a drug, when we wanted to stimulate the heart's action, that would paralyze nerve endings.

LANTERN SLIDE DEMONSTRATION OF SKIN DISEASES.

Dr. George H. Fox, New York, conducted this demonstration, which the members of the association appreciated most highly. The great majority of the skin lesions shown were of syphilitic origin and, as they appeared on the canvas, Dr. Fox described the histories of the cases. One in particular attracted attention, from the disfigurement of the nose and face—a huge mass of excrescences, which Dr. Fox was able to get rid of in the course of two or three months, leaving only a slight superficial scar. He laid down a timely word of caution in treating these conditions: that when the patient was run down and emaciated through large doses of mercury or iodid of potash, not to keep on pushing these drugs, but desist for a period and endeavor to build up the patient's general condition. Then return to the specific treatment, and the results would be found to be more material.

Dr. F. J. Shepherd showed a case, a boy of 16, who, at the age of 6, sustained a severe cutting of the nerves of the brachial plexus, below the cords of the plexus. At that time, ten years ago, Dr. Shepherd dissected out each nerve and united their respective ends by suture. All did well, with the exception of the musculospiral, and as a consequence the lad has very little control over the extensors of the fore-arm.

Dr. George H. Burnham's method of treating syphilitic and other diseases of the eye is described in the title of his paper, "The Successful Treatment of Two Important Cases of Disease of the Eyes by the Combined Methods of Mercury and Iodid of Potash Internally and Pilocarpin Hypodermically." No such result follows in other plans of treatment, and with this a permanent curative result is obtained. The treatment has a wide application.

MENTAL SANITATION.

DR. R. W. BRUCE SMITH, physician to the Brockville Asylum for the Insane, contributed a paper with the above title. It was a plea for prophylaxis in insanity, and he thinks that much would be accomplished in this direction in the twentieth century. He stated that insanity was on the increase in Canada, and thinks it can be duly ascribed to the fact that there have been no preventive measures employed. In order to accomplish good in this direction we must seek either to lessen the demands on, or to strengthen the resisting power of, the brain. He condemns intermarriages in families and also among those of a deranged mentality, and as 50 per cent. of the cases of insanity were hereditary, the descendants of these should be careful in contracting marriage ties. He referred to a portion of one county in Ontario alone where indiscriminate marriage and intermarriage has become most fruitful, and he has seen several members of one family from that locality inmates of the same institution at the same time. He considers that the day may yet dawn when we will give the same attention to the rearing of children as we now give to the breeding of horses. Speaking of farm life and the tendency it has to melancholy, he thought this class of the community should receive education in participating more in the enjoyments of life, and not continue to rot in domesticity. An upheaval in the sentiment and surroundings of the rural homes would work wonders in prophylactic principles.

The following officers were elected: President, H. H. Chown, Winnipeg; treasurer, H. B. Small, Ottawa; general secretary, F. N. G. Starr, Toronto. Place of meeting in 1901, Winnipeg.

Book Notices.

ANNUAL AND ANALYTICAL CYCLOPEDIA OF PRACTICAL MEDICINE. By Charles E. de M. Sajous, M. D., and One Hundred Associate Editors, assisted by Corresponding Editors, Collaborators and Correspondents, illustrated with Chromo-Lithographs, Engravings and Maps. Vol. V. Philadelphia, New York, Chicago: The F. A. Davis Company, Publishers. 1900.

Vol. V. of Sajous' Annual covers all subjects between "Methyl-Blue" and "Rabies." When it is said that this one is up to the high standard of excellence of the former volumes little further need be said. It is the most important and most valuable in the series, including as it does the specialties Laryngology, Ophthalmology, Otology, Neurology, Obstetrics, Pediatrics, and Orthopedic Surgery. It would be invidious to select any of the articles for special criticism or praise, for all are good. Excellent judgment has been exhibited on the part of the editor in assigning space for the various subjects, the amount allotted for the important ones being liberal, and the less important ones do not take more than their value calls for. The contributors are all specialists in the subjects on which they write and consequently all the articles are scientific and reliable, and bring their subject-matter up to date.

A MANUAL OF CHEMISTRY. INORGANIC AND ORGANIC. With an Introduction to the Study of Chemistry. By Arthur P. Luff, M.D., B.Sc.; F.R.C.P.; F.I.C., Physician to the Out-Patients in St. Mary's Hospital; and Frederick James M. Page, B.Sc., F.I.C., Assistant to the Royal School of Mines. Illustrated with 40 Engravings. Cloth, pp. 541. Price, $1.50. London, Paris, New York and Melbourne: Cassel & Co. 1900.

This is one of the standard manuals in Great Britain, and is the work recommended by the *Lancet* as the best text-book on the subject for the student. This revised edition is thoroughly up-to-date, the subject-matter is presented in a very convenient form and does not terrify the student by its compass. While we do not say that it excels some American works, it certainly has merits and advantages, and probably is one of the very best works of its size.

A MANUAL OF CLINICAL DIAGNOSIS BY MEANS OF MICROSCOPIC AND CHEMICAL METHODS, for Students, Hospital Physicians, and Practitioners. By Charles E. Simon. M. D., late Assistant Resident Physician, Johns Hopkins Hospital, Baltimore. Third Edition, Thoroughly Revised. Illustrated with 136 Engravings and 18 Plates in Colors. Cloth. Pp. 558. Price, $3.50 net. Philadelphia and New York: Lea Brothers & Co. 1900.

Amongst the various works on the clinical diagnosis the present holds a creditable place. The author in this edition has revised the subjects throughout and added much new matter. It is a work well suited to the needs of general practitioners, and it has certainly met with favor among them. About one-half of the book is given to urinary examination; it therefore forms a very respectable treatise on the subject by itself. The illustrations are good and we see few things in the author's statements to which we could even suggest a criticism or take exception. He accepts in full apparently the bacilli of Sanarelli as a cause of yellow fever, a point on which many competent authorities are not fully prepared to agree. One or two other minor matters of this kind may possibly be found on reading the book, but it is in many ways fully deserving the favor it has received.

A MANUAL OF PERSONAL HYGIENE. Edited by Walter L. Pyle, A.M., M.D., Assistant Surgeon to Wills Eye Hospital, Philadelphia. Contributors, J. W. Courtney, M.D.; George Howard Fox, M.D.; E. Fletcher Ingals, M.D.; Walter L. Pyle, M.D.; B. Alexander Randall, M. D.; G. N. Stewart, M.D.; and Charles G. Stockton, M.D. Illustrated. Cloth. Pp. 343. Price, $1.50. Philadelphia: W. B. Saunders & Co. 1900.

There are plenty of health manuals in popular literature and books devoted to telling the layman what he must do to care for himself hygienically; many of these are simply embellishments of fads which their authors aim to introduce, others have more or less merit; but there are not very many that the physician can unequivocally recommend. The present volume is evidently intended to make up for deficiency in the literature of this kind, and Dr. Pyle and his collaborators have certainly produced a work that gives the facts in such a form as to be readily appreciated even by the non-medical reader and states these without any admixture of fiction and misdirection. In looking over the work we find very little in it to criticize and very much to commend. It does not exaggerate, and can be referred to as fairly conservative in its statements and, as far as we have been able to see, well up with the data of modern scientific medicine. The illustrations are fairly numerous and certainly a help to the text. The work is one that the physician can recommend to his patients, as it does not overstep the limits in giving information that the layman ought to know.

Deaths and Obituaries.

J. LANGDON SULLIVAN, M.D., of Malden, Mass, died suddenly of heart disease at his summer home in Ashfield, September 5, aged 73 years. He was a native of New Hampshire, a graduate of Harvard Medical School in 1849, a member of the Massachusetts Medical Society and THE AMERICAN MEDICAL ASSOCIATION and had practiced continuously in Malden for fifty-one years.

BENJAMIN HARRISON, M.D., died September 11, near Millwood, Clarke County, Virginia, aged 41 years, of typhoid fever. He was graduated from the University of Virginia, medical department, at Charlottesville, in 1883. After practicing in Clarke County he went to Richmond, where he enjoyed a large practice and was physician to the state penitentiary.

FREDERICK A. MEYER, M.D., died from apoplexy, August 31, at his home in Portland, Ore., aged 61 years. He was born in Breman, and received his degree from the University of Heidelberg in 1860. He had lived for many years in Portland, was for a time city physician, and for eighteen years has been the editor of the *Staats Zeitung*.

ANTHONY B. HANNUM, M.D., died September 1, at Hines, Ala., aged 89 years. He was a native of Kentucky, graduated in 1860 at the University of Nashville, medical department, went to Western Texas and then moved to Alabama, where he practiced for many years.

Dr. Hunter McGuire, of Richmond, Va., died September 19. A more extended notice will be given in our next issue.

Samuel F. Gilbert, M.D., died from dysentery at his home in Elysburg, Pa., August 30, aged 55 years. He was graduated from the department of medicine of the University of Pennsylvania in 1872, and had practiced in Elysburg for nearly twenty-five years.

Dennis Dowling Mulcahy, M.D., died in Newark, N. J., September 11, aged 53 years. He was a Fenian agitator imprisoned in England in the latter part of the 60s and in 1872 he was graduated from the College of Physicians and Surgeons, New York. He had been in failing health for some time.

A. Clarke Emmett, M.D., of Bluff City, Tenn., died at that place, August 30, as the result of a recent stroke of paralysis, aged 57 years. He was a graduate of the College of Physicians and Surgeons, Baltimore, in 1875.

James F. McElroy, M.D., died suddenly September 2, at Bowling Green, Ky. He was graduated from Jefferson Medical College, Philadelphia, in 1866, and had practiced for many years in Warren County.

Walter H. Zink, M.D., died at Branford, Conn., August 27, after a long illness from cancer of the stomach, at the age of 59 years. He was a graduate from the University of Würzburg, in 1862.

John B. Sawyer, M.D., was one of the victims of the storm at Galveston, Tex., last week. He was a graduate of the University of Nashville, medical department, in the class of 1873.

Percy L. Hoover, M.D., died at his home in Mahaffey, Pa., August 25, from Bright's disease, aged 29 years. He was a graduate of Jefferson Medical College, Philadelphia, in 1895.

John L. Barrett, M.D., died suddenly at his residence in Binghamton, N. Y., August 27, at the age of 55 years. He was a graduate of Toledo Medical College, in the class of 1887.

Hubbard K. Burrows, M.D., a graduate of the Kentucky School of Medicine, Louisville, in 1888, died at his home, Box Elder, Tex., September 6.

John F. Ryan, M.D., died suddenly at his home in Roxbury, Mass., September 2. He was a graduate of Tufts College Medical School in 1896.

DEATHS ABROAD.

Pierce Adolphus Simpson, M.A., M.D., died at Auchengrange, Lochwinnoch, Scotland, aged 63 years. He was for many years lecturer on medical jurisprudence at Anderson's College, Glasgow, and later professor of forensic medicine in the University of Glasgow. He was also editor of the *Glasgow Medical Journal.*

Gustav Fraenkel, M.D., died at Breslau, Germany, July 29, aged 68 years.

Miscellany.

Inoculation Against Typhoid.—The government of India, considering the good results obtained from the protective inoculation against typhoid in the British Army, has issued orders to resume measures toward the inoculation of the soldiers entering the army of that country.

The Hospital-Ship "Maine."—This hospital-ship, equipped and maintained by Americans and in charge of American physicians and nurses has made two trips to South Africa. At Cape Town and Durban it received both British and Boer wounded to the number of 354.

Increase in Cancers.—C. Maeder calls attention to the constant increase in cancer shown by the statistics in Prussia, Saxony and Baden. The increase is out of proportion to the natural, apparent increase that would follow the lower death-rate from other diseases. Evidently, he adds in his article in the *Zeitschr. f. Hyg.*, xxxiii, 2, the causal agent is becoming more widely diffused or people are becoming less resistant.

Inoculation Against Enteric Fever.—The late Sir William Stokes, in a letter dated August 2, to the *British Medical Journal* from South Africa, stated that in bad cases of hemorrhage, transfusion of a saline solution at 100 F. either into subcutaneous tissue over the abdomen or into the cephalic veins was employed with good results. Careful records were being kept of cases inoculated and not inoculated against enteric fever. He said that it was yet impossible to give a decided opinion on the adequacy of its protection. Where inoculated cases contracted the disease, the type was as a rule milder. "Unfortunately those who had been inoculated had unbounded confidence in its efficacy, and consequently did not take as many precautions against contracting the disease as they should."

Societies.

Coming Meetings.

American Electro-Therapeutic Association, New York City, Sept. 25-27.

American Public Health Association, Indianapolis, Ind., Oct. 22-26.

Golden Belt Medical Society, Enterprise, Kan., Oct. 4.

Idaho State Medical Society, Boise, Oct. 4-5.

Utah State Medical Society, Salt Lake City, Oct. 4-5.

Wyoming State Medical Society, Cheyenne, Oct. 9-10.

Mississippi Valley Medical Association, Asheville, N. C., Oct. 9-11.

Iowa State Association of Railway Surgeons, Des Moines, Oct. 11-12.

Vermont State Medical Society, Rutland, Oct. 11-12.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, Tenn., Oct. 11-13.

New York State Medical Association, New York City, Oct. 16-18.

Medical Society of Virginia, Charlottesville, Oct. 23.

The Jackson County (Ohio) Medical Society held its first fall meeting, September 11, at Jackson, President Dr. Benjamin F. Kitchen, of Wellston, in the chair.

The Jasper County (Mo.) Medical Society met at Carthage, September 4, for its regular monthly session. Dr. Robert S. Kelso, of Joplin presented a paper.

The Glens Falls (N. Y.) Medical and Surgical Society held its regular monthly meeting September 6, at which an interesting surgical case was reported by Dr. William J. Hunt.

The Hawkeye Medical Society met at Perry, Iowa, and listened to papers by Drs. Oscar W. Lowery, of Grand Junction; John B. Conly, of Woodward, and Frances L. Rogers, of Perry.

The Butler County (Ohio) Medical Society met at Hamilton, September 5. Dr. Frank J. George read a paper on "Scarlet Fever," and Dr. Mark Millikin, of Hamilton, made a practical demonstration of "Intestinal Anastomoses."

The St. Joseph (Mo.) Medical Society held its third annual session, September 11. A paper was read by Dr. Charles H. Wallace, on "Hernia," and Dr. John M. Bell opened the discussion on "Arteriosclerosis."

The College of Physicians and Surgeons, Indianapolis, opened its term on September 20. The changes in the faculty are as follows: Dr. A. J. Banker, of Columbus, professor of obstetrics; Dr. Conrad W. Marxer, lecturer on obstetrics; Dr. John T. Scott, professor of histology; Dr. John F. Benham, professor of chemistry and toxicology; Dr. Harvey Moore, clinical lecturer on genito-urinary diseases, and Prof. R. H. Richards, lecturer on histology.

The Physicians' Protective Association assembled at the Hotel Cadillac, Detroit, Mich., Sept. 4, for its annual meeting and elected the following officers: Dr. Guy L. Keifer, president; Dr. David L. Walmsley, vice-president; and Dr. Augustus W. Ives, secretary.

The Detroit (Mich.) Medical Society and Library Association resumed its weekly meetings, September 10. Dr. Fred. Grover, of Fraser, read the paper of the evening on "The Antiseptic and Antipyretic Treatment of Typhoid Fever."

The Fresno County (Cal.) Medical Society held a meeting September 4. Dr. Thomas M. Hayden read a paper on "Tuberculosis," and a committee was appointed to arrange for the meeting of the Valley Medical Society in Visalia, October 12.

The Chattanooga (Tenn.) Medical Society held a meeting, August 31, at which the physicians and trustees of Erlanger Hospital were present by invitation, to discuss ways and means for carrying on the work of the hospital.

The Denton County (Tex.) Medical Society met in the county court-room, Denton, September 4. The untoward results of quinin were discussed. It was decided that hereafter the society meetings should be held every two months.

The La Crosse County (Wis.) Medical Society held a meeting in La Crosse, September 5. Dr. John A. L. Bradfield presented the paper of the evening on "Diseases and Injuries of the Cornea and Iris," and the discussion was opened by Dr. Mulford.

The Hartford (Conn.) Medical Society held an informal meeting September 3, at which Dr. Joseph E. Root presented a report of his trip abroad, with especial reference to the courtesies extended to him at the meeting of the British Medical Association.

The Kankakee Valley District Medical Society, at its session at Hammond, Ind., September 11, elected Dr. Thompson, of Winamac, president; Dr. James T. Clark, of Hammond, vice-president; Dr. Nelson W. Cady, of Logansport, secretary, and Dr. William Kelsey, of Monterey, treasurer.

The Augusta (Ga.) Medical Society met on August 28, Dr. W. Clifton Lyle, read a paper on "Typhoid Fever," and Theodore E. Oertel exhibited several pathological specimens. The society began its library by subscribing to a number of medical journals.

The Summit County (Ohio) Medical Society held its regular meeting at Akron, September 4. After a discussion of the paper on "Hysteria" presented at the last meeting, Dr. James G. Grant reported a case of internal-ear disease, and Dr. Herman C. Theiss, an especially interesting case of spinal irritation.

The Madison County (Ala.) Medical Society held its regular meeting on September 3, at Huntsville. The subject of the fever so prevalent in the city and county was generally discussed, after which Dr. Julius T. W. Haney, of Madison Station, read a paper on "The Origin of Medical Ethics and Business Relations," and Dr. William C. Wheeler, of Huntsville, presented an essay on "Smallpox."

The Ringgold County (Iowa) Medical Society met at Mount Ayr, September 13, at which the following papers were read: Dr. William Horne, of Mount Ayr, "Gastric Neuroses"; Dr. Albert C. Armitage, of Ellston, "Typhoid Fever"; Dr. Benjamin B. Waring, of Maloy, "Summer Diseases of Children"; Dr. Samuel Bailey, of Mount Ayr, "Hydrotherapeusis"; Dr. M. F. Hannelly, of Tingley, "Puerperal Infection"; Dr. Cassius T. Lesan, of Mount Ayr, "Bacteriology from a County Physician's Standpoint," and William W. Syp, of Knowlton, "Appendicitis."

The Kalamazoo (Mich.) Academy of Medicine met on September 4. Dr. Edward P. Wilbur presented a case of albinism in a young man; Dr. J. M. Elliott read a paper on "Eclampsia in Children," and Dr. Henry B. Baker, of Detroit, secretary of the State Board of Health, read a paper on the "Restriction of Tuberculosis." In the discussion, some members took exception to the regulation of the State Board of Health requiring reports of all tubercular cases, but the consensus of opinion was that the regulation was wise, and that the efforts of the board and its secretary were most praiseworthy.

The Douglas County (Wis.) Medical Society held its annual meeting and banquet at West Superior, September 5. Dr. Joseph A. Rene, president, delivered the annual address. Dr. Charles M. Gould spoke on "The Health Commissionership of Superior." The following officers were elected: Dr. George Saunders, president; Dr. H. Jefferson O'Brien, vice-president; Dr. Patrick G. McGill, treasurer; Dr. John J. Quinn, secretary, and Drs. John Specht, Herbert J. Orchard, all of West Superior, and Dr. Edward T. Gauvreau, of Superior, censors.

The New Hampshire Surgical Club held its annual meeting at the Farragut House, Rye Beach, September 6. President Dr. George D. Towne, of Manchester, delivered the annual address; Dr. George A. Tolman reported an operation for "Strangulated Dermoid Cyst"; Dr. John M. Gile, of Hanover, read a paper on "Surgical Treatment of Gall-Stones," and Dr. John C. Irish, of Lowell, Mass., a paper on "Diagnosis and Treatment of Diseases of the Gall-Bladder and Bile-Ducts." The election of officers resulted as follows: Dr. Ira J. Prouty, of Keene, president; Dr. John M. Gile, of Hanover, vice-president, Dr. Nelson W. McMurphy, of Concord, secretary and treasurer, and Drs. George D. Towne, of Manchester, Nelson W. McMurphy, of Concord, Frank Blaisdell, of Goffstown, Henry L. Stickney, of Newport, and Arthur C. Heffenger, of Portsmouth, executive committee.

The County Practitioners' Club, composed of physicians of Floyd, Clark, Harrison and Washington counties, Indiana, held its quarterly meeting in Borden, September 7. Drs. Benjamin F. and J. Bodine Stalker were the hosts of the occasion. Clinical cases were presented by by Dr. J. Bodine Stalker and Dr. Charles H. Boston, of Bradford; and Dr. Robert S. Rutherford, of Galena made a case report. At the afternoon session Dr. F. Warren Samuel, of Louisville, Ky., read a paper on "Gall-stones in the Common Duct, Their Diagnosis and Treatment." The following officers were then elected: Dr. Benjamin F. Stalker, of Borden, president; Dr. William J. Purkhiser, of Salem, vice-president; Dr. J. Bodine Stalker, of Borden, treasurer, and Dr. Edwin L. Sigmond, of New Albany, secretary.

Spanish-American War Nurses' Association.—During the past week about sixty nurses who served in the Spanish-American war met at New York Hospital and effected the organization of the Association. Only those nurses who were in actual service for at least one month are eligible to membership, but with this restriction it is said that the membership may reach 500. Dr. Anita Newcomb McGee, Washington, D. C., acting asst.-surgeon, U. S. A., is the president, and Mrs. George Lounsbury, Charleston, S. C., corresponding secretary and treasurer. The association will meet next year in Washington, D. C.

Therapeutics.

Ulcers Exposed to Friction.

℞.	Orthoformi—sat. sol. in collodion.......	℥i	32

M. Sig. Apply locally after anesthetizing the ulcer with a 4 per cent. solution of cocain, or with pure orthoform powder.

—Sajous.

Contusion of Eyelids.

℞.	Acidi borici	ʒii	8
	Spt. vini	℥ii	64
	Aquæ, q. s. ad.........................	Oi	512

M. Sig. Locally applied to the wound.

℞.	Tinct. arnicæ.........................	℥ii	64
	Aquæ, q. s. ad........................	Oi	512

M. Sig. Apply cold and change frequently, followed by hot-water compresses when swelling has subsided.

—*Sajous' Annual.*

Cystitis.

E. C. Dudley recommends the following prescription:

℞.	Ext. hyoscyami	gr. i		06
	Camphoræ monobrom	gr. ii		12
	Morphinæ sulphatis	gr. ss		03
	Cocoa butter, q. s.			

M. Ft. suppository No. i. Sig. To be used as a suppository.

FOR IRRIGATING.

℞.	Acidi borici	ʒi	4	
	Sodii boratis	gr. xxx	2	
	Sodii choridi	gr. xv	1	
	Aquæ destil	Oi	512	

M. Sig. Irrigate the bladder with a double current catheter.

—Lobingier: *Sajous' Monthly.*

Freckles—Lentigo.

℞.	Hydrargyri chloridi corros	gr. vi		36
	Acidi acetici diluti	ʒii	8	
	Sodii boratis	gr. xl	2	66
	Aquæ rosæ	℥iv	128	

M. Sig. Apply night and morning, at first gently; later, vigorously.

℞.	Hydrargyri chloridi	gr. iii to viii		20 to .5
	Zinci sulphatis			
	Plumbi acetatis, āā	ʒss	2	
	Aquæ destil	℥iv	128	

M. Sig. Apply two or three times daily. Discontinue for two days when irritation is produced.

—Bulkley: *Cycloped. of Med.*

Chordee.

℞.	Camphoræ	gr. xx	1	33
	Pulv. opii	gr. v		33

M. Ft. pilulæ No. x. Sig. One or two at bedtime.

Chronic Cervical Metritis.

℞.	Potassii iodidi			
	Potassii bromidi, āā	gr. xx	1	33
	Tinct. iodi	ʒss	2	
	Aquæ	ʒii	8	

M. Sig. Inject into the hyperplastic tissue by means of a long syringe. —Monell.

Migraine.

℞.	Sulphonal	gr. xx		
	Phenacetini	gr. viiss		

M. Ft. wafer No. i. Sig. One wafer as needed.

M. Lilgois, in *N. Y. Med. Jour.*, recommends the above as being very efficient in the treatment of migraine.

Impetigo of Face and Scalp in Nursing Infants.

℞.	Acidi salicylici	gr. xv	1	
	Bismuthi subnitratis	ʒv	20	
	Pulv. amyli	ʒii	8	
	Unguenti rosæ	℥iss	48	

M. Sig. Externally applied. —*Med. News.*

Balanitis.

℞.	Potassii chloratis	ʒi	4	
	Aquæ destil	ʒiiiss	14	

M. Sig. Bathe the gland well in this solution and apply the following dusting powder:

℞.	Acidi tannici			
	Amyli, āā	ʒii	8	

M. Sig. Apply locally. —F. Toledo.

Pemphigus in Infants.

℞.	Zinci oxidi			
	Acidi salicylici, āā	gr. xii		8
	Lanolini	℥i	32	

M. Sig. Apply locally. —*Riforma Medica.*

Lumbago.

℞.	Sodii salicylatis	gr. x		66
	Potassii iodidi	gr. v		33
	Ext. sarsaparillæ fluidi	ʒii	8	
	Aquæ destil., q. s. ad	℥ss	16	

M. Sig. At one dose; to be taken in water after meals three times a day. —Nestor Tirard.

Acute Rheumatism.

℞.	Sodii salicylatis	gr. xx	1	33
	Spts. ammoniæ arom	m. xx	1	33
	Aquæ camphoræ	℥i	32	

M. Sig. At one dose. To be taken every two hours until six doses have been taken, or until temperature has fallen and pain has ceased, subsequently to be taken every six or eight hours.

Sansom recommends the above prescription. He finds that sodium salicylate is not incompatible with free ammonia or aromatic spirits of ammonia, and that the above shows no decomposition. —Stevens: *Phila. Med. Jour.*

Hypertrophied Tonsils.

℞.	Resorcini	gr. lxxx	5	33
	Betanaphthol	gr. v.		33
	Aquæ destil.	Oi	512	

M. Sig. Irrigate the tonsils and pharynx twice daily.

Castex, in the *Med. News*, very strongly advocates the use of the above combination.

Coryza.

℞.	Pulv. naphthalini			
	Pulv. acidi borici, āā	ʒvi	24	
	Pulv. camphoræ			
	Ext. violets, āā	gr. xv	1	
	Essentiæ rosæ	gtt x		66

M. Sig. Use as a snuff three or four times a day.

—Exchange.

Superfluous Hairs—Hypertrichosis.

Superfluous hairs can be temporarily removed by the following:

℞.	Barii sulphidi	ʒii	8	
	Pulv. zinci oxidi			
	Pulv. amyli, āā	ʒiii	12	

M. Sig. Make into a paste with water and spread over the part. —Gould.

Impotence.

℞.	Ext. damianæ flu	℥iiss	80	
	Tinct. nucis vomicæ	ʒvi	24	
	Tinct. cinchonæ comp., q. s. ad	℥iv	128	

M. Sig. One teaspoonful three times a day in water.

℞.	Zinci phosphidi	gr. iii		2
	Ext. nucis vomicæ	gr. xii		8
	Ext. damianæ	ʒi	4	

M. Ft. pilulæ No. xxx. Sig. One pill four times a day.

Purulent Ophthalmia of Newborn.

℞.	*Protargol—2 to 5 per cent.*	℥i	32	

Sig. Apply locally three or four times a day, and permit it to remain five or ten minutes.

To prepare protargol the powder is mixed well with water into a paste and then diluted the required amount by the addition of luke-warm water.

Prostatic Pain Following Gonorrhea.

℞.	Tinct. aconiti	ʒi	4	
	Tinct. gelsemii			
	Antipyrini, āā	ʒii	8	
	Ext. ergotæ fluidi	℥i	32	
	Aquæ, q. s. ad	℥vi	192	

M. Sig. A dessertspoonful every two or three hours in a wineglassful of water.

E. R. Corson recommends a combination similar to the above in treatment of prostatitis.

As a Gargle.

℞.	Tinct. myrrhæ	℥ss	16	
	Potassii chloratis	ʒi	4	
	Aquæ destil	℥iv	128	

M. Sig. Use as a gargle four or five times a day.

Alopecia Syphilitica.

℞.	Hydrarg. chloridi corros	gr iii		18
	Chloralis hydratis	ʒi	4	
	Resorcin	gr. iii		18
	Ol. ricini	m. xv	1	
	Spts. vini—90 per cent.—ad	℥vi	192	

M. Sig. Keep the hair short and rub into the scalp daily.

—*Riforma Medica*—in *Clev. Med. Gazette.*

Heart Failure in Typhoid Fever.

℞.	Spts. ammoniæ arom.	ʒiv	16|
	Tinct. digitalis	ʒii	8|
	Elixiris simplicis	ʒiv	16|
	Aquæ destil., q. s. ad	℥iii	96|

M. Sig. Shake. One teaspoonful every three hours.

Crusts of Varicella—Chicken-Pox.

℞.	Acidi carbolici	m. xv	1|
	Acidi borici	ʒiss	6|
	Glycerini	ʒiii	12|
	Aquæ rosæ	℥i	32|
	Aquæ destil., q. s. ad	℥iv	128|

M. Sig. Apply locally.

℞.	Acidi carbolici	m. v	|33
	Icthyolici	ʒiss	6|
	Vaselini	℥i	32|

M. Sig. Apply with a soft cloth.

Ingrowing Nail.

℞.	Liq. potassæ	ʒi	4|
	Cocainæ solutionis—4 per cent.	ʒiii	12|

M. Pack the side of the nail with cotton soaked in the above.

Apply plaster strips to draw the soft tissue away from the nail margin. Never cut the side of the nail. —*Med. Times.*

Dr. Kinsman, in *Columbus Med. Journal,* outlines the following:

1. Remove all pressure from the nail by cutting away a piece of the shoe.
2. Disinfect with hydrogen dioxid until no more "foam" appears.
3. Apply a strong solution of cocain in the base of the ulcer.
4. Apply a drop of Monsell's solution in the ulcer, then cover loosely with gauze. Repeat this process every second day until the edge of the nail is released by retraction of the hypertrophied tissue. The patient suffers no pain from the application, and all pain has disappeared the second day. The cure is effected in a week or two without inconvenience or interference with business. —*Texas Med. News.*

Exophthalmic Goiter in Childhood.

℞.	Strontii bromidi	ʒiss	6|
	Strontii iodidi	ʒiii	12|
	Aquæ destil.	ʒx	40|
	Aquæ menthæ pip.	ʒv	20|
	Syr. menthae pip.	ʒv	20|

M. Sig. One teaspoonful three times a day. —*Med. Record.*

Hepatic Colic.

℞.	Etheris sulph.	ʒi	4|
	Syrupi acaciæ	℥iv	128|

M. Sig. One tablespoonful every fifteen or twenty minutes until the pain is relieved.

Or,

℞.	Chloroformi		
	Tinct. myrrhæ āā	m. xv	1|
	Etheris sulph.	ʒi	4|
	Mucilag, acaciæ	ʒii	8|
	Syr. simplicis	℥iiiss	112|

M. Sig. One tablespoonful every fifteen minutes.

If vomiting is persistent, give small pieces of ice and sedative drinks, and apply turpentin stupes to the abdomen. Liniments are without effect. —*Lemoine: Internat. Med. An.*

As suppositories in the above:

℞.	Ext. belladonnæ		
	Ext. opii, āā	gr. 1/3	|02
	Olei theobromæ	ʒiss	6|

M. Ft. suppos. No. 1.

Formaldehyde in Catarrh.

℞.	Formaldehyde	ʒi	4|
	Glycerini	ʒiv	16|
	Aquæ destil	℥v	160|

M. Use as a spray four or five times a day. —*Merck's Archives.*

Medicolegal.

Dying Declarations Impeachable.—To render a dying declaration admissible in evidence, the Supreme Court of Indiana recognizes, in the case of Green vs. State, that it must be shown that the declarant was under the sense of certain and speedy death. But proof of that, the court says, may be afforded by circumstances, even in the absence of any express statement to that effect by the declarant. Moreover, the evidence on this point, it states, is first for the trial court to hear in determining the admissibility of the declaration. And, after the trial court has decided that the declaration is admissible, the court says, the jurors are entitled to know all of the circumstances surrounding the declarant, in order to determine what credit should be given to the declaration. Then, the court holds that a person accused of crime in a dying declaration is entitled to have contradictory statements made by the declarant introduced in evidence, as an impeachment of the dying declaration introduced by the state, although such statements are neither part of the res gestæ, or essential circumstances of the case, nor dying declarations. It says that, inasmuch as a defendant has no opportunity at the trial to have a cross-examination as to the subject-matter of the dying declaration, it would be most unjust to deprive him of the right of impeachment by contradictory statements, and the right would be lost to him if he were required to lay the usual foundation for that kind of impeachment.

Prohibiting Street Association With Prostitutes.—In Hechinger vs. the City of Maysville, the Court of Appeals of Kentucky holds unconstitutional a city ordinance making it unlawful for any person or persons other than the husband, father, brother or male relative, to associate, escort, converse or loiter with any female known as a common prostitute, either by day or by night, on any of the streets or alleys of the city. The penalty imposed for a violation of the ordinance was a fine of not less than $5 nor more than $20. Manifestly, says the court, the ordinance was intended to accomplish a proper and laudable object. But it does not think that it was properly guarded. It says that there can be no good reason in exempting any male relative from the operation of the ordiance except a husband, father or brother. On the other hand, a mother or sister should be allowed the same privilege as allowed to the father or brother. Moreover, any person should be allowed to converse with such a female long enough to transact any necessary and legitimate business, and no one should be punished for a violation of an ordinance such as the one under consideration unless the party so offending had knowledge or information of the disreputable character of such female. But an ordinance conforming to the views thus indicated, it says, would be clearly within the police power of the city council, and would be a proper and commendable exercise of the police power.

Suggests Case of Fetichism.—The Court of Criminal Appeals of Texas has reversed a conviction of an attempt to commit rape, in Draper vs. State. The prosecutrix, who was the main witness for the state, testified substantially, among other things, that she was 13 years of age; that her aunt had given her to the accused, Draper, when she was about 4 years old, and that she had lived with him ever since; that he was an unmarried man; that for four years he had had sexual relations with her, and that she knew he penetrated her because it hurt her. On the other hand, three physicians examined her, and found her hymen intact, and no evidence of her being penetrated by the male organ, or otherwise. The only variation in their evidence was that one of them thought the parts looked a little flabbier than naturally, which might have resulted from other causes than copulation, and another of them thought there was more elasticity about the hymen and adjacent parts than usual, though he did not know that he would have noticed it if he had not been examining the prosecutrix with reference to this case. Now, the testimony of the physicians, the court thinks, showed her testimony false as to the penetration at least. True, it says, rape could be committed without rupture of the hymen by merely introducing the male organ between the labia, but this was not the testimony. And it declares it unreasonable to believe that the accused had been endeavoring during four years to penetrate her parts, without success, and without leaving any manifestations of his attempts. Not to discredit the story of the prosecutrix entirely, it adds, by way of suggestion, that he may have been afflicted with that form of sexual disease known as fetichism, where the victim, laboring under venereal excitement, simply desires to gratify his lust by contact of his genital organs with any part of the body of a woman.

Aggravated Sufferings from Miscarriage Provable.—The case before the second appellate division of the Supreme Court of New York, of Witrak vs. the Nassau Electric Railroad Company, was one brought by a married woman to recover damages for personal injuries which she sustained in consequence of being struck and knocked down by an electric car. She was pregnant at the time of the accident, and was delivered of a stillborn child about six weeks afterward, the indications being that the child had died but a short time before delivery. The medical evidence showed that the confinement was about ten days late, and the physician who attended her expressed *the opinion that the injury was at least one factor in* producing the destruction of the fetus. Now, in a husband's suit for damages arising out of a personal injury to his wife, as a result of which she suffered a miscarriage, it has been expressly held, says the court, that nothing can be recovered by the husband on account of the loss of offspring. The inquiry is too remote and speculative. And the reasoning which denies a right of recovery to the husband, the court thinks, is equally applicable to a similar claim on behalf of the wife herself. But where the loss of offspring, as in the case of a miscarriage, is accompanied by bodily injury to the mother, or the infliction of pain upon her, such injury or pain, the court holds, is a proper subject of consideration in the assessment of damages. So in *actions of the character of this case, proof to the effect* that the plaintiff's sufferings have been aggravated by reason of a miscarriage caused by the accident, the court holds, is clearly admissible in evidence. The plaintiff is entitled to recover for the physical injury which she has sustained, and for the pain and suffering which she has endured and will endure, as a result of the defendant's negligence. Consequently, so far as a miscarriage or the delayed delivery of a stillborn child augments the mother's physical injury, pain, or suffering, so far, the court holds, is it proper to be considered on the question of damages; but its effect in depriving the mother of offspring can not be taken into account as an element of damage at all. Furthermore, the evidence in this case showed that the plaintiff was badly bruised upon the left leg, knee, thigh, and hip, so that she had suffered a good deal of pain in the year and a half from the time of the accident to the time of the trial. The extensor muscle had been injured, a portion of it being torn from the kneepan, which a medical expert characterized as a permanent injury, causing a lameness that would be lasting. For it all, or rather for all the actionable damages stated, the court thinks an award of $3500 not excessive.

Liability for Delay of Operation.—In the appealed case of the Galveston, Harrisburg & San Antonio Railway Company vs. Hanway, the Court of Civil Appeals of Texas has reversed a judgment for $9000 against both the railway company and a physician who was sued with it for damages on account of negligence alleged to have been committed in delaying the amputation of an employee's foot for twenty-four hours, which negligence was alleged to have caused his death. The operation, when performed by the physician, was properly and skilfully done. This was not disputed. Consequently, the case against the company and the physician depended, first of all, on the question of whether or not he was negligent in postponing the operation a day, and, in order to find the company and him liable in any event, it was essential, the court says, that the jury should find, from testimony reasonably sufficient to enable them to so find, that, if the operation had been performed on the first morning in question, the patient would not have died. Now, not one of the medical witnesses testified that the patient would have lived, had the amputation taken place a day earlier, nor gave it as his opinion that he would have lived. They were unanimous in protesting their inability to say whether or not he would have lived. A number of them said that the chances were less the longer the delay after the conditions once became favorable for the operation. Continuing, the court states that it might have been that, if there had been testimony in the case, such as was claimed, but the court thinks erroneously, as having been given by one witness, that the percentage of deaths in amputations was less than 1 per cent., a finding of the jury that the patient would have recovered would have been sustained, on account of the extreme probability that such would have been the result; for the death-rate in such instances would then have appeared to be practically nothing. But there was no such evidence, as has been shown. The evidence showed that a substantial percentage of the cases of this kind, performed under favorable conditions, result in death. And, if no physician would go so far as to give it as his opinion that an operation a day earlier would have saved the patient's life, the court declares that it fails to see how a jury could have been able to so find. Wherefore, it holds that the company could not be held liable, in this case, for another reason. It appeared that, while it maintained a hospital department in connection with its road, under the control of its manager, and for this it employed a chief surgeon and others, still it was not conducting this department as a business; it derived no profit, but, instead, sustained a loss, therefrom, and that, in fact, the department was not designed for profit. Under these circumstances, the court declares that the company could not be held liable for the negligence of the physicians it furnished, except on the ground of want of proper care in selecting or retaining them. It thinks it different from a case where a large profit had been derived, which went to the company's credit in the bank, with its other moneys. Here, it thinks that the company's obligation was simply to furnish proper attention and treatment, and that this duty was performed when it appeared that the physician in question was competent.

AMERICAN.

1. **Cancer of the Larynx.**—MacKenzie makes a plea for more thorough work in case of cancer of the larynx. He insists on the importance of thorough investigation and removal of all diseased tissue, also the removal of the lymphatic glands of the neck if they are visibly involved. The partial removal of any diseased infectious condition like cancer only stimulates its extension, the operation must be thorough if it is to be effective. He says the time will surely come, if it has not already, when the surgeon will consider it his duty in cancer of the larynx to remove not only the entire organ, but all the neighboring hypertrophied area.

2. **Catheterization of the Ureters in Women.**—Vineberg states that he has used ureteral catheterization over 100 times in fully fifty patients and has never seen any bad effects result, excepting some pain in the twenty-four hours following the operation. He has also carried out the procedure without any anesthetic in the knee-chest posture and the patient has been able to go home from the office shortly afterward. It requires, of course, strict asepsis, and one should wait until he has the ureteral orifice fully in view, then, with a small pledget of cotton soaked in some antiseptic solution, the inside of the cystoscope can be mopped clean and the mouth of the ureter may be cleansed with a second pledget. Then the sterilized catheter is passed directly into the orifice without coming in contact with the vesical mucosa. He reviews the diagnostic and therapeutic indications of the procedure and reports a case in which the introduction of the catheter seemed to be at once curative. He does not explain how this happens to be so, though he offers one or two theories to which he shows the objections.

3. **First-Aid Packet.**—The object of Shields' article is to call attention of physicians, especially those who have to do with communities where accidents are frequent, to the organization of first-aid societies. They are organized by selecting men who are efficient, willing to give some attention to the subject, temperate in their habits, intelligent and conscientious, who will be faithful in attending the meetings of the society and recognize that they are doing it for charity's sake, do not get disconcerted easily, and have no aversion to the sight of blood. He has organized such a society and finds the men zealous and willing and he recommends that they wear a distinctive badge so that it will be known who can be relied upon for help in time of need. The financial part of the work is easily managed, the total of his expenses having been only $50, voluntarily contributed. He has not had to call on any companies, but has no doubt that they would be willing to contribute.

4. **Infant Feeding.**—Palmer reports experience with feeding of infants with modified unsterilized cow's milk in Chicago. The principal effort has been to obtain good, clean certified milk, which was obtained from the dairy of H. B. Gurler, of DeKalb, Ill., and their modifications were not pushed extensively for this milk, which shows no greater variation than mother's milk under normal conditions. Their midsummer mortality with this milk taken into the unhygienic homes of the poor of Chicago was 3/7 of 1 per cent. He thinks that it may be a better argument than any other he can offer to inquire into the mortality statistics of those institutions that use the pasteurized or sterilized milk reduced in its dietetic value.

5. **Hemorrhages After Nose and Throat Operations.**—The chief point of Bliss' article, with a report of five cases of severe hemorrhage, is the importance in looking into all the conditions of the case when operating on the nose and throat. The question of hemophilia would be enough to necessitate this and the tendency to conceal this infirmity renders careful inquiry all the more necessary.

7.—See abstract in THE JOURNAL, xxxiv, p. 1196.

8.—Ibid., p. 1130.

9. **Heroin.**—Loewenthal has used this in 13 cases, 3 of tuberculosis and 10 of whooping-cough. While sceptical at first as to its value, he has concluded that it is superior to anything we have for the treatment of whooping-cough. "If you have a case of pertussis," he says, "and desire results, use heroin."

10. **Renal Casts.**—Martin and Jones have studied the urine in the Royal Victoria Hospital, Montreal, and found that in a very large number of cases without albuminuria casts have been present. They say that it can not but be believed that their actual cause is devoid of the gravity in prognosis usually associated with their presence, that is, without other significant symptoms. This applies to the hyaline and granular varieties, the epithelial casts being less common and probably of more serious import. From their observations, they conclude that they are generally caused by irritating conditions.

13. **Rheumatic Fever.**—The indications in the treatment of rheumatism are: 1. To prevent fresh chilling of the parts. 2. To keep the affected parts at rest. 3. To modify the condition of the blood and neutralize the irritant action. 4. To prevent, if possible, inflammation of the endocardium and pericardium. The author anoints the joints with olive or some other bland oil, and wraps well with two or three layers of absorbent cotton—retained by a lightly-applied bandage. The patient should always be between woolen blankets in a ventilated room with a temperature of 70 or 80. He relies chiefly on potassium carbonate in 10 to 15 gr. doses every two hours to modify the condition of the blood. He thinks that it has a sedative action on the heart, and cardiac complications rarely occur with its use. He is especially opposed to the use of the salicylates, which he thinks are useless and contraindicated.

14. **Dilatation of the Cervix.**—The various methods of dilating the cervix are noticed by Voorhees, who describes the technique and apparatus of the Champetier balloon, its indications and contraindications. His conclusions are: 1. Dilatation of the cervix is readily accomplished by a hydrostatic bag. 2. The best balloon for it is the modified Champetier de Ribes—it being inexpansible, impermeable, strong and inexpensive. 3. The Barnes bag is unsatisfactory. 4. The operation is easy and not dangerous. 5. The *dilatation is rapid.*

6. The uterine contractions always start after its introduction into the uterus. 7. Labor is hastened, and almost always terminates spontaneously after expulsion of the balloon, or the easy extraction of the child is possible. 8. The balloons control hemorrhage in placenta previa, and diminish fetal mortality. 9. The balloons meet all the indications before mentioned.

15.—See abstract in The Journal, xxxiv, p. 1260.

16. **Dislocation of the Heart.**—Abrams describes certain conditions of the heart and stomach which are not always fully recognized and gives the name of gastrectatic dyspnea to the difficulty of breathing experienced sequential to gastric dilatation. He thinks this condition of dilatation of the stomach has not been sufficiently noticed in the literature as an etiologic factor in pseudo angina pectoris, though he has met with cases that were immediately relieved by the treatment of the stomach or a neurasthenic condition which was primarily a factor in the distention of the stomach by gases. The sign of Ferber—that is, the phenomenon of the circulatory tympanitic stomach-lung region disappearing behind the axillary line if the stomach is normal, but if it is dilated, extending to the vertical column—has been very unsatisfactory. The examination after dilating the stomach with air frequently fails to confirm the existence of this sign. He calls attention to a new sign, viz., a patch of dulness or flatness in the interscapular region on the left side, midway between the spinal column and the interior border of the scapula, varying in size from a silver dollar to the entire space between the scapula and the spine. It disappears to be replaced by the normal lung resonance when the patient leans forward and reappears again with the erect position, and is greatly increased by leaning backward. The cause of the dulness is the compression of the lung by dislocation of the heart upward, and the sign is constantly present. He has convinced himself as to the cause of this by introducing a stomach-tube into the stomach and distending it with air, by which he can invariably reproduce the clinical phenomena. The sign may be confounded with the atelectatic zones sometimes present in this region, but these disappear after repeated forced voluntary inspiration, and are not influenced by the position of the patient. In pericardial effusion the sign of Bamberger is important, which is due to exudate compression of the lung. In the erect position there is a space about the size of a silver dollar at the angle of the scapula, over which increased fremitus and bronchial breathing may be elicited. If the patient bends forward the sign disappears, to reappear when he sits upright.

17. **Intestinal Obstruction After Vaginal Hysterectomy.**—Goldspohn reports several cases from which he deduces the conclusion that it is important to avoid adhesions after vaginal hysterectomy, especially by engaging any portion of the small intestine in the closure of the wound. It is necessarily done in cases where extensive abraded surfaces or septic features are present, but where no peritoneal drain is needed it is a just requirement that the cavity be sealed by coaptation of the edges of the peritoneum. The use of the forceps or clamps, so far as it interferes with such closure, is to be avoided. Secondary operations for the relief of post-operative ileus must be performed early, before infection and perforation of the bowels occur. He gives the symptoms and signs pointing to ileus, abdominal distention without marked tenderness to touch, rhythmical colicky pains, slow pulse that is not wiry, fecal vomiting, vermicular motion of the small intestine seen or felt through the abdominal wall, and increased proportion of indican in the urine.

19. **Dermatitis Venenata.**—This condition, which is most commonly observed as a result of contact with poison ivy or poison dog-wood or poison sumach, may be due to many other causes. The author here enumerates, among others, a case of poison from Japanese lacquer, from buttercups, field daisies, golden rod, wood anemone, nasturtiums, tincture of arnica, kerosene oil, the Seven Sutherland Sisters hair-grower, various liniments, etc., etc. This total of causes has a certain interest, as it affords a number of facts which will help, perhaps, to account for some peculiar eruptions, the cause of which is obscure.

20. **The Exercise Treatment of Ataxia.**—The following points should be strictly borne in mind in using the Frenkel treatment: That it is skill, not strength, that is sought to be developed, and it is necessary to begin with elementary motions, as some of the others that would be prescribed for healthy persons are too complex for the ataxic. However simple the movements, the patient must respond with promptness and accuracy to what is demanded. To inculcate these habits from the outset and reduce the difficulties at each step so that the attention and effort will make success possible and will ensure skill and confidence are, says Putnam, the requisites for good results. Dulness, monotony and fatigue on the one hand and superficiality on the other are to be avoided. He mentions certain methods, such as the use of simple tunes played on glasses or bells, calling numbers with varying rates of speed of the notes the patient must touch that are in this line. He thinks it is not sufficient to let the patient carry out the treatment himself by prescribed rules, and there are some cases which are not adapted to this method, such as those that are mentioned by Collins as being weak, anemic, and in those suffering with pain or frequent crises. Two cases, however, he reports do not quite bear out this statement, as improvement occurred in spite of some of the conditions enumerated by Collins.

22. **Trophic Changes in Consumption.**—These changes enumerated are: Idiomuscular contraction, smallness of the heart, pathologic changes in the pharynx, paresis of the soft palate on the infected side, ear troubles, pityriasis tabescentium, pigmentation of the iris and mamilla, changes in the skin, loss of hair, disturbances of sensibility, fatty degeneration of the liver, gastric disturbances, intellectual impairment, increased sexual desire, and amyloid degeneration. Herbert thinks these due to the action of the bacteria and the nerve terminals being affected. He reports several cases of unilateral trophic symptoms corresponding to those of the lesions of tuberculosis on the same side.

23. **Effect of Electric Light on the Eye.**—Roy calls attention to the various retinal changes due to electric flashes, which he finds are always traumatic, the irritation being produced almost exclusively by ultra-violet rays. According to his own observation, the Welsbach gas light is more satisfactory than any other, but he thinks there should be with it an undershade, preferably white, to mitigate the intensity of the light.

25. **General Anesthesia.**—After noticing the different methods of anesthesia and remarking that the Schleich mixture has lost favor to some extent because of lack of experience, prejudice, and the idea that petroleum ether might be dangerous, while he has found it satisfactory, Maduro calls attention to the relation of the boiling-point to the anesthetic action as pointed out by Schleich and believes that if we could adopt the principle of the relation of the boiling-point to the temperature of the body with the anesthetics we employ we should see far less alarming results. Ethyl bromid possesses the relative boiling-point of 38 C., and he thinks it is the quickest in action and the most rapidly recovered from of all. He will, in the future, publish the results of his experience with this anesthetic. In conclusion he insists on the importance of professional anesthetizers, to avoid mistakes that have occurred in the past.

26. **Physiology of Sleep.**—The theory of sleep here manifested is not a new one, it being that of retraction of the processes of the neurone.

28. **Penetrating Wounds of the Chest.**—Two [illegible] especially noticed: diagnosis and treatment. [illegible] trance and exit of air indicates perforation of [illegible] bleeding means nothing. Probing the [illegible] significance of pneumothorax [illegible] noted. As regards treatment, [illegible] cases that the mortality of penetrat[illegible] to hemorrhage: in a few [illegible]

expectant treatment, which is largely in favor with physicians, is, he thinks, not the best. He believes that the mortality will drop quickly and permanently when men have overcome the present fear of the chest and lungs and will resort to bolder measures. In simple perforation, with or without pneumothorax, and with evidence of but slight injury to the lung, and with moderate and stationary hemothorax, the expectant plan may be followed with the probability of good results. The chief worry is the chance of infection, but increasing hemothorax means great danger. Thus, when an external wound is once sealed or padded you limit retraction of the lung by preventing the exit of the air and give place for a larger effusion of blood. Where free entrance of air does not control the bleeding he would advocate free opening of the chest and packing the entire cavity with gauze and using transfusion with normal salt solution in all bad cases.

31. **Genito-Urinary Technics.**—The special points Eastman mentions are the importance of refraining from immediate withdrawal of the steel sound introduced, as is too commonly done, the advantages of cocainization to relieve the patient in case of marked hypersensitiveness, in irrigating the bladder with the Valentine apparatus or large piston syringe, the importance of bearing in mind that a blunt-ended instrument of larger caliber will sometimes pass where the small end of a small sound fails, protection to the clothes, the use of a weak fresh solution of potassium permanganate from a strong solution of known strength, instead of from crystals, which always produce pain, and the open method of ligation in varicocele instead of the subcutaneous one which is out of date, and the disuse of the clamp in cases of circumcision. The clamp devitalizes the tissues and sometimes prevents early healing by first intention. It is, moreover, useless, since the operation can be made easily and sufficiently without it by using the Pean forceps and cutting off behind the forceps jaws, the compressed tissue in this case being part of that which is thrown away.

35. **Goiter.**—The principal point of Powers' article is the treatment, which is the old method of iodoform injections, using these with true antiseptic precaution. He begins with from 5 to 8 drops of a saturated solution of iodoform in Squibbs' ether injected into the gland, and seldom applied it on both sides at the same sitting. In some cases pain is produced, which lasts, however, only a short time. Sometimes, after withdrawal of the needle, he hears a gurgling sound in the gland, but it seems to cause no inconvenience. As the size of the gland is diminished, it seems to harden, and we have to insert the needle deeper to reach the soft glandular structure. His views are based on an experience with twenty cases, of which sixteen were completely cured and four greatly improved.

37. **Hay-Fever.**—Bate considers hay-fever as a form of arthritism, which he thinks is generally admitted. Among the exciting causes, as well as local irritations, he includes sudden emotion and mental impressions. The treatment should embrace both the attack and diathesis. The treatment of the attack consists in establishing the equilibrium of the circulation, freeing the blood from uric acid, relieving hyperesthesia and removing the exciting cause; for the disturbed circulation such medication as raises the acidity of the blood and renders it incapable of absorbing uric acid. He mentions as also of use internal medication by suprarenal extract for its tonic action on the vasomotor system.

38. **The Drug Habit.**—The theory of the drug habit advanced by Rivers is that there is produced in the cells an accustomization to the drug which, when the supply fails, excites the inclination and that the vasomotor stimulants of sufficient power without serious depressing effects, and elimination of the insomerized drug before the effects of the stimulant disappears are a rational method of cure. He believes that of the drugs hyoscin is the safest and best handled, and he would give it in .01-gr. doses at intervals of one hour until intoxication is produced and then keep up the administration sufficiently to keep the patient in a delirious condition. At the end of twenty-four hours the second step, that of eliminating the drug by pilocarpin, is commenced—⅛-gr. dose every hour until there is full physiologic effect, and then continue its use at intervals of from two to three hours until all the hyoscin symptoms have disappeared. Watch the heart in the meantime and meet any glandular symptoms with atropin or morphin. If, at the end of this time, the patient expresses absolutely no desire for the drug the work is done, if, however, he still feels the need of his accustomed stimulant the treatment should be begun again. There is apt to be a bilious diarrhea following this method, which is usually easily controlled by bismuth or, if necessary, resorcin. He does not include alcoholic cases in this method of treatment, as the indications vary somewhat. He begins in such cases with a mercurial purge, and then proceeds as before, though using less hyoscin and pilocarpin. He has used this treatment in twenty-three cases, of which fifteen were alcoholic. They were all relieved with but one exception. He has had two bad results, both alcoholic, neither of them, he thinks, due to the treatment.

41.—See abstract in The Journal, xxxiv, p. 1487.

42. **Ligation of the Abdominal Aorta.**—Keen reports a case of ligation of the abdominal aorta for aneurysm in which the patient lived forty-eight days, collateral circulation having been established. The death was due, as in other cases, to cutting through the vessel by the ligature. To prevent this accident, which seems almost universal, he has devised an instrument for the compression of the aorta, which he illustrates, and which avoids the danger of pressure on the thoracic duct and requires only the opening of the abdomen and its application to the vessel. This instrument has been experimentally tried on dogs and the following are the conclusions deduced: 1. That in dogs paralysis of the hind legs follows complete obliteration of the aortic stream. 2. That the paralyzed parts may regain their entire health even after forty-eight hours' compression. 3. That three and one-half hours of compression will not interfere with the complete restoration of the paralysis. 4. That at least, after twenty-four hours, and possibly less, the collateral circulation may re-establish the continuity of the circulation. 5. That the aorta may be clamped in the dog for one hundred and ten hours, and yet the collateral circulation be established sufficiently to nourish the posterior extremities. 6. That the clamp can be placed on the aorta, at least in the dog, either in separate parts or as a whole. 7. That it can be readily removed without injury to the aorta.

43. **Granular Degeneration of the Erythrocytes.**—The granular changes in the red corpuscles that carry any certain disease, such as chronic lead poisoning, malaria, anemia, carcinoma and septic disorders, are observed and discussed by Grawitz, who concludes that their presence or absence is sometimes of considerable importance, as it permits us to decide on the etiology in certain anemic conditions and enables us to determine whether true blood-poisoning exists or whether the anemia is to be considered as but one symptom of a general cachexia. Granular degeneration is only a symptom which must be taken with other symptoms of the disease. The recurrence of these granulations is of no significance, but in certain cases of lead poisoning which are hard to recognize, also in those cases where the existing anemia is to be referred to malignant neoplasm, chronic nephritis or similar diseases, they are of value. In many cases granular degeneration appears as the first definite sign of anemia, where it is of special importance. In other cases, like tuberculosis, the anemia is not attended with this symptom and, therefore, we must not here look at it as depending on the destruction of the blood-cells, but on the involvement of the blood in the general tissues, that is there is a true oligemia, a reduction of the general amount of the blood. He thinks that a high temperature is sometimes its cause, and in this respect it is similar to that of many cases of tropical anemia.

45. See last week's Journal, p. 692.

52. **Gonorrheal Pyelonephritis.**—The report of a case, with careful autopsy and bactericidal examination, in which

only the gonococcus was found, has led Lewis to question the reported rarity of the condition from this exclusive cause. He argues against this, showing that it is practically possible to have ascending infection by continuity, as in the case he reports, or through the lymphatics, or by general infection or metastasis. He refers briefly to a case of gonorrheal rheumatism in which cultures of the blood produced abundant colonies of gonococci responding to the tests, and succeeding generations of germs were cultivated from these.

55.—This article has appeared elsewhere. See THE JOURNAL of September 1, title 31, p. 583.

57. **Hearing of Deaf Mutes.**—Bezold reports the results of testing, with an improved apparatus, a number of deaf mutes that had been formerly examined, and he finds the number of totally deaf less than before, though two of the cases had lost considerable hearing in the interval. The details of the test are given and the results indicate that special care assured to the partly hearing and partly vocal deafmutes will increase not only what speech and hearing they may have, but also that this fraction of normal hearing power can be utilized in teaching sound language.

60. **Nasal Empyema.**—The conclusions of Cobb's article are given as follows: 1. That the whole chain of catarrhal symptoms of the nose, the nasopharynx and of ears is due to empyema of the nasal accessory sinuses. 2. That this empyema is the result of an infective inflammation of the accessory sinuses in which the drainage is insufficient. 3. That the malformation of the posterior end of the middle turbinate, which he has described in this paper, plays an important part in the establishing of the nasal empyema which causes postnasal catarrh. 4. That chronic catarrhal inflammation of the middle ear may result from the catarrhal condition of the nasopharynx, either by extension of the disease, by continuity of tissue, by the forcible blowing of the irritating secretion into the middle-ear cavity, or by closure of the Eustachian tube from involvement of the mucous membrane in or around its entrance. 5. That there is no evidence of chronic catarrhal inflammation of the middle ear is caused by obstruction to nasal respiration, unless the obstruction is associated with empyema of the accessory sinuses. 6. That those cases of chronic catarrhal inflammation of the middle ear which are caused or made worse by nasopharyngitis can not be cured until the nasal empyema which causes the nasopharyngitis is first cured, and that mechanical treatment directed to the ears is only palliative and does not free the patient from the danger of an acute exacerbation of the disease. 7. That many cases of nasal empyema may heal spontaneously under favorable conditions, and the more recent the case the more probable it is that this will occur. 8. That the accessory sinuses have a tendency to free themselves of inflammation, and that treatment should be directed to assist nature to this end. 9. That it is possible to cure practically every case of nasal empyema, and therefore every case of nasopharyngitis depending on it.

72. **Normal Salt Solution in Typhoid.**—Andersen reports in detail a case of typhoid with severe hemorrhages, causing collapse, in which relief was obtained by the use of transfusions of normal salt solution. Several other cases were treated similarly with benefit, but none so bad as the one reported. He does not find reports of similar treatment for hemorrhage of the bowels in typhoid. In his case the operation was done in a tent without antiseptic appliances, and some abscesses followed, which he attributes to the fact of the saline solution not being filtered.

74. **Pulmonary Tuberculosis.**—In the treatment of pulmonary tuberculosis, Whalen considers guaiacol first among the drug preparations. He has been in the habit of giving it, 5 minims in capsule after each meal, with benefit. Next to this, he would use oil of cloves similarly administered. His experience with this has also been favorable. Iodin is of some use in certain cases, but inferior to the drugs mentioned, and is of most value when used by inhalation. Tonics such as strychnin, arsenic, phosphorus or cod liver oil are useful and should not be overlooked. Of late he has been using Armour's red bone-marrow in place of the malt and cod-liver oil, and finds it a valuable remedy. Alcohol in the early stages is not advisable, later it may be of benefit, and should be chiefly prescribed in the form of malt liquors. The diet should be as nutritious as possible, and special attention given to the digestion and assimilation. Internal medication can be aided by inhalation of various drugs, among which he places formalin first, though the essential oils of cinnamon, cloves and thymol are of value, as well as iodin, cod-liver oil, etc. Moderate exercise, together with lung gymnastics, is also spoken of with favor, as are cold applications to the chest followed by vigorous friction. The diarrhea which occurs he has been able to control with bismuth, and night sweats with atropin. Hemoptysis, as a rule, requires no treatment, though if necessary morphin is valuable, and he sometimes gives aconite to reduce the blood-pressure, also nitroglycerin. He has faith in the use of serum treatment, or tuberculin, and his experience with the compressing method of Murphy has not led him to have great hopes of its curative effects. Other subjects mentioned are the climate and altitude of various health resorts, and their respective merits are discussed.

75. **Suggestion Without Hypnotism.**—Moyer considers suggestion, well directed, patiently and systematically applied, a very important element in many diseased states. Hypnotism, on the contrary, has many objectionable features, and he thinks there is little use in inducing the hypnotic state. He does not say it is always useless, but it should not be practiced in a routine way, and when employed it should be only by medical men.

81. **Obstruction of the Upper Air-Passages.**—The general subject of obstruction of the nasal passages, etc., is gone over by Gardner, who finds it, regardless of cause, a distinct pathologic entity, producing certain well-defined disturbances of nutrition, alterations of the bones and contour of the face and palate and disturbances to sleep, predisposition to infection and chest deformities, as well as deafness, either from pressure or Eustachian involvement. With the attainment of maturity these conditions may become inoperable and results permanent. He holds there is hardly any class of cases where prompt treatment is as beneficial or procrastination more damaging.

82. **Head-Last Presentation.**—In this communication Hunt refers to a method of rapid birth of the head by placing the patient on the left side and producing pressure from over the fundus toward the buttocks. He claims that this method will result in saving the lives of many children. The pressure is toward the inlet of the pelvis and the possibility of injury is comparatively slight.

86.—Ibid.

87.—Ibid., p. 115.

88.—Ibid., p. 116.

89.—Ibid., p. 115.

90. **Cold in Pneumonia.**—The use of cold for therapeutic purposes in pneumonia forms the subject of Rees' article, in which he reviews the opinions of various authors on the subject. He finds that it is valuable for pain in this disease, as its anodyne action has no effect on checking elimination, disturbing digestion, impairing the appetite or depressing the nervous system. It is also useful for the relief of general restlessness and delirium for the same reasons. The ice-bag slows and strengthens the heart-beat, and the pain being relieved, the patient unconsciously takes deeper breaths. The major argument for its use, however, is the effect on the circulation. It limits the congestion and consequent exudate and prevents the involvement of large areas of tissue. Sustained cold applied to the skin relieves the tendency to exudate and excessive diapedesis of leucocytes: 1, by constricting the cutaneous arterioles, and, 2, by setting up compensatory dilatation in the pulmonary and bronchial arterioles by the means of which the flushing out of the local stasis is favored. It has also a valuable, and by no means a slight, action on the gen-

eral temperature and acts as a safe and natural diuretic. The number of ice-bags used should depend on the size of the inflamed area and the stage of the disease; enough to cover the inflamed lobe should be used. It is not, however, applicable to every case, and should not be employed in young children and in the aged where the system is already depressed or weakened from causes prior to or complicating pneumonia. In very young children or in the old or feeble, where the strength is rapidly diminishing and cardiac and respiratory failure threatened, a cold sheet wrapped closely around the trunk and left there for a few minutes and reapplied at intervals of one or two hours is a powerful stimulant. Cases have been under his observation where this seemed to save life.

93. **Laceration of Urethra.**—The motive of this study, as stated by the author, is to ascertain the accepted management of the catheter after laceration of the male urethra and what is the prevailing opinion as regards suturing the laceration. He reviews the different authorities and their different views and reports a case. From his experience and reading he deduces that there is not sufficient positive information regarding the time the catheter should be retained. In Leipziger's case, if he had retained it for fourteen or twenty-one days at the first, instead of removing it at the seventh and then returning it for thirteen days more, the results would, he thinks, have been better. Leakage through the perineal wound need not cause any anxiety, as fresh urine does not harm the wound if it can be cleansed, and it makes no material difference whether the wound heals around the catheter by suture or granulation.

101. **Diaphragmatic Hernia.**—On the basis of a case successfully treated, and a study of others reported, Walker comes to the following conclusions: 1. In all cases of so-called internal strangulation one should always think of the possibility of a diaphragmatic hernia. 2. When the physical examination reveals the diaphragmatic hernia as probable, an operation is imperative when the symptoms of obstruction are present. 3. In recent cases, if the diagnosis has been made early, laparotomy is probably the better operation. 4. In old cases, on account of the difficulty of reducing the gut, ligating the sac and stitching the rent in the diaphragm, the transpleural route is preferable. 5. If, after making a laparotomy, the gut can not be reduced, a thoracotomy is justifiable.

102. **Hysterectomy.**—The chief point of Haughey's article is the plea for the complete operation of hysterectomy, instead of removing the ovaries in cases of chronic disease of the appendages. He does not see the use of the removal of the appendages and not the uterus. He believes the results of the combined operation are in every way more satisfactory than that of the single one which may require subsequent removal of the uterus afterwards.

117. **Gunshot Wounds.**—Osborn pleads for the operative interference in gunshot wounds of the abdomen. He thinks that the mortality would be greatly reduced if this were done, and reports cases where he has seen the "do nothing" treatment result in rapid death from perforation of the arteries, which might have been readily relieved by abdominal section. The anesthetic will also be the best treatment for shock.

120. **Vaccination.**—Lehmann's improved method of vaccination consists in gently stroking the surface of the skin, after making it tense, with the vaccin point, steadily increasing the pressure until the skin is rendered anesthetic, or is hypnotized, so to speak, by this local pressure and gradually increasing friction. Then, when it is sufficiently scarified, the two sides of the vaccin point are moistened with rainwater and passed over the denuded area, and a bit of tissue paper held over the spot until it is dry. Lehmann claims that this method minimizes irritation and is altogether in various ways better than those commonly used.

125.—This article has appeared elsewhere. See THE JOURNAL of July 14, title 95, p. 118.

132. **The Prophylactic Douche.**—The writer contends, after giving a brief review of the literature upon the subject, that the weight of testimony is in favor of discarding the douche as a routine measure, although some observers still adhere to their former contention as to its benefits. Even the preliminary douche is of doubtful utility, as the vaginal secretions possess bactericidal properties, they are useful and protective, and the various species of micro-organisms will meet with more timely neutralization without the douche than with it. The secretions may contain a great number and variety of bacteria, but usually they are non-pathogenic or produce but a moderate rise in temperature. Severe puerperal fever and death is generally due to infection from without, but it may have a cystogenic origin. Recent investigations go to show that the blood, the lymph and the tissues generally are not always sterile. In the puerperal state there is a greater liability of an accumulation of bacteria within the tissues than at other times, and nature has provided an extra channel of elimination for just this condition, and one of the chief provinces of the physician is to aid nature in this elimination.

141. **Hypnotism.**—Martin defines hypnotism as the effect of suggestion made during sleep. Simple suggestion is an impression made either when awake or during sleep. He divides all classes of cases in which suggestion or hypnotism can be used into those in which nothing does so well and those in which it will be of great assistance to other treatment. Among the first of these he includes persistent insomnia, nausea of pregnancy, pressure pain of pregnancy and wrenched back. Those where it may help are multiple. He insists on the importance of using hypnotism only rarely, and then when the case demands it. He advises the physician to read Moll's work first, then Bernheim, and then he will probably be well enough placed on the subject to read more extravagant authors without believing all they say.

FOREIGN.

British Medical Journal, September

Treatment of Malaria by Quinin.—In this discussion, in which a number of prominent English and Anglo-Indian physicians took part, the question of the prophylactic action of quinin was taken up. Dr. Duncan reviewed the statements of others chiefly, but found as a general conclusion that there is little doubt that quinin does exert a prophylactic action and its curative action is undeniable. It acts probably by destroying the organism, though there are several theories as to how it is done; whether it works on the spores or on the large intracorpuscular forms or stimulates the phagocytes is as yet not absolutely decided.

Dr. Buchanan, superintendent of the central gaol, Bhagalpur, Bengal, had submitted a series of questions to the medical men in India and received replies. Nearly all were in favor of the prophylactic issue of quinin; some of them have been criticised, hence several special papers were published by the medical officers reporting experiments made with special reference to meeting the criticisms. The results are strongly in favor of the prophylactic issue of the drug. If the statement of Capt. Fearnside, in the *Indian Medical Gazette* of September, 1899, can be substantiated that it prevents the formation of crescents, a very important argument in its favor will be established.

Buchanan has been giving for five years daily a dose of quinin or cinchonidin to, on an average, over 16,000 persons for the four months of the rainy season, and has never seen a single bad result.

Dr. Robert Fielding-Ould disagrees entirely with the idea of giving a regular dose of quinin to prevent malaria. He finds that it disturbs the peptic digestion and is apt to lead to congestion and torpidity of the liver. There are exceptions, he admits, where men can take the drug in quantities for years, but these objections, he thinks, are sufficient to condemn its general use. In conclusion he mentions quinin hemiglobinuria, of which he claims a number of cases are on record.

Other partakers in the discussion expressed varying views. Dr. Manson considered the prophylactic action only a phase of its curative effect and recommended the use of the microscope in future experiments with quinin as a prophylactic. Dr. Rees, superintendent of the London School of Tropical Medicine, found that its prophylactic action, while it did not prevent, markedly reduced the number of attacks and lessened their severity and mortality. He would use it himself if he should return to a malarial country. The majority of the authorities seemed to be in favor of its prophylactic value.

On the Metamorphosis of the Filaria Sanguinis Hominis in Mosquitoes. S. P. James.—The writer reports his own observations and experiments on the metamorphosis of filaria. He thinks that the statement of Dr. Manson that he was able to observe complete metamorphosis in seven days was probably due to the fact that there are a number of species of mosquitoes, some of them much more favorable hosts than others, and that Dr. Manson's experiments were made with one of the latter. He reports his own experiments, showing how he has found the filaria in the proboscis and apparently favoring the view that the filaria pass directly from mosquito to man without having first existed for some time in water. He believes that the genus Anopheles are capable of acting as efficient hosts as well as the species of the Culex.

Notes on the Etiology of Filariasis.—Maitland disagrees with the view that the common origin of filariasis in the human subject is due to mosquitoes, and holds rather that it is a water-borne disease. He adduces in favor of this the fact that the white race in the tropics is comparatively immune, while the native population suffer, that certain communities having a common supply of drinking water suffer severely from the disease while others taking their supply from different sources are not affected. The immunity of the Europeans is due to their habit of drinking only boiled or filtered water. As an example of water transmission he reports the case of four Eurasian boys who took to bathing in and drinking the water from a certain pond and became simultaneously affected with filariasis. He asks: If the theory of inoculation is correct how is it that persons affected with filariasis can live in intimate association with others and not infect them?

A Discussion on Ankylostomiasis.—The anemic affection attributed to ankylostomiasis is discussed by Giles, who has investigated the subject in Assam; there, the mortality is very high alike amongst the indigenous inhabitants and the imported laborers that come to work in the tea plantations. The question whether this increased mortality is due to malaria plus ankylostomiasis advanced by some authors, he does not discuss; his aim was to study the life history of the worm. The recent view as to its absolute harmlessness, he thinks, is erroneous. Of course, where a large portion of the population suffer from the disease many healthy individuals will also have the parasite without necessarily becoming its victim. His own impression is that it is responsible for a formidable mortality and a still greater amount of sickness wherever it exists.

Fearnside has investigated the subject among convicts and finds that about 72 per cent. of the persons in the district investigated harbor the parasite and remain in good health. He thinks that the figures show that the effects of ankylostomiasis are for the most part secondary and not primary. They seldom occur in such numbers as to cause true ankylostomiasis and the bad effects are mainly the results of such disorders as malaria, dysentery, etc., complicated by ankylostomiasis.

Rogers recognized the anemia produced by long-continued small loss of blood through the gastrointestinal mucosa caused by the presence of several hundred ankylostoma acting for several months, or by a still larger number acting for a short time. This is ankylostomiasis, and it is characterized by the reduction of hemoglobin to nearly twice the extent of that of the red corpuscles; while in the disease called kala-azar and in malaria the red corpuscles and hemoglobin are reduced in a parallel manner. This makes a difference in the treatment of the two forms of anemia; in the one the hemoglobin is being drained away and can be replaced only with great difficulty, especially in vegetable-eating people, and in the other hemoglobin is not lost to the system but is stored up in organic combination in the liver and spleen, whence it can be reabsorbed to restock the red corpuscles as they are turned out. Hence, in ankylostomiasis iron is urgently indicated, while arsenic is of less importance; but in the other form arsenic and bone-marrow are specially indicated, while iron is not urgently required.

Baker notices the prevalence of the condition in Burmah, which he attributes to the habits of the population and absence of night-soil sanitation, thus producing infection. Ross holds that the idea that a certain large number of parasites are required to produce the mischief in this condition is erroneous; 50 ankylostoma might destroy a patient already debilitated by other disease or starvation, and he mentions the possibility of the parasites having also toxic effects.

Tropical Liver Abscess. Kenneth Macleod.—Sporadic evacuation of abscesses of the liver most commonly occurs along the pulmonary route, the principle of progress in the direction of less resistance coming into play. Whether the abscess bursts into the pleural cavity or erupts into or erodes the lungs or produces a secondary abscess must depend on the extent and strength of protective pleuritis to which the progress of pointing has given rise. When the discharge into the pleura is primary the physical signs are characteristic and exploration can make certain the diagnosis. There is then but one line of treatment, that is, to make a free opening and drain under antisepsis. When it finds its way into the substance of the lung, symptoms of diaphragmatic pleurisy and lung consolidation are superimposed on the liver symptoms and if the latter are well marked exploration through the liver and direct drainage by incision is the proper treatment, but frequently the expectoration of a large quantity of pus is the first sign. In favorable cases it may diminish and the patient may make a complete recovery, but in other cases the pus refills and death with hectic symptoms occurs. The question arises, What should be done in these aggravated cases? He criticises the text-book instruction to always incise and drain through the liver, and urges that in these cases it should be treated as one of lung cavity and exploration and incision made through the chest. He bases his opinion on two grounds:

1. While the lung is undergoing destruction, in the liver repairing changes are taking place. 2. He has frequently seen that method followed without success. His objection is, to sum up the matter in a few words, that in the old-standing cases of lung lesion consequent on hepatic abscess the pathologic burden has been transferred from the abdomen to the chest and the relief measures must be applied accordingly, the lung lesion treated according to special indications of the case, and the liver is left to take care of itself.

Subphrenic Abscess. James Cantlie.—In this article on subphrenic abscess Cantlie describes the symptoms and diagnosis, which may be confused with gall-bladder inflammation, and when the history is not obtainable the surgeon must be prepared to meet either of the conditions. The prognosis is generally good. The treatment consists in simply tapping with a large trocar and drainage by a large tube, but incision when adhesions are known to have formed is free from danger, and in one case in his observations it was eminently satisfactory. He demonstrates in his article the position of the inferior vena cava and states that by a study of frozen sections it is possible to ascertain how deeply the needle of the aspirator or trocar can be carried into the liver without causing untoward consequences from hemorrhage. He finds in a body with a circumference over the hepatic area of 32 inches that the center of the inferior vena cava is from 4¼ to 5 inches off the surface, in a line drawn horizontally from the neighborhood of the xiphosternal articulation to the angles of the ribs behind. Before commencing an exploratory puncture of the liver, therefore, Mr. Cantlie recommends that the circumference of the body be taken, and, starting with the above measurement as a basis, a fairly accurate idea of how deep the puncture may be carried is ascertainable. In a body measuring 32 inches in circumference, it is not safe to penetrate deeper than 3¾ inches in a horizontal direction from anywhere in the line mentioned. For every inch of circumferential measurement above or below the 32 inches, ¼ inch may be added to or subtracted from the depth it is safe to penetrate. Abstraction of blood in inflammatory hepatic derangements Mr. Cantlie regards as most salutary. When the needle enters a large vessel in the liver substance, as judged by the free flow of blood in the bottle, he allows the needle to remain until 6 to 10 ounces of blood are withdrawn. No ill effects follow tapping a vein in this position; it is only when the inferior vena cava, or the trunk of the portal vein before it breaks up in the liver, is wounded that a dangerous hemorrhage is likely to follow. Every puncture of the liver by a needle causes a slight or even considerable flow of blood subsequently into the peritoneal cavity, as he had been able to prove clinically; but in all probability it was this very flow of blood which contributed to the marked benefits usually following liver puncture. The dangers of hepatic hemorrhage are confined to puncturing the inferior vena cava, the extrahepatic portion of the portal vein, or penetrating a mass of malignant tissue occupying the liver.

The Diagnosis and Surgical Treatment of Tropical Liver Abscess. W. Johnson Smith.—The writer holds that exploratory puncture is preferable to laparotomy in case of tropical abscess. He sees no good grounds for opening the abdomen unless the repeated use of the needle and syringe has failed. If the characteristic fluid of a liver abscess be drawn up, an operation for allowing it a free discharge should be immediate. Thoracotomy almost always implies a transpleural incision, and while he has found that in an abscess in front requiring an operation adhesions usually exist, yet in the more frequent form of posterior abscess the lung and liver are usually found quite free, and their respective serous cavities quite open. Consequently in this operation we expose two large serous cavities and that doubles the risk of infection. There is also a risk of permitting ingress of air into the pleural sac, causing lung collapse. Notwithstanding these risks, drainage in suitable and favorable cases has on the whole been satisfactory. The surgeon must guard against the risk of infecting the pleura and peritoneum. He has followed the plan of making a thorough incision in both diaphragm and liver so as to allow a full and uninterrupted discharge of the fluid contained in the abscess. He thinks it would be well to apply our tests for both general and local leucocytosis in every case of liver abscess to see if leucocytosis is present.

Annales de la Soc. Med.-Chir. de Liege, June.

Foreign Bodies in the Lungs. E. Gulikers.—A young man supposed that he had swallowed the metal tip of a pencil, about an inch long, but the total absence of pharyngeal reflexes suggested that it might have passed into the air-passages, and a skiagraph showed it horizontally lodged near the eighth rib. The patient coughed and expectorated in the morning, but was not otherwise disturbed by its presence. He was advised to lie on an inclined plane, head downward, which he did for eight days. At the end of this time he felt the foreign body slip down into his throat and, as instructed, he supported himself on his arms, made slowly a deep inspiration, and then, uttering a bass sound—to open his vocal chords—expelled the foreign body without coughing. In the second case a child had inhaled a toy arrow from a blow-gun—a metal pin 1.75 inches in length, with a tuft at the head. It was expelled six months afterward with a vomica, after an interval of recurring pleurisy, hemoptysis and an almost constant cough.

Bulletin de l' Academie de Medicine (Paris), August 21.

Neuropathic Hematuria. E. Lancereaux.—Hemorrhage may occur in the urinary organs of men and women and in the genital organs of the latter, independent of any material disorder, and due solely to a disturbance in innervation. They are more frequent in neuropathic patients and are generally preceded by fatigue, exposure or violent emotion. The treatment should be addressed to the nervous system, after controlling the hemorrhage. and quinin will be found extremely useful, combined with hydrotherapy. He cites several personal cases in which .8 to 1.5 gm. of quinin sulphate arrested the hematuria in a few days. His patients were mostly rheumatic or hemorrhoidal subjects, and he has noticed that the suppression of hemorrhoidal hemorrhages is a frequent preliminary to hematuria. Zambaco has also noted this latter fact, and mentions that injecting the veins of the rectum in a post-mortem preparation from a hemorrhoidal subject is liable to distend simultaneously the veins in the bladder, which, in one instance, were dilated to actual varices. He concludes by stating that the prognosis of neuropathic hematuria is not grave. Its recurrence may lead to anemia, but symptoms of debility are rare and less pronounced in hematuria from vasomotor disturbances than in hemorrhage of any other origin.

Echo Medical (Lille), August 26.

Traumatic Valvular Lesions of the Heart. Castiaux and Laugier.—Both of these authors are prominent in legal medicine and presented this communication at the International Medical Congress. The main points are as follows: Violent contusions of the thorax, whether from a fall or blow, or compression between two resisting bodies, are capable of producing a valvular lesion even in a healthy heart, and still more easily if the organ be diseased. These valvular lesions are almost always immediate—rupture or laceration—but they may also occur later, and only appear subsequent to a myoendocarditis resulting from the traumatism. When they are immediate they produce insufficiency of the injured orifice from the start, liable to be complicated later with pathologic processes from lesions of the endocardium, of some other orifice or of the large vessels of the heart. The aortic is the valve most frequently injured from this cause—25 out of the 36 cases known to date; next the mitral, with 8, and exceptionally the semilunar with 2 and tricuspid with 1. The physical signs are about the same as those of a spontaneous valvular lesion, but the murmurs are more intense and prolonged and the flaps of the valve or torn chordæ floating in the blood current impart a peculiar tone and vibration to the morbid sounds. The prognosis of traumatic insufficiency is more serious than that of spontaneous lesions and the course of the affection is more rapid. The organ is overwhelmed suddenly. Long survival is, however, possible and even recovery, although extremely rare. When a cardiac affection is the result of external traumatism the responsibility of the author of the injury is singularly aggravated. An unpublished case is described in detail. Besides intense signs of aortic insufficiency, there was a holodiastolic, musical, slightly piping "steam tug" murmur.

Branchial Fistula of the Neck. O. Lambert.—The fistula in question was undoubtedly congenital, but remained latent for fifty-six years, when some infection produced a small abscess in it, with perforation outward, thus disclosing its existence for the first time.

Nord Medical (Lille), August 15.

Connection Between Pure Mitral Stenosis and Heredo-Syphilis. Duvivier.—The etiologic influence of inherited syphilis in the production of pure mitral stenosis was unmistakable in thirty cases which Duvivier has collected in the literature. It was likewise probable in two cases he had occasion to observe in Combemale's service. He agrees with Lancereaux that teratology of the heart is merely the pathology of this organ during intrauterine life, and with Huchard that pure mitral stenosis is always congenital.

Pneumonia in the Aged. Lemoine.—Pneumonia in a fresh and well-preserved elderly person runs the same course as in a young adult, but in senile conditions, or when excesses have ruined the constitution, the course of the pneumonia is quite different. The temperature is less by a degree or more than that of typical pneumonia in the adult. The expectoration is less, the sputa greenish and dirty, and the lesions localized at the apex. Sometimes auscultation is entirely negative; the focus is deep and covered with emphysematous portions of the lung. There are seldom crepitant râles; the large subcrepitant râle is ordinarily the only one to be heard, and this may not make its appearance until the close of the disease. Some cases progress to the fourth or fifth day with no manifestations except dry tongue, red at the edges, and temperature not over 38.5 C. The first indication is to diminish the afflux of blood and relieve the distress in breathing. The only revulsive that can be used on these feeble subjects is extensive dry cupping, daily repeated. Puncture is hazardous and respiratory stimulants are preferable. For this Lemoine administers 2 to 6 gm. of ammonium acetate in syrup during the twenty-four hours. It acts directly on the respiratory centers and increases the diuresis. He sustains the heart and general system with digitalis and alcohol. In case of persons habituated to the use of alcohol, musk will be found a powerful substitute tonic. He prescribes .5 gm. musk mixed with one yolk of egg and 150 gm. water, given by the mouth. Or it can be taken in two cachets, .25 gm. each. Give liquid food if possible, preferably milk. It is important to facilitate expectoration, but the usual measures can not be used in these cases, and the best results are attained by administering a stimulant, such as strychnin.

Presse Medicale (Paris), August 22 and 29.

False Cures of Pleurisy. E. Sergent.—A young woman with metapneumonic interlobar pleurisy was apparently cured in consequence of the spontaneous discharge from a vomica auscultated in the middle, posterior axillary region. Pure cultures of pneumococci were obtained from the pus. Two weeks later her right arm was temporarily paralyzed. Although otherwise healthy, the persistence of a vesicular murmur at the point of the vomica suggested that it had not completely healed. During the following year this opinion was confirmed by a rebellious cough, occasional spitting of blood and pus, fever and other symptoms indicating possible tuberculous infection, although the apices were normal. Seventeen months after the primary vomica the patient coughed up a bunch of "membranes and skin and something that looked like strips of tripe." From this moment all symptoms ceased, and the cure has been radical and permanent.

Diffuse Symmetrical Lipomatosis. C. Pestemazoglu.—Two cases are described, and one illustrated, showing the large symmetrical lipomatous masses above the nipples, front and back, and on the median line above, also on the neck. One of the patients had been operated on a few years before and had had a large interscapular lipoma removed. They begged to be relieved of their encumbrances, and five of the masses were removed from one patient. They were not encapsulated, and it was impossible to make the operation complete, as the fat extended behind the muscles, etc. The presternal mass had already commenced to grow again two months after the operation.

Progres Medical (Paris), August 25.

Graft of Severed Terminal Phalanx of Thumb. Salomon.—In a number of cases in which the end of a thumb or finger had been totally severed, Salomon failed to obtain complete restoration of the severed portion until he commenced to use asepsis instead of antisepsis. Since then he has had invariable success, even when a large portion of the finger had been lost. He first keeps the hand for three-quarters of an hour immersed in very hot sterilized water, occasionally renewed, to which a little alcohol has been added. Four catgut stitches then hold the severed portion in place and the finger is packed in cotton.

Semaine Medicale (Paris), August 29.

Overlapping of Auricular and Ventricular Systoles. Potain.—The propulsion produced at the apex during the moment preceding the closing of the auriculo-ventricular valves, and the first bruit is attributed by Potain to the distension of the ventricle by the systole of the auricle. Others ascribe it to the systole of the ventricle itself, and Bard has recently announced that it is due to the overlapping of the systoles, the ventricular systole anticipating the end of the auricular systole, causing what he calls the "*chevauchement des systoles.*" It is due, he believes, to the resistance to the closing of the mitral valve on the part of the hypertrophied auricle. He states that palpation reveals a characteristic hardness at the precordial region just before the closing of the valves, which indicates a contraction of the ventricle—an active and not a passive phenomenon. It does seem as if this "dome shock" were too considerable to be attributed to the contraction of the "despised" auricle alone, as Potain admits. He observes that if he trusted to his impressions alone he would be dubious, but that the Marey instruments positively establish that the true début of the ventricular systole and the true first bruit are synchronous; that the presystolic thrill is a direct result and a sign of mitral stenosis, and that—in spite of appearances to the contrary and his personal impressions—he is convinced that the "choc en dome" is a phenomenon of auricular origin.

Centralbatt f. Chirurgie (Leipsic), August 25 and September 1.

Thermorphor With Ether Mask. Longard.—The ether mask described by this author in the Centralblatt, No. 48, 1898, was found to have the disadvantage that the air condensed inside and ice crystals were liable to form from the evaporation of the ether. This is obviated by a ring-shaped thermophor made to fit around the edge between the netting and the cover, which keeps the temperature considerably above the freezing-point.

Rattan Splints. H. Sarfert.—Wicker-work splints have been found desirable from every point of view by Sarfert, who recommends them on account of their lightness, durability, inexpensiveness, elasticity and porosity for military, general hospital and emergency use.

September 1.

Plastic Restoration of Lower Jaw. W. Sykoff.—A chin was restored after an extensive defect consecutive to noma, by cutting a rectangular piece out of the largest side of the lower maxillary bone and slipping it along to bridge the defect, the farther end resting in a groove hollowed out for it in the other half of the bone. The results were highly satisfactory. A fragment of rib, with the periosteum, would probably have done equally well.

Deutsche Medicinische Wochenschrift (Leipsic), August 30.

Queirolo's Method of Outlining the Stomach. P. Edel.—Comparison of the findings with Queirolo's method and with the other methods in vogue shows that they are identical in the results attained. The former may prove useful at times as a supplementary measure, but in general, inflating the stomach with CO_2 generated by tartaric acid and sodium bicarbonate is sufficient and reliable. Queirolo introduces a sound into the stomach, the lower end of which is inserted in a small bladder. The sound communicates above with a two-branched rubber tube. One branch connects with a Marey drum, the other with the outer air, and through it the bladder is inflated. Percussion over the abdomen does not stir the index, but the moment the limits of the stomach are reached the drum records it at once. The organ can thus be outlined with comparatively little trouble. In one case of stenosis of the pylorus it was impossible to locate the stomach limits by any other method. Percussion is not reliable with an entirely empty stomach. Air or fluid is necessary for the test.

Differentiation of Aneurysms With Radiography. E. Gebauer.—A patient in Grawitz's service, with evidences of an intrathoracic tumor or aneurysm of the aorta, showed on the fluorescent screen a distinctly pulsating tumor just above the heart. The diagnosis of aneurysm of the aorta was made, but the autopsy disclosed a carcinoma of the esophagus, with perforation into the lung, and metastases above. The left bronchus had become adherent to the arch of the aorta, inducing Oliver's sign. The simulated pulsation must have been caused by the rising of the metastatic tumor with the systole of the aorta, and the sidewise movement of the primary tumor with the systole of the descending aorta, to which it was adherent.

Diphtheritic Vulvo-Vaginitis. L. Silberstein.—A case was reported in 1898 of gangrenous vulvo-vaginitis cured with diphtheria antitoxin. It proved equally effectual in the case described in this communication. Two injections of 1000 units were made, it being known that the patient, a child of 4½ years, had been exposed to diphtheria.

Muenchener Medicinische Wochenschrift, August 28.

Significance of the Diazo-Reaction in Tuberculosis. P. F. Becker.—A positive reaction to the diazo test is not necessarily of serious import. It [illegible] in tuberculous subjects in connection with [illegible] complication such as diarrhea, and positive reaction should not be accepted as evidence of a grave prognosis under all circumstances. When it occurs in a disease not usually accompanied by it a complication of an infectious character may be assumed. Certain cases respond with a dubious reaction to the test. The green color is most intense in these dubious cases when positive, but there is a slight greenish tint even with a negative reaction.

Acute Osteomyelitis of the Atlas. Eichel.—Two cases are described in detail, the diagnosis based on the pains, increased by jolting in a wagon or car, the attitude of the head and the neuralgic pains, in one case in the region of the supraorbital nerve. Temperature 38.4 C. Eichel observes that with these symptoms and swelling of the back of the neck, he would operate without waiting for fluctuation, in order to forestall perforation of the pus into the spinal canal. In case tuberculous alterations are discovered he suspends the operation at once and resorts to immobilization and extension as usual, but would not allow the possibility of this contingency to deter him from operating.

Joint and Cutaneous Metastases With Blenorrhea Neonatorum. J. Paulsen.—Pure gonococcus metastases occurred in the joints of a 2-months babe, consecutive to gonorrheal ophthalmia. The skin around the affected joints became edematous, and finally exanthemata appeared, evidently due to invasion from the deeper tissues. One knee required operation and the gonococcus was found pure in the pus and in the surrounding exanthem. Complete restitution was obtained.

Tetanus and Intestinal Occlusion. Krey.—No serum was given in the severe case of traumatic tetanus reported. The case was complicated by acute occlusion from intussusception of the small intestine, requiring laparotomy. The tetanus continued its course for two weeks longer, and then gradually subsided.

Virchow's Archiv f. Path. Anat. (Berlin), July 7.

Criticism of Koch's Malarial Research. J. H. F. Kohlbrugge.—The author of this communication is privat docent of climatology and tropical diseases at Utrecht, and practiced medicine for many years in Java. He claims that Koch's assertions in regard to the immunity against malaria probably acquired in time by natives and foreigners contradict the experience of all practitioners in tropical countries. The longer the residence the more severe the attacks, as a rule. The weak die off and those who survive—of either native children or imported foreigners—are the congenitally more resistant, the élite of more or less naturally immune individuals. He also objects to Koch's deductions that because apes—"the animals closest to man"—proved refractory to malarial inoculations, it is scarcely probable that other animals will prove susceptible. Anthropoids, he points out, are far less close to man, toxicologically at least, than a number of other animals, especially dogs. He asks why Koch did not go to some true malaria-infested district in Java, such as the Djoewana coast, with its 222,000 inhabitants. The report from this district for 1899 stated that 22,000 persons were "down with malaria and the people are dying like rats." Practically the same report is received each year. The population scarcely changes, and it is evident that no immunity has been acquired. The *Deutsche Med. Wochenschrift*, which has published Koch's reports to the Imperial Health Bureau, has refused to insert this or Nuttall's critical articles in Koch's absence.

Wiener Klinische Rundschau, August 26.

Death After Resection of Jugular Vein. C. Ewald.—While a patient in Albert's clinic was having the pharynx and tongue resected, it was found necessary to resect the internal jugular vein on both sides. There was an anastomosis between the internal and anterior jugular veins on one side. The patient had been operated on in a half-sitting posture, and the operation lasted from thirty to forty-five minutes longer. When raised erect to apply the bandages he became cyanotic, but soon recovered. Placed in bed on an inclined plane—head downward—to prevent aspiration of the secretions, the pulse and respiration were normal, but in half an hour he became blue, and raising him erect had no effect. The color gradually returned to normal, but the heart action became weaker and, in spite of artificial respiration and other measures, death ensued in an hour. The face and trunk had become so pale that an internal hemorrhage was surmised, but none was discovered. The dura mater was found pale and the longitudinal sinus empty. The vena cava, portal vein and the viscera were gorged with blood, the heart in fatty degeneration. The brain was edematous and anemic. Ewald attributes the fatal termination to vasomotor disturbances. The cyanosis occasionally noted after resection of both internal jugular veins usually passes away spontaneously in a few days.

Transplantation of Flaps for Atresia Vaginae. S. G. Schalita.—The disadvantages of the usual methods of making a new vagina or curing defects are obviated by the method described by Schalita. He hollows out the passage and dilates it with a speculum for a day or so. Then he inserts a speculum with large fenestræ and applies flaps of mucous membrane taken from the labia or elsewhere to the exposed portions of the vaginal wall. A second plain speculum, a size smaller than the other, is introduced inside the first, to prevent the protrusion of the walls through the opening. Both are left undisturbed for a time and then replaced with a simple speculum. In a case described, the epithelium proliferated in all directions from the flaps, which, with scarcely an exception, healed perfectly in place.

Phosphorus Necrosis. J. Levai.—The arguments presented by Levai demonstrate that the necrosis of the bones in consequence of chronic intoxication with phosphorus is caused primarily by pathologic alterations in the vessels. The direct occasion of the necrosis is some external cause, usually an infection.

Wiener Klinische Wochenschrift, August 30.

Pathogenesis of Icterus. Browicz.—This communication summarizes the results of extensive clinical and experimental research, and was read at the Polish Medical Congress which met at Cracow, July 23. It attributes icterus to an increased functional activity of the normal liver cells, which, under the stimulus of various influences, take up immoderate quantities of food and function-material, especially hemoglobin, and work it over into an excessive output of bile, and of bile-pigment in particular. This excess of bile can be produced only by a normally active, healthy liver cell. The surplus secretion of bile passes into the intercellular biliary passages and is thence absorbed through the walls of the blood capillaries in the acini into the circulation. There is much less proportional absorption through the lymph vessels in the larger biliary passages. This conception of the increased function of normal liver cells and immoderate production of bile explains all varieties of icterus, even the most apparently diverse.

St. Petersburger Medicinische Wochenschrift, August 23.

Acute Polyarthritis Consecutive to Angina Lacunaris. Woloshintsky.—The parents, six children and the cook in a family in Riga passed through a house epidemic of angina lacunaris, and in three of the members acute or subacute articular rheumatism developed in three to six days. The author also had occasion to treat four cases of abortive acute articular rheumatism last year, occurring two to six days after the commencement of a typical angina lacunaris. He ranks the latter as an essential, morbid entity, with general and local symptoms, entirely distinct from the angina of scarlet fever, etc. Pyogenic cocci are always found in it. The joints may be the seat of suppurative processes in genuine articular rheumatism and the clinical picture of pyemia be superposed. In the same way, on the other hand, pure pyemic processes may appear simulating polyarthritis, and it is difficult, even at the autopsy, to determine the primary affection. The frequent complication of erysipelas with polyarthritis supports the assumption of the pyogenic etiology of articular rheumatism.

Anales de Oftalmologia (Mexico), August.

Experimental Study of the Minimum Visual Angle. P. De Obarrio.—In an attempt to repeat and control Wuelfing's experiments and determine the influence of colors on the appreciation of the minimum angle, Obarrio has learned that the minimum visual angle is much smaller than we have been accustomed to assume hitherto, also that the use of colors has no influence on the appreciation of this angle.

Change of Address.

L. C. Bacon, 556 Selby Ave., to 737 Fairmount St., St. Paul, Minn.

R. G. Barnsdale, 420 Main St., Stevens Point, to West Superior, Wis.

E. W. Baum, 3200 Wallace St., to 1129 Lill Ave., Chicago.

C. M. Beall, 1469, to 1259 Kenesaw Ave., Washington, D. C.

Maxwell Benjamin, 196 Alex. Ave., to 30 W. 126th St., New York City.

C. Bock, Petoskey, Mich., to Ft. Wayne, Ind.

Carl Booth, Barnes Medical College, to 3202 Pine St., St. Louis, Mo.

B. J. Callahan, Humboldt, to 521 Locust St., Des Moines, Iowa.

Julia W. Carpenter, Rock Ridge, Watch Hill, R. I., to 908 E. McMillan St., Cincinnati, Ohio.

G. W. Drake, Monteagle, Tenn., to Hollins, Va.

C. M. Dumm, 540 Shaw Ave., McKeesport, to Allegheny County Home, Woodville, Pa.

J. W. Duncan, Gay and Vine Sts., Knoxville, Tenn., to 101½ Whitehall St., Atlanta, Ga.

J. M. Eisenbise, Lawrence, to Fairview, Kan.

W. W. Fugitt, Denton, to Burtonville, Ky.

Elizabeth White, St. Luke's Hospital, New York City, to Romney, W. Va.

L. D. Wilson, 12th St., to 1132 Chapline St., Wheeling, W. Va.

C. W. Womack, Tullahoma, Tenn., to S. A. F., College, San Antonio, Tex.

H. A. Wright, Linkville, Ore., to Wilbur, Wash.

Queries and Minor Notes.

ANXIOUS TO BE A QUACK.

The following is clipped from a Chicago newspaper; the last qualification, certainly, ought to get the position desired:

Situation Wanted—By physician with an advertising specialist; competent to conduct correspondence, hold the chair, and good feetaker.

COMMISSION TO OPHTHALMIC SURGEONS.

Atlanta, Ga., Sept. 14, 1900.

To the Editor:—Six years ago, when I began the practice of ophthalmology in this city, the leading optical house approached me with the proposition that if I would send to them all of my prescription work they would allow me one-third of the amount paid them by the patient on each prescription, and at the end of the month send me a check on this basis for the number of prescriptions received. I immediately declined such an offer on the grounds that it was dishonest to make the patient pay me twice; rather preferring the reduction should be made in favor of the patient at the time of purchasing the glasses. This rule I have strictly adhered to, although the opticians will not give this reduction to the purchaser, claiming that they cannot afford to have two prices for customers. This same optical house has recently told me that such a contract between oculist and optician is practiced in all the large cities, as New York and Chicago, and this, too, by the leading men in the profession. I should certainly like to know the truth of this statement and whether such practices *are considered ethical* Dunbar Roy.

Ans.—The above query was submitted to Dr. Casey A. Wood, editor of the *Ophthalmic Record*, who sends the following reply:

"Dr. Dunbar Roy's query may, so far as it relates to the city of Chicago, be safely answered in the negative. It is not a common practice for the optician to pay the ophthalmic surgeon a commission on glasses furnished by him, nor would such a practice be considered ethical. I believe I am voicing the sentiment of the profession in this city when I say that such a doubtful method could not be generally practiced and be long kept a secret. A number of perfectly reputable ophthalmologists furnish glasses to their patients just as certain other physicians dispense their own drugs, and doubtless there are arguments that may be advanced in favor of this plan, but I am not acquainted with a single confrère who is willing to defend the practice of accepting commissions from the optician. If one exists, Dr. Roy's note furnishes *an excellent opportunity for him to come forward and show cause* for such conduct. Casey A. Wood, M.D."

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., August 29 to September 4, 1900, inclusive:

William F. Bernart, acting asst.-surgeon, relieved from duty at the Army and Navy General Hospital, Hot Springs, Ark., for annulment of contract.

George M. Bradfield, acting asst.-surgeon, previous orders revoked; on being relieved by Acting Asst.-Surgeon Harold W. Cowper, he will proceed to Philadelphia, Pa., for annulment of contract.

Henry R. Carter, jr., acting asst.-surgeon, relieved from the Department of the Columbia for assignment with troops going on foreign service.

Harold W. Cowper, acting asst.-surgeon, from the Department of Porto Rico to Fort Ontario, N. Y., to relieve Acting Asst.-Surgeon Bradfield.

Joseph J. Curry, acting asst.-surgeon, now at Zanesville, Ohio, on the expiration of his present sick leave to duty at the Army and Navy General Hospital, Hot Springs, Ark.

Orlando Ducker, major and surgeon, U. S. Vols., honorably discharged from service, to take effect September 30, 1900.

Thomas G. Holmes, acting asst.-surgeon, from Fort Wright, Wash., to acompany Cops. "B" and "M," 24th U. S. Infantry, to Manila, P. I.

David J. Johnson, acting asst.-surgeon, previous orders revoked.

Henry S. Kilbourne, major and surgeon, U. S. A., member of a board to prepare a comprehensive plan for the location of new buildings, roads and walks at Fort Hamilton, N. Y.

Elmer E. Mansfield, acting asst.-surgeon, from Wilmer to San Antonio, Tex., for duty with the 25th U. S. Infantry under orders for foreign service.

William E. Richards, lieutenant and asst.-surgeon, U. S. A., previous orders revoked; leave of absence granted.

William J. S. Stewart, acting asst.-surgeon, from Vineyard Haven, Mass., to Fort Slocum, N. Y., to accompany recruits to the Philippine Islands.

Charles K. Winne, major and surgeon, U. S. A., from Fort Crook, Nebr., to duty at Fort Porter, N. Y.

Marshall W. Wood, major and surgeon, U. S. A., leave of absence granted.

The following acting assistant-surgeons have been directed to proceed from the places designated to San Franciscl, Cal., for assignment to duty with troops destined for foreign service: Charles L. Baker, Duffield, West Va.; John L. Burkart, Grand Rapids, Mich.; Max F. Clausius, Barrington, Ill.; Samuel C. Lindsay, Salineville, Ohio; Irvine W. Patton, Huntsville, Ala.; George M. Ekwurzel, Philadelphia, Pa.; Charles A. Ross, Leopold, Ind.; Charles R. Reynolds, Philadelphia, Pa.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Sept. 8, 1900:

Asst.-Surgeon E. V. Armstrong, granted sick leave for one month.

P. A. Surgeon C. M. DeValin, ordered to additional duty at the navy yard, Portsmouth, N. H.

Asst.-Surgeon A. G. Grunwell, detached from the *Monocacy* and ordered to the *Brooklyn* by commander-in-chief of Asiatic Station.

Asst.-Surgeon T. M. Lippitt, detached from the *Newark* and ordered to the *Monocacy*.

Surgeon A. C. H. Russell, detached from the naval hospital, Yokohama, Japan, and ordered to proceed home and to wait orders.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commisioned officers for the U. S. Marine-Hospital service for the seven days ending Sept. 6, 1900:

Surgeon D. A. Carmichael, detailed as chief quarantine officer Territory of Hawaii.

Surgeon J. H. White, to proceed to New York City, for special temporary duty.

P. A. Surgeon A. R. Thomas, relieved from duty at London, England, and assigned to duty in the office of the U. S. consul at Glasgow, Scotland.

Asst.-Surgeon C. H. Lavinder, detailed as chief quarantine officer of Porto Rico.

Asst.-Surgeon J. F., Anderson, relieved from duty at Vienna, Austria, and assigned to duty in the office of the U. S. Consul-General at London, England.

Asst.-Surgeon J. W. Kerr, relieved from duty at Honolulu, H. I., and directed to proceed to Hongkong, China, for duty in the office of the U. S. consul.

Asst.-Surgeon G. M. Corput, granted five days' extension of leave of absence.

Hospital Steward E. S. Maguire, upon being relieved by Hospital Steward Charles Miller, to proceed to Fort Stanton, N. M., and report to medical officer in command for duty and assignment to quarters.

Hospital Steward Charles Miller, relieved from duty at Detroit, Mich., and directed to proceed to New York (Stapleton) and report to medical officer in command for duty and assignment to quarters.

Hospital Steward C. H. Woods, relieved from duty at Cairo, Ill., and directed to proceed to Chicago, Ill., and report to medical officer in command for duty and assignment to quarters.

Hospital Steward H. V. LaGrange, on expiration of leave of absence relieved from duty at Fort Stanton, N. M., and directed to proceed to Cairo, Ill., and report to medical officer in command for duty and assignment to quarters.

Hospital Steward Edward Rogers, upon being relieved by Hospital Steward C. H. Woods, to proceed to Detroit, Mich., and report to medical officer in command for duty and assignment to quarters.

Hospital Steward Mark H. Watters, directed to report to medical officer in command at Chicago, Ill., for temporary duty and assignment to quarters.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Sept. 8, 1900:

SMALLPOX—UNITED STATES

Alaska: Nome, Aug. 11, 6 cases.

Louisiana: New Orleans, Aug. 25-Sept. 1, 4 cases, 1 death.

Minnesota: Minneapolis, Aug. 18-25, 2 cases; Winona, Aug. 21-28, 2 cases.

Ohio: Cleveland, Aug. 26-Sept. 1, 9 cases; Portsmouth, Aug. 26-Sept. 1, 3 cases.

Utah: Salt Lake City, Aug. 19-Sept. 1, 4 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Aug. 11-18, 1 case.

Brazil: Pernambuco, July 1-15, 1 death.

England: Liverpool, Aug. 11-18, 2 cases.

France: Paris, Aug. 5-18, 5 deaths.

Gibraltar: Aug. 12-19, 1 case.

India: Calcutta, July 28-Aug. 4, 10 deaths; Madras, July 28-Aug. 3, 2 deaths.

Japan: Formosa, June 1-30, 39 cases, 3 deaths.

Mexico: City of Mexico, Aug. 19-26, 8 cases, 1 death; Vera Cruz, Aug. 19-Sept. 1, 2 deaths.

Russia: Moscow, Aug. 5-11, 4 cases; Odessa, Aug. 11-18, 8 cases, 5 deaths; Warsaw, Aug. 4-11, 6 deaths.

Scotland: Dundee, Aug. 19-25, 1 case; Glasgow, Aug. 17-24, 28 cases.

Spain: Corunna, Aug. 11-18, 1 death; Madrid, July 28-Aug. 11, 63 deaths.

YELLOW FEVER

Colombia: Bocas del Toro, Sept. 1, 1 case; Cartagena, Aug. 3-17, 3 cases, 3 deaths; Panama, Aug. 20-27, 3 cases, 1 death.

Cuba: Batabona, Aug. 18-25, 1 case; Havana, Aug. 15-20, 9 cases.

Mexico: City of Mexico, Aug. 19-26, 1 death; Vera Cruz, Aug. 19-Sept. 1, 23 deaths.

West Africa: Dakar, Aug. 15, 14 cases; St. Louis, Aug. 15, 24 cases, 2 deaths.

CHOLERA

India: Calcutta, July 28-Aug. 4, 18 deaths; Madras, July 27-Aug. 3, 13 deaths.

Japan: Yokohama, July 28-Aug. 4, 1 case.

PLAGUE

China: Amoy, July 7-28, 1150 deaths; Hongkong, July 14-28, 78 deaths.

India: Calcutta, July 28-Aug. 4, 41 deaths.

Japan: Formosa, June 1-July 26, 167 cases, 135 deaths.

Philippines: Manila, July 10-17, 1 death.

Straits Settlements: Singapore, July 14-21, 1 death.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that *they are contributed solely to this journal.*

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Original Articles.

TECHNIQUE OF VAGINAL EXTIRPATION FOR CANCER OF THE CERVIX BY LIGATURE ONLY*

RUFUS B. HALL, A.M., M.D.
CINCINNATI, OHIO.

It would hardly seem necessary before this audience to emphasize the importance of careful preparation of the patient before subjecting her to such a serious operation as the one to be considered. Yet this is a very important element in the after-management and in bringing a case of hysterectomy for cancer to a successful termination. These patients should be as carefully prepared for the operation as though they were about to be subjected to an abdominal section. It is especially desirous that the function of the kidneys be carefully investigated in every instance and every defect noted and corrected if possible. It is always advantageous in this preliminary treatment to keep the patient under observation for a few days.

The anesthetic selected should be chloroform in every instance, unless it is contraindicated from heart lesions, or, as is the case in rare instances, where the patient does not take the chloroform kindly. Then ether should be substituted.

The extreme lithotomy position should be used. The perineum should be retracted by a short, broad speculum. An instrument with a blade an inch and three-quarters long and an inch and a half to two inches broad is to be preferred, with such other retractors as the operator may deem necessary. The writer uses one or two narrow short-beaked retractors.

If the disease in the cervix is a large sloughing mass with or without severe hemorrhage, or if it is an epithelioma filling the upper half of the vagina, it is advantageous to do the operation in two stages. First, give an anesthetic and with a sharp curette cut away all of the soft tissue, and then with a thermocautery cauterize deeply all the raw surface. Postpone the radical operation for ten days or two weeks. At this time it will be found that there is an apparently healthy granulating surface, greatly contracted, and with none of that disagreeable stench which is always present in the condition just described. By this plan there will be less danger of infection. If the case is one that has recently lost much blood and still continues to bleed, this will stop the bleeding and give time to recuperate her strength somewhat. If it is proposed to do the radical operation the patient should be properly prepared and anesthetized, and then placed in the lithotomy position with the "clover crutch" applied. There should be an assistant standing at each side of the patient to steady the limbs and assist in holding the retractors, instruments, etc. The vagina should be thoroughly cleansed, the sharp curette again used and all the soft tissue cut away. The uterus should be curetted when indicated. The raw surface should again be cauterized with the thermocautery, and the vagina again thoroughly cleansed and irrigated with a 1 to 1000 solution of bichlorid of mercury.

It has been asserted with great positiveness by Cheyne and others that in operations for cancer, where the operator is compelled to cut through the cancerous tissue, there is great danger of disseminating cancerous cells over healthy tissue in the subsequent steps of the operation. This is the probable cause of recurrence later in a great many instances. Whether we accept this view or not, the thorough curetting and subsequent cauterizing, by preventing infection, adds to the safety of the patient. This also prevents bringing the cancerous tissue in contact with the healthy tissues in the subsequent steps of the radical operation.

The cervix should be fixed with a strong vulsellum forceps. The vaginal mucous membrane should be divided clear around the cervix with a knife or scissors. It should be divided a good, safe distance from the diseased area, usually a half inch or more, as indicated by the extension of the disease, and this cuff-like piece of mucous membrane then dissected back to its attachment to the uterus. This can be readily done by blunt dissection, with an occasional nick with the scissors. The bladder is detached from the uterus and the peritoneal cavity opened in front. The right and left index fingers are placed in the wound and widely separated. This part of the operation should be carefully carried out so as to push the ureters with the adjacent tissues far aside. As soon as this has been accomplished, a gauze pad $3\frac{1}{2}$ by 5 inches, with a stout ligature attached, is passed into the peritoneal cavity and left resting on the uterus. The peritoneal cavity is again opened behind the uterus and the tissues pushed laterally as far as possible. The uterus now remains attached to the broad ligaments only. The operator places his first ligature at this stage of the operation. This should be a very heavy silk twist and the same material used for all the ligatures. The writer usually uses the Cleveland ligature-carrier for this purpose. He has a trusted assistant sitting to his left, whose duty it is to place the ligature in the carrier.

If the disease is more marked on one side of the uterus than it is on the other, which is usually true, he selects the healthy side for his first ligature. This is tied tightly, including a bite of tissue not thicker than a lead pencil. When the knot is thoroughly secured the tissue included is divided, leaving a good button of tissue to prevent slipping of the ligature, and one end cut short. If the disease is not far advanced, a ligature can be placed on the opposite side and treated likewise.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

This can be repeated, going from one side to the other alternately, the uterus gradually descending, until the operator is able to pass a ligature over the top of the broad ligament on one side. For this maneuver the Rickett's ligature-carrier is the best I have seen. Every ligature must be tied as carefully as though the operator expected to secure one of the main arteries in its bite. This is the only way to insure perfect hemostasis. It is important not to secure too large a bite of tissue in any one ligature. As soon as one broad ligament has been divided, the uterus can be turned aside and brought out of the vagina. Then the remaining broad ligament can be ligated from above and the ligature placed outside of the ovary and tube. This is important from the fact that the tubes are favorite channels for the extension of malignant disease. Therefore the tubes and ovaries should always be removed in cancer of the uterus. It is not always possible to place the ligature outside of the ovary and tube before the first broad ligament is divided, but after the uterus has been removed, as indicated, the operator can readily place a second ligature beyond the ovary and tube of the first broad ligament divided, and remove them. In this operation there will frequently, in fact, usually, be from six to ten ligatures on either side. The operation is almost a bloodless one. It is very unusual indeed for a patient to lose more than an ounce or two of blood.

The gauze pads placed early in the operation come into view now. They serve to protect the intestines and omentum and to prevent them from coming into the field of operation. They also absorb any blood that is lost during the operation. The bunch of ligatures on either side are now secured by tying one of the ligatures around the rest on that side, and are given into the care of the assistant. The peritoneal edges of the wound are united at the pelvic brim above the ligatures in the following manner:

A Hagedorn needle is threaded with catgut and passed through the anterior flap of the peritoneum near the angle. It then catches up the peritoneum on the broad ligament half an inch beyond the last ligature, then again catches up the peritoneum on the posterior wall near the angle. The ligature is then knotted. This brings peritoneum to peritoneum beyond the topmost ligature. This stitch is continued from one peritoneal flap to another in a running suture until the middle line is reached, then it is drawn taut. This ligature is given into the hands of an assistant. A like maneuver is carried out on the opposite side, except that the ligature is not drawn taut until after the gauze pads are removed. The gauze sponges are removed from the peritoneal cavity, and with a bit of gauze in the bite of a forceps the blood, if any, is removed from the pelvic cavity. By pulling on the ends of the catgut ligatures the peritoneum is nicely adjusted throughout from one pelvic brim to the other, but not so tightly that the blood can not escape from the pelvis for the first few hours. The two ends of the catgut are in apposition in the middle line, and are knotted and cut short. The vagina is packed snugly with iodoform gauze resting against the peritoneum. This is not disturbed for four days, during which time the patient is catheterized as occasion may require. The gauze is removed on the fourth day and not replaced, and the patient is given a hot vaginal douche. This is repeated at short intervals and she is permitted to void her urine.

The use of the ligature in this operation in place of the clamp is a distinct advance in surgery and should always be preferred. There is less suffering and an easier convalescence. In the operation with the ligature, if the disease is far advanced on one side, the operator can place the ligatures on the healthy side until he divides the broad ligament and turns the uterus out of the vagina. He can then work from above downward and enucleate the indurated cancerous tissue far out into the broad ligament. This maneuver would be totally impossible by the clamp method. The writer has performed this feat on a number of occasions and has been surprised at the ease with which it was accomplished on cases that would have to be refused operation by the clamp method, or the operator would be compelled to leave the cancerous tissue in the broad ligament.

The danger of dividing the ureters is always present, but the writer does not believe that it is always necessary to pass a bougie into the ureter. By opening the peritoneal cavity freely in front and pressing the tissues and ureters far from the middle line, with ordinary care, it would be rare indeed that a ureter would be ligated or divided in a case that should legitimately be operated on for cancer.

One of the great advantages in operating with the ligature is the fact that the peritoneum can be closed as accurately after the operation as in a median section. This is thoroughly closed by plastic exudation long before pus is formed, thus closing the cavity from danger of infection. If the gauze packing is allowed to remain three or four days, the peritoneum will be thoroughly united and the danger of infection and subsequent intestinal obstruction will be very small. Not a single case of infection or obstruction has occurred in something over 100 operations made by the writer.

ABDOMINAL VS. VAGINAL HYSTERECTOMY FOR UTERINE CARCINOMA.*

JOHN B. DEAVER, M.D.
SURGEON-IN-CHIEF OF THE GERMAN HOSPITAL.
PHILADELPHIA.

The choice of route for hysterectomy must be selected for each case. It is my desire to present a concise résumé of the reasons for each, and the advantages they offer in the cases to which they are applicable.

The views laid down are those of the general surgeon, and are based on an experience in this work that justifies, I think, an opinion. It has been claimed that vaginal hysterectomy is an operation that requires special training and attention to detail and technique which can only be acquired by the specialist. I can not, however, allow this statement to go unchallenged, for I believe that the general surgeon, with his larger field and constant application to detailed technique, is equally well, if not better, equipped to perform every operation of gynecology than is the specialist himself.

Who to-day, but in exceptional instances, would dream of amputating a carcinomatous mammary gland and leave *in situ* the axillary chains of lymphatics whether they be macroscopically infected or not, and yet how many of the leaders of gynecology recommend or perform themselves the complete operation for carcinoma of the uterus? Carcinoma of the uterus is a very common disease, not more so to-day than formerly, but with increased knowledge and diagnostic skill we are able to discover and remove, in good time, uteri that otherwise would soon end in the destruction of the patient.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

I favor and perform abdominal hysterectomy for the great majority of cases of uterine carcinoma, although I grant there are cases where the vaginal operation may be the better. That the vaginal operation offers any advantages over the abdominal route is with me a question. I know of no condition indicating vaginal hysterectomy which possibly can not be better dealt with by the abdominal route.

For the sake of clearness and logical reasoning I propose to take up the different points for discussion in the order laid down in the synopsis in the ASSOCIATION program.

REMOVAL OF THE PELVIC GLANDS.

For the purpose of refreshing our memory I will give a brief account of the lymphatic glands and their connecting channels which are involved in the morbid processes of the uterus. The superficial lymphatics of the uterus, together with those of the ovaries and the Fallopian tubes, empty into the lumbar glands. They lie beneath the peritoneum and are joined by those from the substance of the fundus and the upper portion of the body of the organ; together they run outward, in the broad ligament, when they are joined by the lymphatics from the ovaries, Fallopian tubes and vagina to pass up with the ovarian vessels to the lumbar glands. The lymphatics from the lower part of the uterus and from the cervix of the uterus run together with most of the lymphatics of the vagina along the course of the uterine and vaginal vessels, and terminate in the internal iliac glands. The lymphatics from the lower part of the vagina join the superficial inguinal glands.

We therefore have two chains of lymphatics to consider, and while the chains nearest the disease are probably engaged in draining the part, it is not unusual to have both the upper and lower chains on one or both sides involved, necessitating their removal, if we wish to give the patient the only possible hope of recovery.

In late carcinoma or even in the early stage of rapidly advancing disease, if there is macroscopical involvement of the broad ligament, any operation short of total extirpation of the lymphatics of the pelvic organs had better not be attempted.

The abdominal operation offers the only way by which we can perform a complete hysterectomy. The incision must be a long one, the intestines and omentum kept away from the field of operation by gauze packing, the wound widely retracted, and the light good in order to perform so delicate and intricate an operation.

BETTER AREA FOR COMPLETE EXTIRPATION OF CARCINOMATOUS TISSUE.

The reasons given for the first heading hold good for the second. I can not conceive of skill so great which would make a dissection of a carcinomatous broad ligament as easy or as complete through the vagina as by the abdominal route.

LESSENED DANGER TO URETERS.

The weak spot of vaginal hysterectomy has always been the danger of injury to the ureters. As a matter of fact the ureters are in danger of injury by either route, but it seems to me that the danger is less by the abdominal route, for the evident reason that one can see what he is doing and is therefore better enabled to protect these important structures. Granting that either ureter has been torn in the removal of the carcinomatous uterus, the repairing must be done through an abdominal incision, and if it has happened in the course of a vaginal hysterectomy the abdomen must therefore be opened.

CATHETERIZATION OF URETERS UNNECESSARY.

It has been recommended by some of the advocates of vaginal hysterectomy that the ureters should be catheterized as a preliminary step. If for no other reason than this I prefer the abdominal route. From unpublished evidence which I have been able to collect, this step of the operation of catheterization of the ureters is almost as frequently a failure as a success. This uncertainty, combined with the actual danger of kidney infection and the injury of the urethra from over-stretching, is a strong argument to me against the vaginal route. I can not, however, grant that catheterization of the ureters is an essential part of vaginal hysterectomy.

Where the broad ligaments are involved in the carcinomatous process, if only to the degree of being slightly rigid, it is extremely difficult, if not impossible, to make out the ureters. Under these circumstances catheterization would be wise were it not for the fact that such cases, if not attacked through the abdomen, had better be left alone, as incomplete operation offers nothing to the patient, in fact hastens the progress of the disease.

LESSENED DANGER OF HEMORRHAGE.

There is undoubtedly greater danger of hemorrhage in vaginal hysterectomy for carcinoma of the uterus, although hemorrhage is liable to occur in either operaiton on account of distorted, displaced or degenerated vessels. *It is simply a matter of increased facility* for seeing the locality of hemorrhage that gives the advantage to the abdominal method. In vaginal hysterectomy we are working at the bottom of a dark passageway, and when, in addition to this, the field of operation is covered with blood, any accuracy in manipulation is out of the question. Ligation of the ovarian and uterine arteries is a very simple matter in abdominal hysterectomy for uterine carcinoma on account of the ease with which the site of operation can be exposed.

CONSECUTIVE HEMORRHAGE LESS LIABLE TO OCCUR.

The better command of the field of operation secured by the abdominal route makes the placing of the ligatures on the vessels so much more accurate and secure that consecutive hemorrhage is not only less liable to occur, but as a matter of fact is a very rare accident. When it does occur we can with good reason suspect the ligature material or carelessness.

DANGER OF INFECTING PERITONEUM LESSENED.

The use of the Trendelenburg position, with occlusion of the general peritoneal cavity and its contents by gauze packing, minimizes the risk of infection.

In vaginal hysterectomy the intestines are liable to come in contact with the fingers, instruments, ligatures, etc., which have traversed the vagina, that, in cases of carcinoma, or in any inflammatory or infectious disease, is never rendered sterile. In fact, I have very serious doubts as to the sterilization of any vagina. It is claimed that the upper portion is normally sterile, but a vagina which is patulous and which is not virgin, is, so far as I know, a fertile soil for pathologic organisms, although they remain inactive, pathologically speaking, until circumstances arise favoring activity.

Under this heading comes the question of drainage. I believe that most of the cases of abdominal hysterectomy should not be drained. When, however, drainage is needed it should be supravaginal. Vaginal hysterectomies call for gauze drainage in all cases.

NO DANGER OF PROLAPSING BOWEL.

In total removal of the uterus, be it by the vaginal or abdominal route, there is danger of prolapsing bowel, but by the more perfect closure of the peritoneum from above, the danger is lessened in the latter method. The abdominal incision makes a subsequent ventral hernia a possibility to be considered, but with the combination of the interrupted and the tier or layer suture and careful approximation of muscle to muscle, the danger is practically nil.

Vaginal hysterectomy is an operation which presents no special difficulties in the class of cases to which it is applicable. It is only applicable in those cases where the carcinomatous process is strictly confined to the vaginal portion of the cervix, the cervical or uterine canal, and where the uterus is freely movable. In cases where there are adhesions fixing the organ, or where there is or has been inflammation or fixation of the appendages, the abdominal operation is safer, easier and a more rational procedure. Any enlargement of the uterus vastly increases the difficulties of the operation and offers another objection to vaginal hysterectomy.

IMPORTANCE OF EARLY RECOGNITION OF CANCER OF THE UTERUS.*

WM. H. HUMISTON, M.D.

Associate Professor Gynecology in the Med. Dept. of Western Reserve University; Gynecologist-in-Chief of St. Vincent's Charity Hospital; Consulting Gynecologist to the City Hospital, etc.

CLEVELAND, OHIO.

The importance of early diagnosis and prompt surgical interference in carcinomatous disease of the uterus has been so repeatedly and emphatically emphasized by all writers, and the various methods and innumerable forms of technique discussed that I feel much like offering some apology for again asking your attention to the subject of carcinoma of the uterus.

However, it is not so much its early diagnosis or the manifold methods of technique in vogue of which I wish to speak a few words, but the manner of its recurrence as we have but recently learned from laboratory research and clinical experience.

It is well established that practically the only form of cancer which attacks the body of the uterus is the adenocarcinomatous variety. This is also of the most frequent occurrence in the cervix. The epitheliomata are usually confined to the vaginal portion of the cervix, and extend to the vaginal walls, and even when large areas become involved are less liable to give early metastasis.

The epitheliomatous nodular masses occurring in the cervix—resembling in their earlier state the pathologic characteristics of the scirrhus variety common in the breast—are slow to give rise to metastasis, and offer the best chance against a recurrence after a complete extirpation of the organ.

There are three modes of recurrence which are recognized by most authorities: 1, by metastasis—by far the most common—a lymphatic involvement; 2, by incomplete removal of carcinomatous areas; 3, by infection or direct implantation of carcinomatous cells in previously healthy tissue at the time of operation. Practically I regard this latter of little account, although I take every precaution to avoid such an infection.

I believe it is of vital importance to know the original seat of the malignant growth, and particularly should its pathologic variety be determined by a careful microscopic examination before operation. For, if it is found to have arisen in the cervix, and is of the adenocarcinomatous variety, we have to recall the fact that a recurrence is apt to be metastatic; if of the portio vaginalis, a recurrence is most apt to be in the seat of the resulting scar by incomplete removal of infected areas in the vaginal walls.

A few words as to what has been learned in regard to recurrence. I need say nothing further about incomplete extirpation or infection, as these subjects are easily understood and readily appreciated.

Perhaps some of you may recall cases of puerperal infection through an injury to the cervix in which a rapid spread of infection has quickly given rise to a general septicemia, and in which cases the condition of the uterus and its adnexa seemed to be but slightly implicated.

An instance of this occurred at the City Hospital last autumn. A young woman was admitted having a temperature of 106 F.; and a pulse-rate of 130. She had some tenderness and enlargement of both the liver and spleen, and was treated for ten days as a typhoid with no good results from the ordinary tub baths. No history referable to a diseased uterus could be had. To settle this point, however, I was asked to see the case. I found a swollen cervix, an enlarged uterus with its normal mobility somewhat impaired, with induration in both broad ligaments. Cultures were made from the cervical canal and a streptococcus was found to be the exciting cause. An injury to the cervix by an unclean instrument, direct infection of the glands in the parametrium, and the general lymphatic infection were the successive steps. With continued rest in bed the patient's local condition entirely subsided, and excepting the result of a septic myocarditis she had quite recovered. This is not an uncommon result where abscesses do not form in the affected glands. Again the tubes or ovaries become involved by direct lymphatic infection and the body of the uterus remains free of the disease.

To understand the course of such infection a knowledge of the lymphatic system must be gained. The same comprehension of this particular anatomic feature must be had to appreciate the difficulties to be overcome by the surgeon who operates for carcinoma of the uterus.

I must frankly admit that we clinicians are indebted to the men who devote their time to laboratory work for the advances which we are making to-day in this field, and our ready acceptance of their results show our appreciation of the worth of such research work.

I quote W. W. Russell of Johns Hopkins University: "The direction of the lymph vessels supplying the different portions of the uterus and vagina, and the position of their glands, can be separated into three distinct groups. The first group corresponds to the uterine vessel and its terminal branches, and supplies the upper one-third of vagina and cervix. The first glands connected with this group are found in the parametrium at the broad-ligament bases, a short distance from the cervix. They are not constant, and when present are often so small that they are frequently not discovered during operation. The most important glands belonging to this group are those lying about the iliac vessels at their dividing point.

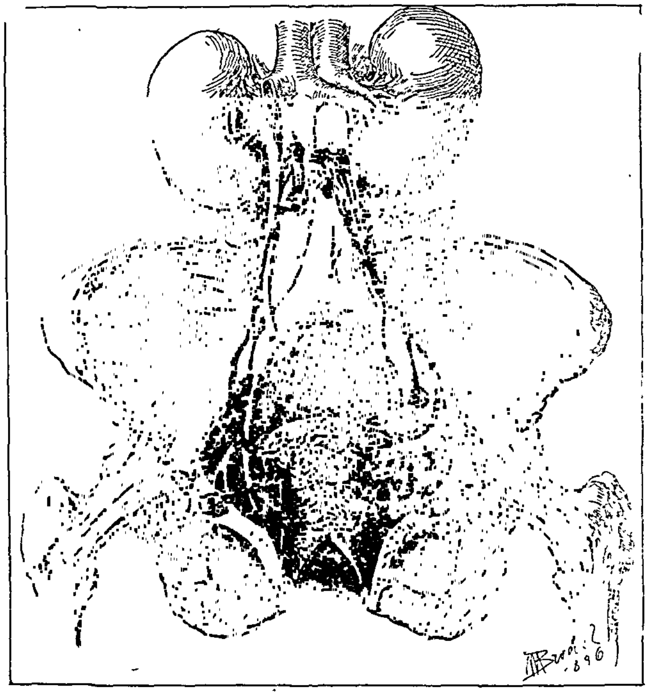
"The second group is comprised of the lymphatic vessels supplying the greater portion of the uterine body. They converge from the fundus and body, and gradually unite into two large vessels which pass outward along the upper surface of the broad ligament in close relation to the ovarian arteries. From their course it is seen that they pass between the tube and ovary. The first glands met with in this group are those in the lumbar region situated at about the level of the lower border of the kidney, directly in front of the aortic vessels and partly surrounding them.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

"The third group consists of vessels originating in the uterine cornu and passing out into the round ligament to the inguinal glands. One large vessel on either side of the uterus gives free anastomosis between body and cervix.

"The practical import of this division is as follows: There exist three avenues of escape for malignant growths of the uterus. The first group of these vessels must always be considered in disease of the cervical canal and vaginal portion of cervix, and the second and third groups in disease of the fundus, and it is through these, and these only, according to their separate divisions, that metastases are of operative significance. When the disease has passed beyond the limits of either group, rendering possible the invasion of the lymph vessels of the body by growths originating in the cervix, **or vice versa, all chance of complete removal is gone.**"



Russell.—Lymphatics of uterus and upper third of vagina.

My results in the last three years show so far one recurrence of the adenocarcinoma of the body of the uterus. In this case I performed a vaginal hysterectomy by clamps and inadvertently left a loop of the right tube in the grasp of the clamp. Microscopic examination of the portion of the tube removed showed an involvement at its extreme proximal, but free at its distal, extremity, where it had been clamped. However, in six months there was an involvement of the whole cecum, and I am forced to believe it was due to an *incomplete* removal.

I operated in 1899 upon three particularly interesting and instructive cases of adenocarcinoma of the cervix. Two are dead, one still lives but there is already evidence of some involvement in the glands at the base of the right broad ligament.

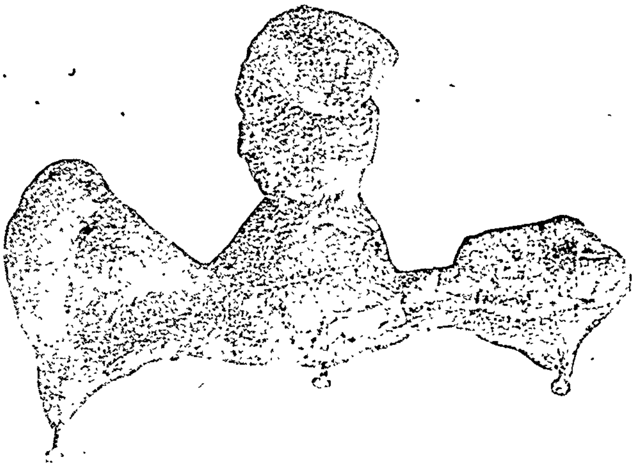
In no case of complete hysterectomy, either by vaginal or vagino-abdominal methods, have I ever had in any of the varieties of carcinoma a recurrence in the scar in the vaginal vaults.

CASE 1.—A. B., age 38 years, had two children, one miscarriage eight years ago. Family history negative as to cancer. Early menstrual history also was negative. Three months prior to her first examination she had prolonged and increased *quantity of menstrual flow. Thereafter she noticed* an occasional bloody discharge accompanied by a very bad odor. She consulted her family physician, Dr. Diemert, who recognizing the condition immediately referred her to me. On examination I found the cervix to be completely involved, the body enlarged, but the vaginal walls and vaults free from encroachment. A microscopic examination showed the condition to be an adenocarcinoma.

Her general condition was very bad. She was addicted to the daily use of large quantities of morphin. She had a weakened heart muscle, and a chronic parenchymatous nephritis. I advised early operation, and decided that her best chances for immediate results were by the more rapid method of vaginal hysterectomy. I operated Jan. 29, 1899, using the clamps.

Her convalescence was as rapid as could have been expected. She left the hospital in five weeks. In July, I was called to see her again. I found the scar in the vagina free, but the glands along both pelvic walls and generally throughout the belly were involved. She lived until September, 1899.

CASE 2.—L. A., aged 37, had seven children, two miscarriages. Early menstrual period was negative. I had operated on a maiden sister one year previous for a sarcomatous myoma; no other malignant disease in her family history could be ascertained. She had been flowing profusely for a number of months at each menstrual epoch. She had called Dr. Borts to stop the hemorrhage two months before she came into the hospital. At this time she refused any local interference. At the next period the doctor found her in collapse, hurriedly packed the vagina and applied the usual remedies for restoring her. The next day he insisted on making an examination, and found a complete disintegration of the cervix. I was called and advised removal to hospital. I first removed the disease by curette, afterward applying a cautery. In May, 1899, two weeks after, I performed a combined vaginal and abdominal hysterectomy, making a most careful dissection of the glands along the iliac vessels, and removing every particle of fatty *substance at the base of the broad ligaments.*



Nullipara, aged 30 years. Adenocarcinoma of cervix, double pyosalpinx. Vagino-abdominal Hysterectomy.

This patient died in four months with general involvement of the lymphatic system, though the pelvis was entirely free from any recurrence.

CASE 3.—E. H., married, aged 28, was nulliparous. She had never been robust. There were hereditary tendencies to tuberculosis from both paternal and maternal sides of the family. A brother has some malignant tumor of jaw. Her early menstrual period was negative. She was admitted to Charity Hospital on November 15. 1899. Four months
mittance she had first noticed a watery
with yellow. Since that time she had a
charge. She had been suffering from

the lower abdomen and both groins. Upon examination a diagnosis of double pyosalpinx was readily made, but the condition of the cervix aroused a suspicion of malignancy. A portion was removed and submitted to microscopic examination, and an adenocarcinoma was found.

On December, 1899, she submitted to an operation for complete extirpation. I could find no glands at the base of the broad ligaments, and those along the iliac vessels were not affected.

In January she returned for an examination, and I found a small gland at the base of the left ligament, and two in the right side, together about as large as an almond. They were tender on pressure. This tenderness has decreased with local applications of ichthyol, and while there has been no appreciable increase in the size of the glands during the past four weeks, I find no diminution.

It has been my experience that the most common form of cancer of the cervix, the adenocarcinoma, is by far the most to be dreaded.

1. Because of its natural growth in expanding laterally into the parametrium. (See Figure.)
2. Because the lymphatic vessels and glands in the parametrium are so small that they may easily be overlooked, yet may be infected.
3. Because of the indirect connection to the chain of glands over the iliac vessels.

The practical import of this paper can be summarized thus:

1. Early differentiation of malignant growths of the cervix.
2. Careful consideration of the importance of the lymphatic vessels and glands in their capacity of drains of the different portions of the uterus.
3. That abdominal section with complete removal of these special groups of lymphatics alone offers in suitable cases the chance against a recurrence of carcinoma, particularly when the cervix is affected.

OPERATIVE TREATMENT OF CANCER OF THE UTERUS.*

WIILIAM R. PRYOR, M.D.
NEW YORK CITY.

A paper on this subject can not contain anything startlingly new until something additional regarding the nature of cancer has been discovered. Nothwithstanding that this is so, we have gained sufficient experience in its treatment to be able to make a just analysis of the various methods employed, and in this way review as it were our work in combating a disease which in America must destroy 30,000 women annually. We may also find some light in a careful study of the natural history of the disease when left unchecked, and in an analysis of the cases in which recurrence has taken place after operation. Although this paper is not to deal with the etiology of cancer, I can not refrain from calling attention to the burden of proof pointing to the theory that cancer of the uterus is caused by a parasite. And although we can not accept without further convincing evidence the statements of Max Schüller regarding its nature, yet whatever method of treatment we apply to cancer it must not violate the principles which should govern us if the disease were proved to be due to a germ. In view of the results obtained by experimental work, any method of treatment which proceeds in disregard of this work can not be classed as proper. It is eminently fitting to analyze several of the chief methods of treatment and in doing so I will first take up the operation of *vaginal hysterectomy*. This is as firmly established in the minds of the profession as the proper procedure as is any in surgery; but at the risk of meeting your disapprobation and that of many who read this paper I shall lay bare the facts.

Notwithstanding that Olshausen has succeeded in doing a hundred operations without a death due to the procedure, a success which I believe has been imitated by Leopold, we must ascribe to vaginal hysterectomy for cancer of the uterus, taking into consideration the statistics of all operators, an average mortality of 10 per cent. This mortality is trivial considering the gravity of the disease for which the operation is performed, and the difficulties inherent in the procedure. The operation is therefore to be considered in the light of its results rather than in its dangers; for the ingenuity of the surgeon has not devised a procedure more beautiful, requiring greater dexterity in its proper performance than this operation of vaginal hysterectomy for cancer: "the German operation," as Olshausen calls it. Operators will of course be loath to relinquish a piece of work which is so apparently surgical in its principles and stands on such a distinctly anatomical basis as this, for some new method of treatment.

Let us consider the results of vaginal hysterectomy for cancer. Statistics can be twisted both in their formation and in their interpretation so as to strengthen almost any argument, the point of view of the observer largely governing the result. But in the matter of cancer statistics a most commendable spirit has governed the profession, and each reporter seems to strive to tell the exact truth only. Personally, I do not believe that a woman who has suffered from carcinoma of the uterus and has been operated on should be considered out of danger of recurrence until six years have passed. Let us take the experience of Jessett. This surgeon found 58 per cent. of his vaginal hysterectomies for cancer of the cervix, free after one year, and 40 per cent. free after six years; of his operations for cancer of the body of the uterus, 83 per cent. after one year, and 60 per cent. after six years.

Mortality.—In estimating this I take at random three groups of operators in Germany, France, and England and America, a total of 1087 cases with 10 per cent. mortality. John Byrne found in 1273 cases a mortality of 14 per cent. The latest figures are by Picque and Mauclaire, up to 1889, 2376 cases with 9 per cent. mortality.

Leopold, Kaltenbach, Dimitri de Ott, Landau, Olshausen and Jacobs out of 438 cases had 16 deaths, or 3.65 per cent. Terrier, Doyen, Segond, Quenu, Richelot and Bouilly out of 286 cases had 47 deaths, or 16.4 per cent. Jessett, Lewers, Lanphear, Purcell and Russell out of 363 cases had 43 deaths, or 11.8 per cent.

As regards remote results of vaginal hysterectomy for cancer of the cervix, Jessett after 6 years had 40 per cent free; Jarvin after 4½ years, 37½ per cent.; Longuet after 3 years, 14 per cent. (6 operators). Lanphear after 3 years found 31 per cent. free; Russell after 3 years, 41.7 per cent.; Thorn after 6 years, 27.5 per cent.; Berry after 2 years, 12 per cent (5 operators). Jacobs found that 50 per cent. of his cases relapsed in the first year. The average after 3.9 years was 29.1 per cent.; average mortality was 11.5 per cent.

In vaginal hysterectomy for cancer of the body of the uterus, Kukenberg after 5 years found 66.7 per cent.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

free; Lewers after 2 years, 83.3 per cent.; Jessett after 6 years, 60 per cent. The difference between the results of vaginal hysterectomy when done for cervical cancer and when performed for corporeal cancer, is striking. The mortality of the two operations is about the same.

High Amputation of the Cervix.—Thomas More Madden reports 31 cases of amputation of the cervix with recurrence in 1 case in four years. Five recurred within a year, and 2 in two years, 1 in three years, 1 in four years, and in 10 cases or 30 per cent. there was no recurrence within four years. He has 5 cases free after two years, and 6 cases free after one year. The total shows 71 per cent. free after one year and 51.6 per cent. free after two years.

In analyzing the operation of high amputation for carcinoma of the cervix, Baker, of Boston, reports 62.5 per cent. of cases free after two years, and without the loss of a patient directly from the operation. A personal communication from Dr. Baker a few days ago stated that he was more convinced than ever of the efficacy of high amputation.

John Byrne traced 40 cases operated upon by his method and found an average exemption of nine years, this operation being performed in early cases. He traced 50 cases which were advanced when operated on and found 10 exempt over two years, 11 over three years, 6 over four years, 8 over five years, 6 over seven, 2 over eleven, 1 over thirteen and 1 over seventeen. After two years there were 90 per cent. free. Lewers found 33 per cent. of his cases well after two years.

As far as the *sacral method* of operating is concerned Westermark collected 104 cases with a mortality of 24 per cent. In view of what can be accomplished by the preliminary hemostasis through the abdomen and of the combined abdominoperineal method of extirpating the uterus and rectum through the vagina, I can not see what advantage the sacral method can have in advanced cases. Jacobs, in comparing abdominal hysterectomy in 15 favorable cases, finds no relapses from several weeks to twelve months, and contrasts this picture with the series of 81 cases of vaginal hysterectomy showing relapses in 41 cases within a year. The importance of removing the vagina together with the uterus as well as the value of heat in closing the mouths of the absorbents as the operation progresses is well shown by Mackenrodt, who contrasts 81 per cent. of the recoveries at the end of one year by his method with the old method, finding that by the latter at least one-third of the cases have relapsed within one year. His very able paper should be read by all interested in cancer.

Halsted found in cancer of the breast that after a more radical operation 52 per cent. of the cases lived more than three years; the operation as previously performed for cancer of the breast gave but 20 per cent. free cases after three years. I am again forced to differ from my friend, Dr. Kelly, as to the analogy between cancer of the breast and uterine cancer, and I insist that the same requisites to success must be observed in operating for cancer of the uterus as in other parts of the body.

Roger Williams, in a discussion on early operation and late, quotes Leopold's statistics that in the early cases—where it is necessary to confirm the diagnosis by the microscope—recurrences take place in 23.7 per cent. only; whereas in advanced cases recurrences take place in 66 per cent.

It is not necessary to multiply statistics further, for in reality a careful analysis of a proper report by one accurate observer will suffice. Some operators, like Bouilly, Polk and many others, believe that all cases of clinical cancer relapse after vaginal hysterectomy, and I do too. All operators agree that the widest possible dissection should be made, and the broadest removal of tissue. If vaginal hysterectomy for cancer carries with it a general mortality of 10 per cent., and if after five years no more than 20 per cent. of the cases are free from relapse, I can not see how the operation can be advocated against the claims of high amputation, which has practicaly no mortality inherent in it and which gives far better results. But the operators will not rest content with the results obtained by high amputation even though they are better than those seen to follow vaginal hysterectomy; for in a sort of fierce determination to combat this curse of our civilization they seek not only preventive measures, but an operation which will grant a greater immunity against return of this disease. If then we can show that the mortality inherent in a certain piece of work is no greater than that which follows vaginal hysterectomy, and if we can demonstrate that by means of this operation the broadest possible dissection and removal of tissue are possible, and that there is the least possible chance of soiling of the field of operation and dissemination of the cancer cells during its performance, we are in a position to command the attention of the profession for such an operation. Furthermore, we are bound to be guided by the analogy of operations performed for the same disease in other parts of the body if the same principles are involved. It will not do to apply laparotomy in only the advanced cases, as some suggest, reserving for vaginal hysterectomy the easy and early cases, and then contrast the statistics of the two operations. If an operation is indicated for the grave types of cancer it is still more forcibly indicated in the early cases, for the indication of operation in cancer is not so much the local state as it is the tendency to recurrence.

A consideration of these statistics forces us to the conclusion that vaginal hysterectomy for cancer of the body of the uterus gives far better results, both immediate and remote, than are seen to follow the same operation for cancer of the cervix. Some operators have attempted to modify these figures by dividing their cases into late cases and early cases. As the cancer comes to us, if we can make a diagnosis from clinical symptoms, the case is to be classed as a late case; whereas, if cancer is suspected and the diagnosis is confirmed by the microscope, the case is to be classed as an early case. The differences in the recurrences of the two classes of cases are stated by Roger Williams as 23.7 per cent. in the early cases, and 66 per cent. in the late cases; and, inasmuch, as of all cases of cancer of the uterus which come to us but 10 per cent. can be operated on by the vaginal route, we are forced to the conclusion that vaginal hysterectomy is not an admissible operation for cancer of the cervix except in a very small and selected percentage of cases, and the propriety of performing it in these cases may be disputed; for it is possible that other operative procedures less severe would give better results in the same class of cases. It may be interesting to determine why better figures are obtained when the operation of vaginal hysterectomy is performed for cancer of the body of the uterus. Two factors, I believe, conduce to this: first, in cases of cancer of the body of the uterus we can ither the infected area than in the operati cervix, and during the operation s soiling the field of operation by forcing them into the absorbents. We may with propriety compare the results obtained from two less severe operative procedures with those which follow vaginal hysterectomy.

Byrne's method of removing cancer of the cervix has unquestionably given better results than vaginal hysterectomy, and the same may be said of the method which Sims advocated and which is adopted by Herbert Snow, Lewers, More Madden, Knowsley Thornton, and Baker, of Boston. So then, vaginal hysterectomy for cancer of the cervix, after years of trial and though as perfect an operation as it has been made, must be discarded because it has not stood the test. It is not so with vaginal hysterectomy for cancer of the body of the uterus, for this grants an immunity almost as great as could be expected. I will not speak of palliative methods of treatment, methods of injecting alcohol, methylene blue, and other remedies, nor of inoculation experiments. Cancer, like other chronic diseases, has a list of these nostrums too long to cite.

In searching for an operation or method of treatment which will place surgeons in a better position before the profession at large and grant our patients greater immunity against recurrence, we should consider the methods by which cancer extends, and also the requirements of a successful operation.

Roger Williams found in autopsies on cases which had died with cancer, that the vagina was involved in 92 per cent. of the cases, and that the lymphatic glands were involved in 71 per cent. Hofmeir found the parametric tissue involved in 96 per cent., Peiser in 50 per cent.; Kiwisch the Fallopian tubes involved in 24 per cent. These investigations show, then, that unchecked cancer has a tendency to spread to the parametric tissue and the vagina and to the lymphatic glands, and in frequency in the order in which I give them. A significant fact is that metastatic growths outside of the pelvis are rarely found, and that the cancerous involvement has a tendency to be limited to the pelvis; and when recurrence takes place it is usually in the pelvis, and most commonly in the vagina or parametric tissue. The anatomic requirements of a successful operation for cancer of the uterus will necessitate the removal of a portion, at least, of the vagina, all the parametric tissues and all the lymphatic glands in order to prevent recurrence, and the surgical requirements are that this removal be made in such a way as to be practically bloodless and to prevent introduction of even microscopic portions of the cancerous tissue into the absorbents. These requirements are fairly well met when the vaginal operation is performed for cancer of the body of the uterus, but are violated in every essential when the operation is done for cancer of the cervix. Although some operators cleanse the field as thoroughly as possible before proceeding to the extirpation, and others use the actual cautery for the purpose of closing the mouths of the absorbents, these procedures are rendered ineffective owing to the mechanical bruising and pressure to which the cancer is subjected during the operation of removal through the vagina. Vaginal hysterectomy not only ignores all that has been done in the bacteriology of cancer, as soiling of the field of operation is inevitable, but it also mechanically and of necessity projects the cancer cells beyond the field of operation. If this is true of the German operation of vaginal hysterectomy for cancer—the operation which is performed in America—the criticism applies still more forcibly to the operation proposed and practiced by Duret in 1895, recently revived by Kelly, viz., by morcellating the cancerous uterus. And, whereas, I have been able in a few cases of vaginal hysterectomy to make so careful and minute a dissection of the tissues as to enable me to secure the uterine arteries outside the ureters, and in this way make a broader removal of tissue, I am convinced that I violated the two essentials to a successful removal of cancer of the cervix, in that I could not avoid soiling the field of operation by the cancer cells, nor could I avoid pressing the cancer cells into the absorbents.

Let us consider the question of the site of recurrence. Hofmeier found that the parametric tissues were first involved in 95 per cent. of recurrences observed by him, and this is corroborated by Winter. Personally, I believe that the parametric tissue is involved before we see a manifestation of the disease in the vaginal scar. Now, considering the paths by which the disease normally extends, the position in which it recurs and the requisites of a successful surgical operation, we must abandon vaginal hysterectomy for cancer of the cervix and must class it merely as a palliative operation, which carries with it a mortality and gives results not as good as high amputation. Whether we proceed on the theory that recurrence is due to the fact that some of the primary cancerous tissue in the cervix is left, or that cancerous foci away from the cervix in the vagina or in the parametric tissue are left behind, or again whether we accept Roger Williams' opinion that recurrence after two years' interval is not recurrence but a fresh outbreak of cancer in tissue subject to disease, and in a patient specially prone to it, we must decide that vaginal hysterectomy, beautiful operation as it is and challenging our admiration, is a failure when applied to cancer of the cervix.

I have shown that vaginal hysterectomy in no wise meets the requirements of a proper operation for cancer of the cervix, and that it does not grant a sufficient immunity against recurrence. An operation to be called successful must remove the lymphatic glands, must remove the parametric tissue, the ovaries, tubes, uterus and at least the upper third of the vagina. In its technique it must embrace an almost perfect sterilization of the wound and a closure of the absorbents. This is met by a preliminary burning of the cancer field and an absolute hemostasis before beginning removal of organs involved. High amputation as performed by Byrne, with the cautery, by knife and scissors, as done by Baker, Knowsley Thornton, More Madden and others, closes the absorbents and make a local removal only. This operation therefore meets some of the requirements of a successful operation, whereas, vaginal hysterectomy meets none, and as a consequence we find that the operation of high amputation gives better results than vaginal hysterectomy.

I am not satisfied that these results are sufficiently good, and have been for some years trying to improve them. Polk, Rumpf, Ries, Clark, Werder and Mackenrodt have attempted the same thing. The dissatisfaction with the vaginal operation is becoming very common, and before we adopt any operation we should be very careful to state the grounds on which it should proceed; these should be based upon the requisites I have given. It is not necessary for me to describe the operation of ligation of the internal iliac arteries nor the steps taken to remove cancerous tisue after this operation. The technique of the operation I have several times given, but its remote results I am not prepared to publish, inasmuch as not sufficient time has passed. Suffice it to say that I have ligated the internal iliac arteries nine times for advanced cancer, and that one case died, not from hemorrhage or from sepsis but from acute nephritis, the autopsy finding small red kidneys, which before operation did not reveal themselves. I maintain that by no operative procedure can a bloodless field be created except by a preliminary ligation of both ovarian and internal iliac arteries. When this step is preceded by the thorough cleansing and charring of the cancer field I believe we prevent not only the introduction of *cancer cells and germs into the absorbents but we* insure against local soiling by these. I know of no other way by which we can remove all the glands from the pelvic brim to the obturator foramina, the broad ligaments, the parametric tissue on each side of the uterus, beneath the ureters and to the sides of the rectum and vagina, together with the vagina. Objection may be made to this operation that it is unnecessarily severe and that it may require more skill in its performance than is possessed by the average operator. Regarding skill and acquaintance with the technique, these can be secured by repeated operations on the injected cadaver. The severity of the operation is indicated by the mortality accompanying it, and I have lost but one patient in nine operations, all for advanced cancer; in two of them I removed the rectum as well. Besides, I may remind you that we are dealing with cancer, and if an operation were presented to me for this disease which carried with it a mortality of 20 per cent. and yet granted an immunity after five years of 60 per cent., I would accept it in view of the utter failure of vaginal hysterectomy. In making this attack upon this established operation I feel that I am not alone, for Roger Williams in England is leading the same fight. On the continent, Jacobs, Bouilly, Rosario Vitanza, Rumpf, Veit, Freund, Reynier, Ricard, Ségond, all express the uselessness of vaginal hysterectomy and the necessity of adopting some other method of operating. In this country, Ries suggested the operation first performed by Rumpf and elaborated by Clark. Penrose elects the abdominal route, Russell the same. Werder, Irish, Polk, and perhaps many others whose work I do not know so well, are with me in this matter of the inutility of vaginal hysterectomy in cancer of the cervix and *for the necessity for a radical abdominal operation.* Lanphear, Howard Kelly, Janvrin, Coe, Goffe, Wylie, and I believe the great mass of operators in America, are still performing vaginal hysterectomy for cancer of the cervix.

Let us glance at the mortality incident to the abdominal operation. In *Revue de Mal.,* for March 20, 1900, it is stated that abdominal hysterectomy for cancer has a mortality of 23 per cent. This I deny is the result in America. Ries notes 3 deaths in 15 operations—ligation of uterine artery, removal of glands, etc., by laparotomy, the Rumpf-Ries-Clark operation—20 per cent. Irish notes 25 operations, 3 deaths—progressive ligation by laparotomy—12 per cent. Pryor gives 9 operations, 1 death—ligation of internal iliacs, removal of all glands and portion of vagina, by laparotomy—11 per cent. Penrose has 7 operations, and no death—progressive ligation by laparotomy. Jacobs reports 23 cases, 1 death—progressive ligation and glands removed by laparotomy—4 per cent. Russell has 5 cases, and no death—3 by Rumpf-Ries-Clark method, 2 by Werder's method. Polk reports internal iliacs tied 4 times, anterior branch of internal iliacs tied 10 times, 14 cases, 3 deaths, 21.4 per cent. Total is 98 cases, with a mortality of 11.2 per cent.

Most of the operations done by Rumpf, Polk, Ries, Clark, Pryor, Werder, Russell, and those who agree with us in our views, were of a more radical type than those of Irish, Penrose and Jacobs, and in women who would have been refused by most of those who operate through the vagina, and yet the general mortality is 11 per cent. only. None of us has yet had great experience, and when we get it and properly select our cases, the mortality will necessarily be much lower. The gratifying feature about this new abdominal operation is that it gives *no greater mortality than follows* vaginal hysterectomy.

The object of my paper is to show as forcibly as I can the uselessness of vaginal hysterectomy, and to present to the profession the urgent necessity of reviewing our work and adopting that operation which will enable us to make the broadest dissection, to remove the most tissue, to remove all tissue in which recurrence is liable to take place, in a bloodless field and in such a way as will insure local cleanliness and prevent introduction of the germs into the absorbents during the operation.

DISCUSSION ON PAPERS OF DRS. HALL, DEAVER, HUMISTON AND PRYOR.

Dr. H. J. Boldt, New York City—I think this subject is one of the most important brought before the Section at this meeting. I should like to call attention to the location of the neoplasm as classified by Dr. McMurtry. He divides into cancer of the cervix and cancer of the body. As a whole, this is correct in one respect, but from a clinical standpoint it is not the case. We must determine which operation we are going to perform, a vaginal or an abdominal hysterectomy. Cancer of the supravaginal portion of the cervix is more difficult to recognize, and those cases go the longest time before they are referred to a gynecologist for diagnosis and treatment. That, therefore, is an important consideration.

The ordinary form of cancer of the vaginal portion, unless it be the so-called erosion cancer, it not difficult to recognize; I refer to epithelioma or cauliflower growths, and they usually come to the physician much earlier than the other cases.

As to prophylaxis, it must be borne in mind that there is no form of disease which leads to malignant degeneration so readily as long-continued inflammatory conditions of the mucosa. Therefore, cervical fissures accompanied by inflammation of the mucosa are very prone to produce cancer.

As to the papers of Drs. Hall and Deaver, I will ask them what is the outcome of their cases three years after the operation. The technique Dr. Hall has described is a most beautiful one, but how many cases remain free from the disease after a few years of time? We must always bear in mind that the age of the patient is a most important factor in connection with the location and the extent of the disease. In regard to the ligature and clamp, the former is the neater operation, and I should always advise and use it, if consistent in a respective case. But to say that one can take off as much of the broad ligament with ligatures as with clamps is, in my opinion, erroneous. There is no danger of secondary hemorrhage if proper clamps are used. Cases which are advanced with the broad ligaments infiltrated are not going to live very long. In my experience they usually die within a year or so. We should therefore limit ourselves to the early cases. As Dr. McMurtry said, the chief factor is an early diagnosis. It is not sufficient to go into the uterus with a small curette and scrape a little endrometrium away, but every part must be curetted. If a small piece as large as a pin-head of malignant structure is secured it is sufficient to base a diagnosis on and to do a radical operation.

In discussing the malignant diseases of the uterus, the chief question is: What are the ultimate results? As far as the abdominal operation is concerned, my experience is too limited. Dr. Pryor has truly said that our experience in toto is too limited. Time will show whether the abdominal operation is superior in its ultimate results; as yet we can not speak with positiveness on this point.

Dr. J. M. Baldy, Philadelphia—It is entirely the practical aspect of gynecology that appeals to me. As to the technique when a major operation is to be done, I can fully agree with Dr. Pryor and Dr. Deaver. I know of nothing so irrational as the vaginal operation. The question is: How many patients can we get well by an operation? How can we best give health or relief? The gentlemen who are doing major operations tell us that they have from 30 to 60 per cent. of cures at the end of a certain period. They probably had excluded a hundred cases on which they would not operate, picking a half-dozen for operation. It is not fair to consider the picked cases. The question is: What relief have these gentlemen been able to give in all the cases of cancer which have come into their hands. We can not accept off-hand what figures say, because we know they can not be relied on. These gentlemen, when they include all their cases, cure one or two out of 500; it is the best showing they can make. If we wish to consider cancer practically, what will give the patient the most relief in all cases—not a few picked ones? Is it to do the major operation and kill the majority of them, or do something which will give them just as much relief as a major operation and which is accompanied by no danger? Is there anything that will do this? I am sure that there is. By referring to the medical and surgical literature of the world as it stands today, the cures are few and far between by the major operations.

We must divide cancer into two kinds in spite of the estimation by Dr. Boldt: cervical and fundus cancer. I suppose I have seen three or four hundred cancers in my life, and I have done from 50 to 150 major operations, and I do not know today of a single living case with cancer of the cervix in which I was able to make a diagnosis without the microscope. There are some I know nothing of, but judging from the others, I, in all fairness, consider that they are dead.

The fundal cancer, on the other hand, are all well, with the exception of 4 or 5 who died at the time of operation. I can put my hands on at least 13 or 14 of these women to-day who are well and healthy. What can we do to give these patients relief? Curette, scissors, knife, amputation, call it anything you wish. When you get it all away, burn, and burn as far as you can, and as thoroughly as you can. Those cases live as long as major operations and have often absolute relief. Dozens of them gain 40 or 50 pounds inside of three or four months. They have red cheeks, look well and feel well, and they usually insist that I must have made a mistake in the diagnosis of cancer. Major operations can do no more as they stand to-day. Any practitioner can carry out the one treatment—only specialists can do the major operation with safety.

Dr. G. Betton Massey, Philadelphia—Much of the lack of success in the treatment of cancer by the knife is due to delay. Such results are not infrequently due to the family physician's want of faith in this remedy, as instanced in the advice given by a physician to a patient, subsequently under my care: "Do not touch a cancer until you have to." The limitations of surgical relief are, however, very great, and I wish to call your attention to a method of treatment of cancer of the cervix, the kind of cases that have been spoken of by the last essayist and by Dr. Baldy as being least amenable to the ordinary operation. This method is surgical in spite of the fact that I bring it forward, although it is not surgical in that sense of surgery as interpreted at the present time, and which is limited entirely to the knife. This is the method of electrical destruction by the production of electrolytic salts of mercury in situ, in such a manner as to destroy the cancer as thoroughly as the knife will. This is done in the time of an ordinary operation, in from fifteen minutes to an hour and a quarter. It requires a very powerful electric current, and that is its main limitation. You must have good batteries and good apparatus. In addition to destroying the apparent limits of a cancer, it goes further by the diffusion of the oxychlorid of mercury or of zinc. Besides destroying the growth itself as thoroughly as the knife can, it produces a zone of infiltration which may be called the zone of sterilization, extending from one-half to one inch in all directions beyond the limit of the cancer. That is the distinguishing and probably the most valuable feature of this method. The method is faultless, and can easily be carried out with the proper instruments. It is rapid and sure, and is inferior to the knife operation only in that union by first intention is impossible. The dead material comes away in the ordinary manner and the cavity left heals by granulation. I have used this method on four cases of inoperable cancer of the cervix, of which two are living, one six years after the operation and the other six months. The two cases that are not living were benefited temporarily by what I call mild applications. An application was made daily for several months, controlling hemorrhage and the odor. You must remember that this is a powerful antiseptic, the oxychlorid remaining within the tissues for some time. Both of the unsuccessful cases had been operated on previously with the knife, nothing other than palliation being produced. In one of the cured cases a cure was established by the mild method, but I used 100 milliamperes for a quarter of an hour daily for six weeks, and then at longer intervals for the balance of a year. This patient is now perfectly well.

Dr. J. Henry Carstens, Detroit—Gentlemen, let us be honest. Let every one of you bring to your mind all the cases of cancer of the breast, no matter when operated on, where the axillary glands and the glands beneath the clavicle were removed—the most perfect operation. How many of these cases can you think of who are living three years after the operation without a recurrence, and how many have died? My experience is that they all recurred, and with very few exceptions they nearly all died. If you can not remove all the glands in a cancer of the breast, how in the name of common sense can you remove all the glands in the abdomen—in soft tissues where we must work around the aorta and where the operation requires a great deal of time? You can not take out every gland, you are bound to leave some of the gland and some of the lymph channel, no matter how careful you are. I will predict that the men who advocate abdominal hysterectomy will have just as many recurrences in five years as the men who do vaginal hysterectomy. Vaginal hysterectomy with me has always given poor results and I have limited my circle of operation more and more as my experience has increased. Many cases which I formerly operated on I now leave alone, because I can give my patient longer life and better well-being by palliative measures. I do not wish to say that I do not believe in vaginal hysterectomy. I can show you cases from 5 to 8 years after operation without a single recurrence, but you must get them early.

As far as electrolysis is concerned, I do not know that we are to laugh at it, but if cancer is due to the blastomyces or any other germ, and if electricity will kill it, if Dr. Massey will show a method of killing the germs in situ we will be under everlasting gratitude to him.

We must make our diagnosis early, and we must make our prognosis in all cases, even early ones, very bad indeed, as even those recur. We must use the curette and the microscope more than we do at present in order to detect cancer in the very earliest stage.

Dr. Joseph Price, Philadelphia—We are speaking to a large gathering of general practitioners and a few gynecological specialists, and a good many general surgeons. The point made by Dr. Baldy in regard to the malignancy of uterine cancers is the experience of a good many specialists. Sarcomas occur in the spinster in the upper part of the fundus, and the results by extirpation are cures. In child-bearing women the cancer commonly occurs in the cervix, rarely in the fundus. Malignancy is malignancy the world over, and always recurs except where you make the error of extirpations for cervical erosion or a crop of Nabothian cysts. In the neglected and desperate cases the curette and cautery does just what Marion Sims said many years ago in Boston. He advocated the free use of the curette and cautery before Dr. Holmes' class. I am speaking about the hopeless cases, those contaminating the atmosphere of the home. The family appeal to us to do something, because the home is becoming offensive to the family. What Dr. Carstens has said is correct. The free use of the curette and cautery, charring or cooking the parts, prolongs lives as long as a hysterectomy. It makes no difference if we extirpate, as they all come late, and sometimes they return. If they recur the deaths are easier, less objectionable to themselves and to their friends, whereas, after extirpations and recurrence in the bladder and bowel the deaths are horrible. I remember a physician's wife, from whom I removed the uterus, who came back and asked me to remove her bladder, as the growth had invaded it.

Dr. Humiston, a good anatomist, finds three sets of glands; Dr. Deaver, another good anatomist, finds two. They must reconcile this between them. There are, unfortunately, very few people who have had an opportunity of serving an apprenticeship in gynecology as we have, but there is only one well-organized department in gynecology in this country. It exists in a large hospital which is giving special departments an opportunity; and all you get there is object-lessons. Very few hospitals have organized departments for the specialties. Just here I want to pay my respects to the general surgeon, who is also entering this department. It seems that everything pertaining to sexuality is interesting, and it is the only excuse I have been able to think of for the general surgeon giving up his work and adopting ours. You must remember that many of us were general surgeons and made a great sacrifice when we entered our specialty. My brother and I made great sacrifices, giving up surgical work and a good obstetrical and family practice, which it took years to build up, in order to devote our time to gynecology. I regret that the good surgeons in Philadelphia neglect their general work and are adopting ours. If I were a younger man I would go back to general surgery, remove wens, treat ingrowing toe-nails and present the specimens at our county society. A few years ago I put three good surgeons to the test. I sent John Deaver an aneurysm case and two other general surgeons three cases each. A few days afterward I asked my students what they saw in the various hospitals to which these cases had been sent. At one hospital the "surgeon removed a pair of ovaries"; at another, "Dr. So and So "removed a pair of ovaries"; at the third the "surgeon removed a pair of ovaries." That is all they could tell me and all they had seen. Then I considered where I could send my cases after that. If our specialty is to be a specialty, let us begin now to teach it and practice it as such. It is the duty of all of you at the cross-roads to save the woman dying from an extrauterine pregnancy or from an appendicitis or a septic endometritis, as you have *no time* to ship them to Philadelphia. If general surgeons accept your money for four years it is their duty to educate you *to treat* those people at the cross-roads and not to meddle with the specialties. The teacher has been neglecting his duty to his profession. You all know that the general surgeons practice gynecology in jack-knife or rule-of-thumb fashion, and know as little about gynecology as a Chinaman does about teaching Sunday school. At present many general surgeons are practicing gynecology and professing to teach the great subject of general surgery. He is making precisely the same mistake as the professor of obstetrics is guilty of—professing to teach one specialty while practicing another.

Dr. A. H. Goelet, New York City—There are three points which should be emphasized, first, early diagnosis, and we can not insist too strongly on the family physician being impressed with this fact. Something over a year ago a physician in a Connecticut town sent me a patient to be operated on for cancer of the uterus. I sent the patient back to *him* with a note saying that he could cure the case himself in six months, as it was senile endometritis. I saw him later and he told me that the patient had entirely recovered under the plan of treatment I had outlined and which he carried out.

The next point is early operation. If a positive diagnosis of cancer is made, a radical operation should be done at once to remove the diseased tissue, and remove it thoroughly. As a case in point, a patient came to me about three years ago and I insisted on immediate operation. She had a cancer involving the body of the uterus. She left me in order to consult other specialists and many general surgeons in New York. They all advised the same thing. A year later her daughter came to me and asked me to operate. Their excuse for not accepting my advice in the beginning was that the family physician told her she had better wait, as it was not bad enough for an operation. I refused to operate, as I deemed it too late. She died a few months later.

The third point is that if the cancer has attacked the body of the uterus we should insist upon operation by the abdominal route, so that we can see what we are doing and so we can do more thorough work. I wish to place myself on record as favoring the abdominal route in cases where the disease has advanced beyond the cervix.

Dr. John Byrne, Brooklyn—I hesitate very much, on the present occasion, to take up your time in attempting to discuss a subject of such vital importance as the treatment of uterine cancer. Indeed, had I anything novel or of practical value to offer the few minutes allowed me by your necessary rules would hardly suffice. Besides, what I might say would, for the most part, be but a repetition of what I have been saying and advocating for the last 25 or 30 years.

Throughout the published transactions of the American Gynecological Society may be found the records and statistics of my work. These have been and are to the profession public property, and within the reach of all, and yet, though conceded to be singularly attractive, both as regards novelty of procedure and results obtained, few, if any, have followed my example or attempted to conduct electrocautery operations in a rational, not to say thorough, manner.

As Dr. Baldy has aptly said, what most concerns us and the community at large is the question: How many lives can we save by any operative measures in cancer of the uterus? How many lives can we prolong in comparative peace and comfort by operative measures? These are pertinent and practical questions, and I think I can confidently refer to my records for their elucidation. Thoroughly convinced as I am of the utter inutility, to say the least, I deny the legitimacy of hysterectomy for cancer of the cervix in any case. There is no example of malignant disease of that organ, with the exception of carcinoma of the fundus, and that ab initio, for which hysterectomy is useful or justifiable. As for primary mortality following this operation, its advocates have been in the habit, from time to time, of indulging in the wildest and most unwarranted statements and predictions—for example, that 5 per cent. would be an excessive estimate, and that by increasing familiarity with the operation and more perfect technique, primary mortality would be reduced to 2 or 3 per cent. Now, what are the facts? In 1892, as the result of an exhaustive study and careful analysis of all available data, and exclusive of probably thousands of cases which their exploiters have modestly withheld from the impress of cold, unsympathetic, and inexorable type, the actual primary mortality was found to be no less than 14 per cent. Again, seven years later (1899), a similar investigation resulted in the discovery that, instead of a reduced mortality directly attributable to the operation, the figures had crept up to over 20 per cent. Coupling these startling facts with the well-known reticence of our gynecological statisticians regarding recurrences, and about which they would seem to think "the less said the better," the conclusion arrived at ten years ago is fully sustained and emphasized, viz., that " over 90 per cent. of all the victims of cancer of the cervix uteri thus far submitted to hysterectomy would have lived longer and suffered less if they had been let alone." In brief, gentlemen, there is but one safe and successful method of treating these cases, and that is by electrocautery. Careful, slow and thorough excision of the diseased part by the heated knife, and repeated applications of the dome-shaped electrode to the remaining cavity, until the parts are dry, crisp and black, will be found an absolutely safe, and in the early stages of the disease a permanently curative, procedure. Moreover, in more advanced cases a similar course will be followed by a longer respite from relapse than from any other known method of treatment. I hope the day is not far distant when hysterectomy for cancer of the cervix will not only be abandoned as useless, but universally condemned as a criminal operation, which I believe it to be.

Dr. Phillips—I have been listening to see whether anything would be said as relating to the converse side of this picture. It has been my fortune to see, within the last six months, several cases of complete hysterectomy that I believe showed no cancer of the uterus. I believe they were simply chronic erosions. It has been my misfortune, too, to see many cases of amputation of the cervix, which I am thoroughly convinced were never cancer. Some of these diagnoses were made by the general surgeon, some by the general practitioner and a few by the gynecologist. I believe that there are many cases of simple erosions of the cervix that are sacrificed, in which complete hysterectomies are performed, that never had a single symptom of cancer. That should be thoroughly emphasized and the general practitioner should be asked in every case, before advising an operation that a thorough examination with the microscope should be made before an operation is decided on.

Dr. Charles L. Bonifield, Cincinnati—Dr. Goelet spoke of the necessity of educating the general practitioner to make an early diagnosis of cancer. It is my opinion that the general practitioner has been educated along this line, but that we must continue the education in another direction. We must educate our patients to apply for relief earlier. I have often had patients sent to me the day after they first consulted their family physician, and on examination I found them too far advanced for operation. As Dr. Baldy said, the question is a practical one; the result we should aim to obtain is to prolong life and relieve suffering. Until our friends who advise the very radical operation of removing all the glands they can find in the pelvis can prove by their statistics that they succeed in doing this, the majority of us will continue to perform the milder operation and give relief from symptoms.

As to the question between abdominal and vaginal hysterectomy, I am a decided advocate of the abdominal method; in fact, I have never done a vaginal hysterectomy. My reasons are briefly these: When the abdomen is opened, we can at once see whether there is involvement of the peritoneum between the uterus and bladder or between the uterus and rectum; if there is, a hysterectomy will do no good and the patient may be spared the dangers and discomforts of the operation; again, we may find that what seemd to be a thickening of the peritoneum from advance of a malignant disease is an inflammatory condition of the appendages having nothing to do with the cancer, and not being a contraindication to hysterectomy; in the abdominal operation we can go wider of the disease, especially in the broad ligaments, and there is less danger of soiling the field of operation.

Dr. G. J. Engleman, Boston—I have never published my results in operative work or in cancer of the uterus; as from the very beginning they have been such as they are described here to-day and now generally acknowledged, unfavorable. I never cured a case, and I deemed myself at fault somewhere, since successful and permanent results were recorded on all sides. My first hysterectomy for cancer, done twelve years ago and then most disappointing to me, is a fair sample. I found the patient improved at first, much improved; then a recurrence, and in less than a year speedy death. I was greatly interested and very much gratified at the tone of the present discussion, because formerly statements were made on all sides of success and cure, and I was unwilling to give my decidedly different and unfavorable statistics. Now, all admit precisely such results. We owe an acknowledgement to Dr. John Bryne, of Brooklyn, for his faithful work. We have doubted him and have watched him. He has gained better results with his method of amputation with the thermocautery than we have from hysterectomy. We have appointed committees to observe his work and the report on it found no flaw. Our observations to-day establish the correctness of his results and his views. We are now getting down to bed-rock; we are at last reaching the position in this question of hysterectomy for cancer of the uterus, that which was taken 75 years ago. We advocate removal in the early stages, claiming only that it will give the patient comfort for a time and then a rapid passing away. This was clearly stated by Sauter in 1822 as the result of a detailed study presented to the Academy of Medicine of Vienna. He takes precisely the position we hold to-day, but, like so much in medicine that is in advance of its time, it was ignored and lost. Hysterectomy in 1822 was a step even beyond the ovariotomy of McDowell, too progressive for the surgery of that period. Now, however, it merits our attention, especially since results and possibilities are there described, as we have only this very last year learned to admit, that temporary relief only was afforded by hysterectomy. Let us do justice and honor to the man who for so many years recognized the truth and staunchly, single-handed, maintained it.

Dr. P. A. Harris, Paterson, N. J.—I simply wish to refer to one point which I believe to be the most important item for our consideration, and that is the early detection of cancer. We as a profession are to be blamed for the condition of affairs existing to-day. If there is one mistake which is common, it is for the general profession to wait for the appearance of blood. They wait for hemorrhages. If we wait for them to appear many cases will pass the stage when an operation can do them any good. The cases should be detected early. In this connection I want to call your attention to the pre-existing leucorrhea. When you have bleeding, you often have tissue necrosis, and when this is extensive, you have very general infiltration and the case has passed to the point where anything like a good result is not to be thought of. Leucorrhea in any person, especially one advanced in age, should receive immediate and careful attention. Its cause should be ascertained. We here have a symptom of very great importance, and always preceding spottings and hemorrhage.

Dr. John G. Clark, Philadelphia—Freund, of Breslau, now of Strassburg, put into effect certain theories concerning a new method of operating for cancer of the uterus which was so skilfully planned that it proved to be the basis of all successive methods of abdominal hysterectomy. Up to this time no definitely planned operation for the total removal of the uterus for cancer had been performed, at least along the lines pursued by Freund. In the twenty-two years since Freund performed his first operation many operations and many plans of treatment other than the surgical have been inaugurated. Freund has been a most impartial critic and has never discarded any plan of treatment which promised better results than his own operation. After a careful observation of the various plans of treatment, Freund, in a personal conversation with me some two years ago, said he had returned to the abdominal method as the most radical, so far devised, for the cure of cancer. His indications for operation are as follows: If the cancer is in the early stage, radical abdominal hysterectomy is performed with a view to a permanent cure; if later, he performs vaginal hysterectomy, only as a palliative measure.

Having worked out a plan for the more radical removal of cancer by the abdominal route, I naturally cling to this method in preference to any other, and I have naturally been delighted to hear such a skilful surgeon as Dr. Pryor take such a strong stand in favor of the abdominal rather than the vaginal route. The very fact that he is so skilful and has advocated so strongly the vaginal methods in many other pelvic pathologic conditions renders his opinion of more than ordinary value when he unequivocally declares in favor of some one of the abdominal methods. If we are to follow the well-established surgical rule for the widest possible excision of tissue adjacent to the cancerous focus, it seems to me that Dr. Pryor's position is the only feasible one.

Within the last two months I have had the pleasure of trying Werder's modification of the abdominal method, and so far I have been delighted with it. In carrying out this method, practically the same plan as suggested by Ries, Rumpf and myself, may be instituted in the abdominal part of the operation. This insures the most radical removal of the diseased tissue and glands within the pelvis. After the uterine arteries are ligated well out toward their origin beyond the ureters, and the broad ligament with its cellular tissue detached from the pelvic wall, the uterus by means of strong traction forceps is drawn down into the vagina, and after whipping the peritoneum together over the pelvic wound the remainder of the operation is conducted per vaginam.

In order to render this operation most effectual I am a strong advocate of the cautery, as advised by Skene, based on Byrne's admirable work. In the cautery we have undoubtedly a better instrument than the knife. The latter cuts through but does not destroy immediately adjacent tissues; the former does both. Microscopic examinations of specimens constantly show that the operation is just within the area of cancerous infiltration and that possibly a very infinitesimally additional removal of tissue might have effected a cure. The careful excision with the cautery may secure this end.

In conclusion, therefore, I feel that a combination of the radical operation as devised by Ries, Rumpf and myself, with the methods of Werder and the use of the cautery for excision rather than the knife, will most nearly effect a radical cure. Even with all this care, our mortality statistics from a continuance of the disease must be tragically high.

Dr. J. Wesley Bovee, Washington, D. C.—I simply wish to cast my opinion in favor of the abdominal route, and I agree with Dr. Clark as to the efficacy of the operation described by Dr. Werder. We all know that in cancer of the cervix the vaginal wall comes in contact with the cancerous tissue constantly. In the operation of Dr. Werder the separation of the uterus and appendages and a portion or all the vagina is all done from above. Then the abdominal wound is closed and from below a circular incision is made around the vagina, meeting the lower portion of the dissection from above by cutting through the vaginal wall and pulling the whole uterus out through the vulva. The whole vagina can be removed in that way. I have now done 14 operations of this kind without one primary loss. Thus far, one case has died from a recurrence. Judging from the description of the symptoms I think it was a cancer of the stomach. This operation extended a little further in the way that Ries and Rumpf have shown, requiring a thorough removal of the lymphatic glands and of all the ligaments of the uterus and the vagina. It is not necessary to introduce the ureteral bougie, as the ureters are easily found and isolated. Chalot, who has done more work than anyone else in this line, ligates the iliacs and transplants the ureter into the rectum or sigmoid, or onto the skin, and removes the bladder. When invaded from cancer of the uterus, it is too late for any radical procedure in the way of extirpation of the bladder or transplantation of the ureters.

Dr. Deaver, in his paper, speaks of these radical operations, comparing the work of the gynecologist and the general surgeon. He speaks of the inguinal lymphatics running to the inguinal glands. I would like Dr. Deaver to say whether or not he removes the inguinal glands in his broad operation.

I wish to say to Dr. Clark that Dr. Sauter has been given the honor of being the first to remove the cancerous uterus through the abdomen, in 1831, but not the first to remove the cancerous uterus.

Dr. Andrew J. Downes, Philadelphia—I had little intention to report what I am going to, because I was afraid I would be premature. During the last year I was working on an electrical forceps with a view to bringing out a more practical and more useful instrument and one that would give us the same results much more quickly than the angiotribe. I have had considerable difficulty with the instrument-makers, as it seems that we can not obtain an electrical instrument as good as we want it. I attempted to procure a forceps that will control hemorrhage in 30 seconds. I now have three forceps, each with one blade on which I can boil a drop of water in 15 seconds. The heat and pressure enable us to control the hemorrhage in 30 seconds. I have operated five times with this forceps during the past winter, although not with the last one I described. I have removed the appendix three times, done one hysterectomy and one ovariotomy. The tissues grasped by the blade are white and there is no hemorrhage. If there is any pus or infected material, as is sometimes found in an appendix, the use of the forceps is not going to endanger the condition, as the forceps are sterile. The point I wish to make is, that with the electro-hemostatic forceps we can control hemorrhages; in cases of cancer we can go close to the pelvic wall and leave a perfectly sterile body behind, which a ligature does not do; what it once compresses remains compressed; if heated sufficiently it will also sterilize the tract through which it passes.

Dr. L. S. McMurtry, Louisville, closing the discussion—I take it that the discussion has thoroughly demonstrated that treatment of cancer of the uterus, is, in the present state of our knowledge, unsatisfactory. It is apparent that in prognosis and treatment we should discriminate between cancer of the cervix and cancer of the corpus. Some of the operations that have been proposed are not applicable in this disease in a large proportion of cases, because these patients will not bear prolonged surgery. A woman who has been depleted by hemorrhage or sapremia, as most of them are who apply for relief, is not in a condition to undergo an operation which will require two hours' time. I take it that Dr. Pryor operates only in cases in the early stage before there is marked constitutional poisoning.

The point I wish to emphasize is that more stress should be laid on minor gynecology. Women, about the menopause, should be invariably examined and minor operations and treatment of inflammatory diseases should receive careful attention, especially as a prophylactic measure.

Dr. R. B. Hall, closing the discussion—I agree with the gentlemen who have said that we should always conserve human life, that we should do for our patients that which will give them the best chance to live. If they can not make a perfect recovery, do the least operation which promises relief. When I agreed to write on this subject it was not an unpleasant duty, as I have always advocated, for certain selected cases, the use of the ligature in preference to the clamp for the reasons stated in my paper. It gives an opportunity to close the peritoneum and thus prevent infection and the possibility of a subsequent intestinal obstruction, which the gentlemen using the clamp with large quantities of gauze packed in the pelvis must admit is not an imaginary danger. I admit that I frequently do the combined operation for cancer of the body of the uterus, particularly sarcoma. The uterus is too large to remove through the vagina, but in those cases in which you can get outside of the diseased area the vaginal route is to be preferred. It is not such a severe operation and the patients recover easier than those that are subjected to the abdominal operation. I believe that the curette and the cautery have a field in these operations, not as a cure, but to prolong life, and to mitigate suffering. I frequently employ them, but I can not agree to the statement made by one of the gentlemen that that is the operation to be advised as a hope of a permanent cure. As to a permanent cure, I do not suppose that my experience differs very much from that of any other gentleman. The large majority of these patients are dead within three years after operation, although occasionally one lives a little longer. I have cases now, cases of epithelioma who are alive after six years. In one case I at first refused to operate, but finally consented to curette and use the cautery. After cleaning up the field, I decided to do a vaginal hysterectomy. The patient is still alive after six years, but it is a rare case. Recurrence is the rule, and it makes me hesitate to perform the radical operation advocated by some of the essayists.

Dr. W. H. Humiston, closing the discussion—My practice for several years has led me to this conclusion: It is necessary in all chronic diseases of the uterus to carefully examine microscopically all tissue removed. If malignant disease of the cervix is found, abdominal hysterectomy gives the best results. If malignant disease of the fundus alone is found vaginal hysterectomy is the better operation.

Dr. William R. Pryor, closing the discussion—I wish to say a word about curettage and removal of portions of the cervix for purposes of diagnosis. The surgeon who purposes to do this should have a clear understanding with his patient that if he finds cancer present he shall have the privilege of performing a radical operation within two weeks; for the man who puts a knife into a cancer focus disseminates cancer cells, and, unless an incomplete operation is very soon followed by a radical removal, his patient is made worse by the interference. The glands which I seek to remove in cancer of the cervix are those which lie near the obturator foramina, and I do not think that any operation for cancer of the cervix should be considered complete which does not accomplish the removal of these glands, together with all of the parametric tissue.

Dr. Deaver, closing the discussion—Notwithstanding that I am a general surgeon, I am more of the opinion than ever that the operation I advocate should be done prior to the infection of the glands. The great point is to have a definite idea of what you are going to do and then go ahead and do it. I have never had any difficulty in dissecting out the glands along the iliac arteries, as they are easily exposed. The curette and cautery is the operation par excellence in advanced cases, beyond any question of doubt. I recall a lady who was operated on four times by this method and lived for five years. I am sure that if she had had a radical operation earlier it is possible the ultimate result would have been better. What prompted me to do this work, so far as the glandular dissection is concerned, is what prompts me to do the radical breast operation. Doing general surgery for twenty years, and doing much breast work, I naturally followed the extensive dissection carefully. I operated on a case twenty years ago and the woman still lives. Of course, many cases recur. Dr. Cartsens says, make a careful prognosis; I say, make a correct diagnosis, that is the principal thing. All those who know anything about the anatomy of the breast know that the mediastinal glands may become involved, if the disease is allowed to advance; therefore, early operation and removal of the glands in the armpit before involvement is necessary. That is my practice.

So far as the anatomy of the glands is concerned, I did not say that I dissected out the inguinal glands when removing the uterus. We all know that within the pelvis we have the iliac and lumbar glands, which go to the receptaculum chyli. Those glands are the ones we must remove. If we can recognize our signboards, our anatomical landmarks, if we know the anatomical relation of the pelvic structures, it is no trouble whatever to dissect out the glands.

In regard to the general surgeon doing gynecological operations, I quite agree that the majority of them should not do such work, but these operations are so easy, so simple in comparison to those of general surgery, that I can not help but be attracted by them. I would like to see some of the gynecologists remove a large cystic or vascular goiter; why, many of them would perish—I mean the gynecologists.

THE ETIOLOGY OF SCARLATINA.

WILLIAM J. CLASS, M.D.
Medical Inspector Chicago Health Department.
CHICAGO.

In the *Berliner Klinische Wochenschrift* of July 2 and 9 there appeared an article by Adolph Baginsky and Paul Sommerfeld, in which they announce the discovery of a micro-organism whose constant presence in the throat secretions and blood of scarlet-fever patients causes them to believe that it is probably the causative factor of this disease. It is this article that has inspired me to a further communication, as well as a desire to present to the medical profession the evidence that has so far accumulated favoring the view that the diplococcus scarlatinæ, the germ discovered by me. is the cause of scarlet fever. The only notice taken by Baginsky and Sommerfeld of my investigations into the cause of scarlet fever is the statement that I had found a diplococcus resembling a very large gonococcus, which organism was considered by me as being the cause of scarlet fever. As the source on which this statement was based, they mentioned an editorial on the subject which appeared in the London *Lancet* of November 18, 1899. This editorial dealt with a preliminary report made on the subject under consideration. I mention this fact, not because I feel in the least hurt by receiving such scant consideration at their hands, but for the reason that if they had taken the trouble to read some of the later contributions by myself and others on the diplococcus scarlatinæ they would not have failed to notice the similarity in many particulars of this germ with the one whose discovery they announce. I do not presume to state positively that these two germs are identical; in fact, this would be almost impossible without having seen their cultures, but I will take the liberty to compare certain parts of the description of their organism with those made of the diplococcus scarlatinæ. The reader may then judge for himself whether there is any similarity or not. In order not to be accused of any inaccuracies or twisting of terms, I shall give Baginsky and Sommerfeld's statements in German exactly as they appeared in their article. Before beginning this comparison, however, I will say a few words in regard to the term "streptococcus."

In recent medical literature, it is quite common to find an organism described as a streptococcus when a culture shows short chains of three or four cocci mixed with single cocci. I have even seen an organism described as a streptococcus where an examination showed perhaps one or two short chains in a microscopical field filled with single cocci. It appears to me that the term "streptococcus" should be reserved for an organism the cultures of which show the chain form predominating, the chains being well defined and not simply an accidental arrangement of three or four cocci of perhaps different size and shape. In ordinary life one would hardly call three pieces of iron, each of different size, when joined together a chain. This statement is made because we are about to deal with an organism that has been described as a streptococcus, but which does not seem to conform with the proper conception of the term "chain coccus."

Baginsky and Sommerfeld describe the morphology of their germ as follows: "In direkten aus Blut in den Organen entnommenen Trockenpræparat erkennt man zu 2-3 gelagerte runde Keime, also Diplokokken oder kuerzeste Ketten, hie und da auch wohl als Tetraden gelagert."

In an article published by me[1] I made the following statement in regard to the diplococcus scarlatinæ, under the heading "Morphology": "In young cultures grown from the blood of a scarlet-fever patient the germ is usually seen as a diplococcus, both segments of which are globular. Streptococcus forms are occasionally, though rarely, met with, as are also single cocci." "Tetrads are frequently seen, and probably denote the beginning division of the organism." It would be very peculiar if two observers who have each examined over three hundred cases of the same disease should find two entirely different germs whose morphology at the same time bore such close resemblance. So much for the primary blood examinations. As we continue our comparison, certain discrepancies apparently appear. I shall again quote from the article by Baginsky and Sommerfeld: "Die Morphologie des so dargestellten Mikroben ist folgende: von wechselnder Længe; in solchen von 3-4 Individuen, indess auch in langen geschlængelten Ketten bis zu 50 Gliedern und barueber, der Keim des Streptococcus ist meist kreisrund, zuweilen allerdings auch abgeplatten und zwar in der Richtung senkrecht zur Kette, so dass zwei mit den breiten Seiten aneinander liegen. Studiert man einzelne Glieder der Ketten genauer in gefærbten Præparaten so erkennt man vielfach Diplokokkenformen, indess nicht immer, andere erscheinen also kleinere oder groessere runde Koerner. Die Form war wie man erkennt æusserst wechselnd und wandelte sich je nach den Medien, in welchen die Cultur weiter poussirt wurde. In direktem Præparat als Diplokokken aufgetretene oder als kurze Kettchen erscheinende Formen wuchsen in alkalischer Peptonbouillon zu langen Ketten, die z. Th. bei der Umzuechtung auf Agar und bei der Thierpassage sich wieder in kurze Ketten von 3—6 Gliedern unwandeln lassen. Hierbei variirte auch die Groesse des einzelnen Keimes aus demselben ursprueglichen Stamm in mannigfachster Weise." In the article referred to[2] I made the following statement in regard to the morphology of the diplococcus scarlatinæ: "A diplococcus polymorphous in character, but resembling, as ordinarily seen in slides made from fresh cultures grown on *my medium* (earth agar), a very large gonococcus. This biscuit-shaped appearence is best seen in specimens that have been but lightly stained. Tetrads are frequently seen, and probably they denote the beginning division of the organism. In very old cultures grown under favorable conditions it shows as an enormous coccus have a slight cupped appearance, the dividing line between the two portions being very indistinct in the more deeply stained specimens. By the division of the large diplococcus a number of smaller organisms are formed, which group together and do not appear as diplococci during the very early stages of their growth." This description of the organism was made from cultures grown on earth agar, while that of Baginsky and Sommerfeld showing long chains was made from cultures grown in alkaline pepton bouillon (*vide ante*). It is of importance to remember this fact, as the morphology of the germ varies according to the medium in which it is grown. ("Die Form war wie man erkennt æusserst wechselnd und wandelte sich je nach den Medien in welchen die Cultur weiter poussiert wurde.") It is this great variability in form when grown on other media than earth agar which caused me to think—as I mentioned in the article in the *New York Record*—during my early experience that the growth upon plain agar, etc., was a contamination. Jaques[3], who studied cultures of the diplococcus scarlatinæ grown on the ordinary media, says in regard to its morphology: "This germ has a wide morphology. Sometimes one stage and then another will become accentuated, according to the environment and nutrition. Sometimes conditions are favorable to its growth in chains and the culture will show streptococcus form. In another case it will grow as a staphylococcus, and still in another as a diplococcus." This variability of form which characterizes my germ, as well as that which Baginsky and Sommerfeld claim as a new discovery, is further shown by the description by Gradwohl[4] of the diplococcus scarlatinæ, who states that it shows no permanence of morphologic character, as well as by the following statement made by me in an article[5] on the subject. "This germ varies greatly in size and shape, and although the form usually seen in primary cultures grown on the earth agar is the diplococcus resembling a very large gonococcus, still a primary culture may show it in one of its other forms.

In order to prove the identity of the organism it becomes necessary to make successive transplantations of the culture from one tube to another, allowing it to grow for a few days at the least before transferring to a fresh tube. The different forms can be best studied by beginning with a culture of the large diplococcus, by transferring a loop of this culture to another tube of earth agar and allowing it to grow for a few days, and then making an examination of the growth it will be found to consist largely of tetrads; by the still further division of the tetrads in the next subculture small diplococci are formed, and through the division of these single cocci, etc." Another point of semblance between these two findings is the variability in virulence which both germs seem to possess in common.

Baginsky and Sommerfeld state, "Bei allen Thieren war die Virulenz eine aeusserst variable," and again, "Die Virulenz der Kokken ist nicht nachhaltig und geht leicht verloren, verminderte sich zumeist schon erheblich nach wenigen Tagen." This is a fact to which I have repeatedly called attention when speaking of the diplococcus scarlatinæ. I will not attempt to draw any comparison from the biologic characters of the two germs, as the following statement by Baginsky and Sommerfeld excludes such a course: "In unseren eigenen Culturen waren wir vergeblich bemueht gewisse Eigenheiten des Wachsthums in den einzelnen Staemmen zu fiziren; immer wieder variirte ebensowohl der einzelne Keim der Ketten in Form und Groesse, wie auch die Virulenz und selbst das biologische Verhalten in den Naehrmedien, so dass wir die Differenzirung einzelner Formen schliesslich auszugeben gezwungen waren." In looking over the comparison made in the preceding pages I think the reader can not fail to be impressed with the fact that in all probability the germ found by Baginsky and Sommerfeld in their primary examinations was identical with the diplococcus scarlatinæ, as the description given of it by them and my description of the germ as seen in primary cultures have almost the same wording. Of course, a point of difference is that Sommerfeld and Baginsky, in the description of the growth of their germ on agar, etc., speak of it as a streptococcus, while this term can not be applied to the diplococcus scarlatinæ as ordinarily seen. However this may be, the germ found by Baginsky and Sommerfeld in their primary blood examinations was certainly not a streptococcus, but a diplococcus, as they themselves say, "Zu zwei bis drei gelagerte runde Keime also Diplokokken oder kuerzeste Ketten." If a germ which shows such an arrangement is a streptococcus, why, then, every known coccus is a streptococcus. In their further description they speak of chains containing fifty or more cocci being found in their bouillon cultures. Such lengthy chains my diplococcus scarlatinæ never forms, and from an experience based on the examination of hundreds of cases of scarlet fever I feel justified in stating that a long streptococcus, an organism to which the name streptococcus can be properly applied, can *not* be found in cultures made from the blood of an uncomplicated case of this disease. If it is present, it is a sign either that the case is not an uncomplicated one, or that the culture is contaminated. The impression made upon me by the reading of Baginsky and Sommerfeld's paper was, that they had in their culture the diplococcus scarlatinæ mixed in some instances with a long streptococcus, the presence of which was accidental. Streptococci are present in the pharyngeal mucus of a certain proportion of cases of scarlatina, but not by any means invariably, nor do they ever compose the bulk of the culture. So much for the present in regard to the discovery of Baginsky and Sommerfeld. Let us now consider the evidence in favor of the view that the diplococcus scarlatinæ is the cause of scarlet fever.

1. *Evidence showing that the diplococcus scarlatinæ is a germ not heretofore described.*—In March, 1899, at a meeting of the Chicago Medical Society, I presented a preliminary report, together with a demonstration of specimens of a germ whose constant presence in a series of about thirty typical cases of scarlet fever had led me to believe that it was probably the cause of this disease. This germ, when grown upon a medium especially devised by me, showed certain peculiarities in its morphology—very large gonococcus form—and growth whereby it could be distinguished from other germs. A very careful and exhaustive search in bacteriological literature made prior to this announcement had failed to show the description of any germ resembling the one described by me. Since this preliminary report was published I and others have further elaborated the matter without finding anything conflicting with it. It is true that the large gonococcus form is not a constant feature of this organism, nor did I ever claim this to be the case; but it is the usual form seen when grown on the earth agar and one which serves to distinguish it from other organisms. This form, if not present in the primary cultures, can always be obtained by successive transplantations on the earth agar[6]. A full description of the different forms of this organism appears in the June issue of *Medicine* and in the *New York Medical Record,* September 2, 1899. Numerous findings of diplococci and streptococci in scarlet fever had been recorded before I announced my discovery, and may give rise to the view that I presented nothing new. While it is possible that some of these discoverers really had the diplococcus scarlatinæ in their cultures, they at best only described one of its forms, and none prove the constant presence, or the relationship, of the germ to the disease. Neither did they reproduce the disease or show any way by which the germ could be distinguished from others. Thus Crajkowski[7] in 1895 announced that he found diplococci in the blood of sixteen cases of scarlet fever; this organism presented nothing characteristic, nor did Crajkowski follow up his examination as far as can be seen by searching the literature on the subject. That the diplococcus scarlatinæ is a *new* germ is further shown in an article by Gradwohl,[2] who gives a very good description of its biological characters.

2. *Evidence showing that the diplococcus scarlatinæ is constantly present in scarlet fever.*—The presence of this germ in cases of the disease has been well proved. Thus Gradwohl[8] found it in seven consecutive cases, Jaques[2] demonstrated its presence in every one of a large number of cases examined. The writer announced before the Chicago Pediatric Society in December, 1899,[10] that he had found it in three hundred successive cases of scarlet fever and scarlatinous sore throat. Page,[11] of Boston, announced that he had found a germ corresponding to the description of the diplococcus scarlatinæ in a number of cases. Besides these published findings, I have personal knowledge of its having been found in the blood, throat secretions and scales of scarlet-fever patients by a number of other competent observers whose results have not as yet been published. These results have been so uniform that I am absolutely certain of my ability to demonstrate the presence of the diplococcus scarlatinæ in the blood, throat secretions

and scales of every typical case of scarlatina given me for examination.

3. *Evidence showing that the diplococcus scarlatinæ is a pathogenic micro-organism.*—This germ is pathogenic for mice, swine and guinea-pigs. Mice are most susceptible, and a small quantity of a virulent culture injected subcutaneously will sometimes kill the animal in an hour's time. As a rule, death takes place within twelve hours of the time of inoculation. Swine, as a rule, show no reaction from the subcutaneous injection, unless a very large quantity of a virulent culture is used. Swine are known to be insusceptible to the influence of most pathogenic germs when injected subcutaneously. Even the bacillus of hog cholera produces but little effect when administered in this manner; therefore it is not surprising that the diplococcus scarlatinæ is not very pathogenic when injected subcutaneously. Intra-abdominal injections give rise to grave symptoms, and if a sufficient amount of a virulent culture is used it will cause the death of the animal. The usual method which I have used in order to produce typical symptoms of scarlet fever in swine has been to inject a culture grown on agar and mixed with sterilized water directly into the circulation. For this purpose either the ear veins or the femoral veins were used. The amount of culture used for these experiments varied according to its virulency, usually, however, one cubic centimeter was sufficient, and in some instances caused the death of the animal a few days subsequent to its injection. Guinea-pigs usually succumb to the intra-abdominal injection of 0.1 c.c. of a virulent culture. During the first few days after inoculation these animals usually showed but little signs of sickness; then they began to refuse food, gradually became more and more emaciated, and death occurred as a rule ten to fourteen days after the injection was made. Subcutaneous injections generally were without result. These observations have to a great extent been verified by the experiments of Gradwohl.[12] Rabbits and white rats appear to be but slightly, if at all, susceptible, while cats and dogs are immune. The diplococcus could, as a rule, be easily obtained from the organs of the susceptible animals after death, and from their blood during life. Cultures taken from the blood of the ventricles and from the spleen generally showed a pure growth.

4. *Evidence showing that scarlet fever can be reproduced in animals by the diplococcus scarlatinæ.*—The diplococcus scarlatinæ is the first germ that has ever been discovered through whose agency a disease has repeatedly been produced, which has been recognized by competent men as being apparently identical with scarlet fever as it appears in human beings, so far as the rash and scaling are concerned. The animals used to reproduce the disease were white swine. When such an animal receives an intravenous injection of a virulent culture of the diplococcus scarlatinæ it will usually sicken within a few hours, there will be a rise in temperature, the animal will become restive and refuse food; after three or four days, as a rule, a decided reddening of the skin will appear, which lasts from one to two days, to be followed within a week to two weeks by profuse scaling. Sometimes the eruption is more of a papular character and the reddening not well marked, but usually it can be easily demonstrated, especially if the color of the animal is compared with that of one in good health. The disease has been reproduced by the author in a considerable number of swine, the number being large enough to exclude the possibility that it was merely an accidental phenomenon. These results have been further verified by Gradwohl[13] and Jaques.[14]

5. *Evidence showing that the pathologic changes in the organs, caused by the diplococcus scarlatinæ resemble those of scarlet fever.*—As an example of the gross changes produced by the diplococcus scarlatinæ I will give a brief statement of the findings in a young pig which was inoculated in the pathological laboratory of Rush College, Feb. 17, 1900. About 1 c.c. of agar-culture was rubbed up with 5 c.c. of sterilized water and injected into the femoral vein. On February 24 the animal was found dead, and on post-mortem the following changes were found: "Spleen is enlarged and congested; Malpighian bodies stand out prominently. Kidneys show cortex pale in color, with a few small hemorrhages near surface; capsule comes off easily; pelvis of kidney is congested and drips blood on section; pyramids stand out plainly. Liver shows numerous whitish necrotic areas and is congested; blood drips on cutting. Lymphatic glands of neck are enlarged, varying in size from a Lima bean to that of a hickory nut. Slight amount of effusion appears between layers of pericardium. Walls of intestine are congested, and show numerous hemorrhagic spots. Other organs are apparently normal." The mice and guinea-pigs that were examined post-mortem also usually showed gross signs of nephritis. In regard to their other organs, nothing positive could be stated on a macroscopical examination. The organs of a considerable number of animals were preserved for microscopical examination, the results of which will be reported later. Gradwohl has confirmed the occurrence of nephritis in swine and guinea-pigs after inoculation with the diplococcus scarlatinæ.

6. *Evidence showing that the disease produced through the agency of the diplococcus scarlatinæ is of a contagious nature.*—There are a number of facts on record which go to prove that this germ produces a contagious disease. Thus, Jaques[15] stated that when a healthy pig was placed with two pigs that were scaling after having been inoculated with the diplococcus, it developed a rise in temperature lasting several days, followed by scaling, thus showing that it had evidently contracted the disease by contact. Gradwohl, in an article previously quoted, states, that if a healthy mouse be put in a cage in which another mouse that has been inoculated with the diplococcus scarlatinæ has been kept, the healthy mouse will sicken and die and will show the diplococcus scarlatinæ in its organs post-mortem. I have seen similar results occur a number of times while carrying on my own experiments, and I think that it must be admitted that the contagious nature of the disease produced is extremely suggestive and speaks strongly in favor of the claim that the diplococcus scarlatinæ is the causative factor of scarlet fever.

7. *Influence of blood of scarlet-fever patients on the activity of the germ.*—Under this heading I will quote a few experiments described in an article[16] by me, to-wit: "A loop of pure culture of the diplococcus was diluted with fifteen minims of distilled water. One half of this was poured over a plate of glucose-agar, to the other half were added ten drops of blood from a patient who had just recovered from an attack of scarlatina, and this mixture was poured over a similar plate. Both were put into an incubator, the temperature of which was kept at about 36 C. At the end of twenty-four hours the plates were removed. The plate made from the culture without the addition of the blood showed innumerable minute colonies of the diplococcus, while on that to which the blood had been added there

were only a very few colonies. Presumably these had grown, because from the tendency to clump, some of them had not been exposed to the action of the blood. This experiment was repeated five times with almost identical results. Each time there was a slight growth of the culture to which the blood had been added, but the growth was so much more profuse in the one without this addition, that the inhibitory action of the scarlet-fever blood on the growth of the germ could be plainly demonstrated. Blood from a child 5 months old, where the possibility of a prior infection with the germ could safely be excluded, produced no inhibitory action. The other experiment consisted in inoculating four ordinary gray mice, each of which received five minims of a solution of a virulent culture of the diplococcus scarlatinæ in distilled water. Two of the mice had previously received, by subcutaneous injection, five minims each of blood-serum taken from a patient recently recovered from scarlet fever. The two animals that had not received the blood inoculations died within eighteen hours, while of the two that had been injected with the blood, one lived about forty and the other seventy-two hours." These experiments have since been repeated a number of times with practically the same result. In making the first set of experiments quoted, it was also necessary to use a virulent culture, as one that has been grown a long time on artificial media is not so sensitive.

8. *Finding of the diplococcus scarlatinæ in throat secretions of patients with scarlatinous sore throat, a further proof of its specific character.*—In an article on the etiology of acute tonsillitis,[17] I made the following statement regarding the diplococcus scarlatinæ: "It is not only invariably present in the angina of scarlet fever, but during an epidemic of this disease it will frequently give rise to an acute tonsillitis without any eruption, although not infrequently these cases are followed by a nephritis and sometimes by desquamation. It may sound like a bold statement to make, nevertheless I am fully convinced that a person who has had an attack of acute tonsillitis due to the diplococcus scarlatinæ, is rendered immune against scarlet fever; or, in other words, that this form of angina is nothing more or less than scarlet fever without the presence of an eruption." And further, "the contagion from a case of scarlatinous sore throat is capable of giving rise to typical scarlet fever in another person who has been exposed to it." The occurrence of scarlatina sine eruptione is something that has for a number of years been accepted, more or less generally, but it could not be proved positively, as the causative germ of scarlet fever was not known. Admitting for the present that the diplococcus scarlatinæ is the cause of scarlet-fever, it will be found that during an epidemic of this disease cases of scarlatina sine eruptione are of far greater frequency than has generally been supposed to be the case. Your skeptic may cry out, that the finding of the diplococcus scarlatinæ in so many cases of apparently simple sore throat speaks strongly against its being a specific micro-organism. On the contrary, it is just this fact which goes a long way to prove its specific nature. If it was only present in typical cases of scarlet fever, how could we explain those cases in which one child in a family has scarlet fever, while several others at the same time develop only a tonsillitis, followed perhaps by nephritis and desquamation. The contagion must necessarily be the same, for frequently these cases of angina give rise to an attack of typical scarlatina in another member of the family. Furthermore, if these cases of angina were not scarlatina sine eruptione, how could we account for the fact that so many people escape scarlet fever. The finding of the diplococcus shows that they had in the majority of instances been rendered immune by an attack of angina caused by this germ, and that the eruption of scarlet fever is simply one manifestation of the activity of this micro-organism. The presence of an eruption is not absolutely necessary to make a diagnosis of scarlet fever, however inconsistent this may seem when the name of the malady is considered.

9. *Growth in milk without affecting this medium a fact in favor of its being the cause of scarlet fever.*—In speaking of the diplococcus scarlatinæ, an editorial in the *Interstate Medical Journal*, March 1, 1900, states: "It is interesting to note in the description of the biologic characteristics of this diplococcus scarlatinæ that the micro-organism grows in milk, but does not produce any visible change in it, such as coagulation or digestion, etc. This will serve to explain the dissemination of this disease, which has been from time to time traced to the infected milk. It is important from a public-health standpoint. And the fact that cows are known to be susceptible to scarlet fever, taken into consideration with the fact that the diplococcus scarlatinæ is probably excreted in the milk of these animals, will explain how this milk which spreads the disease is infected. Of course, it might also be infected by means of contamination with the hands of patients with scarlet fever, or from milkers or dairymen in whose families scarlet fever is present."

10. *Finding of the diplococcus scarlatinæ in cases of surgical scarlet fever demonstrates its diagnostic value.*—In the May number of the *Chicago Medical Recorder* for 1900, there appeared a report of a case of double cryptorchidism complicated by scarlet fever, by Dr. Edward Ochsner. The patient, eighteen hours after the operation for the relief of his trouble, suddenly developed a high temperature, together with vomiting. On the following morning the patient showed a scarlet rash all over his body. The only thing that had come in contact with the patient prior to the appearance of the rash were saturated solutions of boracic acid and alcohol dressings, no iodoform being used. The question naturally arose whether the rash was of a simple septic nature, or true scarlet fever. I made cultures from the blood, obtaining a pure growth of the diplococcus scarlatinæ. A similar finding was obtained from the patient's urine, which showed traces of albumin. Subsequently, the patient scaled. Since the publication of the above report I have again had an opportunity to examine blood and throat cultures taken from a patient developing a sudden rise in temperature and scarlet rash after a slight operation upon the heel. The result of the examination of these cultures also showed the case to be one of scarlet fever. I mention these cases, because in all probability a large number of cases of so-called septic rashes are nothing more or less than true scarlet fever.

In concluding, I wish to state that all the experiments quoted are open to investigation, and that I feel confident that unprejudiced and painstaking investigators will further confirm what has been said. Allowing that these statements are based upon facts, I think it must be admitted that the diplococcus of scarlatina fulfills all of Koch's laws, and is therefore entitled to some consideration at the hands of those engaged in a search for the solution of the etiology of scarlatina.
